Modern Mining Methods.

"Mining methods" is a subject always of interest to the miner, and in the United States, where the wage rate is relatively high as compared with that of Europe and most Spanish American countries, certain methods employed in those countries are only mechanically applicable in America, as their employment here is rendered inexpedient, owing to cost of labor. This fact has rendered the square set system of timbering indispensable to American mines. In fact there are many large ore bodies that could not without great danger and probable loss of ore be extracted by any other method. This system is elastic and can be so adjusted as to meet almost any condition, but to insure the greatest good it must be properly applied. That the square set can be put in roughly and still be expected to meet all requirements is a mistake. It must be placed with great care and absolute exactness to insure the best results. In only a few mines is it not necessary to fill the stopes as fast as timber is put in place. A notable exception was the Ophir mine on the Comstock where P. Deidesheimer first introduced the system, it being really the outgrowth of the necessities of the case. In this mine Mr. Deidesheimer extracted a stope 400 feet high, 90 feet wide and 320 feet long, the entire excavation being filled with square sets, the whole presenting as much regularity of appearance as the steel frame of a great modern building in course of construction. The work was well done, however, and the greatest care was taken that all wedges be tightly driven, allowing the ground no opportunity to start. This stope was extracted and timbered in 1861, and was filled from the surface in 1862. It was a thoughtfully planned and carefully executed piece of mine engineering, under almost ideal conditions, but these ideal conditions are rarely found and filling must be resorted to promptly. There are few stopes of such magnitude as that of the Ophir that will stand a year without filling. The greater number demand that filling be carried on contemporaneously with ore extraction and timbering.

When agitation was made some years ago for a much needed Cabinet department of mines and mining, the movement was partially sidetracked by the

suggestion from sundry Western Senators that a "bureau of mining" could or would be embodied in the to-be-created Cabinet department of commerce. The bill creating the Cabinet department of commerce comes up next week for the consideration of Congress, but among the many "bureaus" it is designed to embrace there is no mention of mining or metallurgy. Meanwhile there is a growing need for a Cabinet department of mines and mining, and nothing less will give proper representation to that great national industry.

Old and New Methods in Mexico.

Nothing, perhaps, can better illustrate the advance of modern ideas into the mining districts of Mexico than the two half-tones appearing on this page. One is a heavy, ungraceful structure of wood,

standing at the collar of the old Valencia shaft at Guanajuato, the other a graceful steel frame, erected at the Real Del Monte mine, in Pachuca, State of Jalisco. The latter illustrates the adoption of modern American methods, structures and machinery. The former, however, conveys little idea to the observer of the character of the great shaft over which it stands at Guanajuato. The shaft is vertical, circular in form, 30 feet in diameter, 1600 feet deep, and walled with masonry from top to bottom—a remarkable piece of engineering to be accomplished by any people in any age.

Most interesting to contemplate is the remarkable changes and improvements made in metallurgical processes and machinery within the past twenty-five years. This is more particularly noticeable and important in smelting. Furnaces have been changed in form and have grown in size until the lead or copper furnace of a quarter of a century ago looks like a pigmy beside one of modern type. The hard and fast "laws" governing the technology of smelting have been displaced by newer and better methods, and to-day smelters are successfully operated with a less percentage of lead, or of copper, and with lighter fuel charges than ever before. Copper mattes are now made containing no more than 5% copper, which has taken up practically all the precious metal in the ore. At well appointed works everything is done on a scale eclipsing the magnitude of anything attempted a few years ago. Mechanical haulage has been introduced to handle the products of the furnaces, and the tendency is still along the same lines of expansion and improvement.

In the case of the Kennedy Mining Co. vs. the Argonaut Mining Co., of California, now under consideration by the Supreme Court of the United States, one of the questions is that of jurisdiction, motion having been made to dismiss the suit for lack of jurisdiction. A decision is expected this month, when the court reconvenes.

Vanadium; Buffalo Pitts Road Locomotive; An Ore Chute and Bins, Lassen Co., Cal.; A Type of Desert Deposit, 9. Mining and Metallurgical Patents; Portable Forge, 10. Personal; Obituary; Books Received; Catalogues Received; Commercial Paragraphs; New Patents; Notices of Recent Patents, 15-16.

THE employment of a searchlight at night at the property of the Mountain Copper Co., in Shasta county, Cal., may be considered an indication that the company anticipate trouble, but intend to forestall it as far as possible.

THE good luck of some prospectors is phenomenal. The latest to attract attention is he who in the Thunder Mountain district, Idaho, where the snow is 7 to 15 feet deep, has found a ledge half a mile long and 2000 feet wide that pans in coarse gold. A shaft was sunk 10 feet deep—presumably in the snow.

IN the manufacture of crucible steel the most notable advance is the addition of manganese, ferro-tungsten, chromium, nickel uranium, vanadium or other alloy, producing a property in the steel of requiring no heating nor subsequent cooling in water to occasion hardness, furnishing what is styled a self-hardening steel. With this tool steel of special preparation it is possible for a tool to hold its cutting edge and temper when heated by rapid work to redness. Exact methods of modern metallography make it possible to furnish the most precise and individual requirements of steel users in any department of industrial life.

THE Calumet & Hecla copper corporation stock affords an object lesson in capitalization of mining properties. This company originally incorporated for \$2,500,000, with 100,000 shares, and has never increased its capital stock, has paid \$79,850,000 in dividends to the holders of the stock, and last week the stock was held in the New York market at \$500 per share. It is true this is but a single instance, and indeed may be said to be a single one out of a few, where the dividends have exceeded the capitalization. Why new mining propositions, wholly unproven, should be capitalized for many millions of dollars, is not apparent. The extent and net value of the ore bodies must eventually determine the real worth of the property, and all mining men know this to be so. If the object is to impress the possible investor who has little knowledge of mining, it would seem that such would expect a fair rate of interest on the capitalization. On the whole, it would seem that generally there is really little direct relation between capitalization and actual value of property owned by a mining company.

System in Mining.

IN order to economically work a mine, it must be done systematically. The plan should be carefully studied out, and each idea given due consideration. The haphazard method may pay in a rich mine when it would not pay in one of low grade. To work systematically requires much time in preparation and often it involves what at first appears to be a great and unusual expense, but the final result will prove, if the time and money have been spent judiciously, that it has been economy to follow a system.

Shafts should be made perfectly straight whenever possible, whether vertical or inclined. At times, however, it seems necessary to change the angle of inclination of a shaft, which may be done without material detriment to hoisting operations, though always resulting in increased expense of running ropes and repairs.

Under no circumstances should a shaft be permitted to depart from its alignment—to swerve to one side, as it were, and yet it is no uncommon thing to find this condition in shafts that are otherwise well appointed.

When a level is run, whether directly on the vein from the shaft or from a crosscut, raises should be driven to the level above as soon as possible. This will improve ventilation throughout the level and also affords a good idea of the value of the ore lying in the block of ground through which it passes. When stopes are large and the square set system of timbering is in use, the raise may be either driven directly up on dip of the vein, or it may be sent up at an angle of 35° or thereabouts along the strike of the vein, and this is the best practice. Through a raise of this character all the timber used in the timber system may be sent down from the level above. Signals are arranged to warn workmen, and the timber is shot down, suffering no damage thereby. In some mines these inclined chutes are lined with plank, that no obstruction may be offered to the passage of the timbers. As stoping progresses upward the timber is still delivered at the topmost floor throughout the entire height of the stope, and all hoisting of timbers by hand, or by snatchblocks from the level below—a slow, laborious and necessarily expensive operation—is dispensed with.

Whenever possible, all waste rock resulting from exploration should be employed as filling in mines where filling is necessary. Winzes can be sunk more cheaply with portable hoists, run by either air or electricity, than by hand, and where the levels are a long distance apart—150 to 200 feet—it is economy to hasten the connection between two levels by driving both winze and raise contemporaneously.

Where the main shafts are sunk outside of the vein in country rock provision should be made, if there is much of this work to be done, as 500 feet or more, for dumping chutes at the stations above those levels requiring filling. This requires several hundred dollars outlay in each case, but will abundantly pay, as the waste rock from the bottom of the shaft is hoisted a much shorter distance and is dumped into the bin prepared to receive it. This is withdrawn into a car and trammed to a winze connecting with a stope below the level and dumped into the fill. The rock obtained in this manner from 500 feet of an ordinary three-compartment shaft will fill the space left by the extraction of about 3000 tons of ore from the stope. If the expense of providing means for handling the waste underground does not exceed \$200 it is cheap filling, for it must be remembered that this waste, if not utilized in the manner suggested, must be hoisted possibly several hundred feet more, dumped and trammed on the surface, where it is dumped for no useful purpose, generally. This system has been introduced in the Gwin mine, in Calaveras county, Cal., and is said to work satisfactorily. The Gwin shaft is vertical. It would be more expensive to adapt this system to an inclined shaft, but mechanically it can be accomplished. Its advisability remains for the manager to determine in each case.

Underground haulage is receiving increasing attention, and it is becoming generally acknowledged that the system of tramping with men is not entitled to be called a system at all.

Another feature of underground work which

should receive careful consideration is the tracks. It makes little difference what sort of means is employed for moving cars—men, mules or mechanical power—the tracks must be well laid and kept in good condition as far as possible, and particular attention should be given to turnouts. More time is lost at poorly constructed turnouts in replacing derailed cars than would quickly provide a good turnout.

A volume might be written on mine management—not altogether the office management, but the underground management, though the two are necessarily closely connected. A carefully considered system, wherever adopted, has been found not only to give satisfaction, but to be good business because it pays.

Patented Metallurgical Processes.

THE United States patent affords sufficient protection to a bona fide inventor, whether of a new metallurgical process, or some novel household utensil, and there need be little apprehension of infringement upon these rights without redress. The process inventor who declares he has solved the secret of abstracting precious metals from rock containing them at a cost so low as to be practically nil, or to extract gold and silver from rocks where no one else can obtain traces, and who neglects to patent his invention, but declares it to be "secret," is a fakir. During the time an inventor is experimenting on his invention he naturally attracts as little attention as possible, but having solved the problem to his satisfaction he at once proceeds to patent. The discoverer of a new metallurgical process having real merit, whether to treat gold and silver ores, or those of the base metals, is quickly welcomed in the field of metallurgy, but he must be prepared to do all that he claims for his process. There are numerous valuable patented processes in operation in the mining regions which have stood the test of time and which accomplish under proper conditions what is claimed for them.

THE Supreme Court of Montana has rendered a decision in the Pennsylvania case, which has been under consideration for almost a year. The court affirms the decision of the lower court denying a new trial, but refuses to allow plaintiff's cost bill of \$258,000. An important point is that the Supreme Court holds that a trial by jury in mine litigation is within the discretion of the lower court. To this decision Associate-Justice Pigott filed a dissenting opinion. The Pennsylvania case, as it is known, is the outcome of an action brought by the Montana Ore Purchasing Co. against the Boston & Montana Con. Co., to recover damages for ore alleged to have been extracted from three veins claimed by plaintiff to have their apices within the Johnstown and Rarus claims. It was alleged the ore had been removed through the Pennsylvania workings. The question of extralateral right was an important feature of this case and the court decided that extralateral rights govern unless otherwise stipulated in the deed transferring the property. The decision was mostly in favor of plaintiff, though defendant profits by denial of the large cost bill.

WHATEVER the financial conditions of the country, gold is always in demand, and the gold miner finds in panic or war only an increased demand for his product. Silver has dropped slowly and by bounds from \$1.29 per ounce to 48 cents, and the effect upon the silver miner is to urge him to search for gold, and when he searches for gold he usually finds it—often close at home, where he had not previously suspected its existence. As in the past, we all now naturally expect to hear of the discovery of gold in new and unsuspected places, and in all probability we shall not be disappointed.

THE land department at Washington has issued an order dated Dec. 18, 1902, withdrawing temporarily nineteen townships in Shasta county, Cal., from settlement, entry, sale or other disposal. The order expressly states that this temporary withdrawal will not affect bona fide settlement or valid claim made prior to date of the order. The land is largely covered by forest and it is evidently the purpose of the government to take the necessary steps to preserve as far as possible these forests from destruction.

Concentrates.

STOCK in corporations organized under the laws of California is assessable.

NATIVE ANTIMONY occurs in Riverside county, Cal., near the town of Corona.

THE deepest hole drilled in the United States is the oil well of the Forest Oil Co., West Elizabeth, Allegheny county, Pa., 5575 feet.

PYRITE is used almost exclusively in the manufacture of acid in America, as pyrrhotite—the mono-sulphide of iron—is too low grade in sulphur.

AN association of eight persons may jointly take up 160 acres of placer ground, in which event the assessment may all be done at one place.

BECAUSE dynamite sticks will sometimes burn without exploding, should not lead to the belief that this practice may be indulged with impunity.

PURE lead carbonate is a white mineral unaltered at 100° but converted to protoxide at a temperature approaching redness, carbon dioxide escaping.

ON heating crystallized ferrous sulphate, it loses first its water of crystallization, then sulphurous and sulphuric anhydrides, and ferric oxide remains.

"RAWHIDING," as applied to handling ores in British Columbia, means transportation on animals in rawhide sacks from the mines to smelters or railroad point.

THE "cry" of tin is the name given to the peculiar squeaking sound made by a bar of tin when bent or bitten by the teeth. It is a characteristic of tin which is not known to be possessed by any other metal.

THE manufacture of artificial corundum consists, in a general way, of the conversion of the mineral bauxite (a hydrous aluminum oxide) into corundum by means of intense heat and great pressure in an electrical furnace.

AT the Kohlwald colliery, in the Saar district, Germany, in a crosscut where the ground was bad, and exerted great pressure, the workings were lined with concrete for a distance of 20 meters, and it has proven a success.

NO SULPHURIC ACID is imported to the Pacific coast owing to high freight rates from the East. There are nine different acid manufacturing works on the Pacific coast, and acid is cheaper than in the East, where manufacturers have a working arrangement.

ORE BINS at stations of shafts having a low angle of dip may be provided by cutting out for them in the hanging wall side of the shaft. When the shaft is very flat it may require considerable excavation for the bin and approaches, but if there is much rock to be handled on the level it will well repay the cost.

MOST of the ores containing nickel also contain cobalt. Nickelliferous pyrrhotite, which is the most abundant and widespread nickel ore, contains from one-twentieth to one-thirtieth as much cobalt as nickel. Millerite is a brass yellow or bronze yellow nickel sulphide, often associated in small amount with pyrrhotite.

IN ordinary coal gas are contained various heavy hydrocarbons, mainly ethylene, but also propylene, acetylene, butylene, various members of the paraffine series, etc., hydrogen and carbon monoxide, also smaller amounts of carbon dioxide, oxygen, nitrogen, hydrogen, sulphide, carbon disulphide and allied bodies.

WHERE a vein having a gouge accompanying it, in hard rock, dips out of a shaft being sunk on it, but which does not depart a great distance from the line of the shaft, it will usually be found to be economy to remove all the rock between the vein and the shaft, as the speed made in sinking will more than pay for increased expense of timbering and removing ground.

THE introduction of crude petroleum as fuel in a reverberatory furnace at the Sutter Creek, Cal., reduction works has been found to be advantageous, as it permits a largely increased capacity of furnace, and the flame is so completely under control that a more thorough roasting is accomplished than when wood was used. The tallings are also of lower grade than formerly.

THE richest mines of the Leadville, Colo., district were those on Fryer hill. Noted among them were the Robert E. Lee, Little Pittsburg, Chrysolite and Matchless. The ore was discovered within 30 feet of the surface in the Little Pittsburg, lying beneath gravel of the glacial lake bed which covered that region. None of the ore deposits worked in early days on Fryer hill were deep.

CARBORUNDUM, the new abrasive manufactured at Niagara Falls, N. Y., is composed of carbon and silicon, containing 32% of the former and 68% of the latter. It comes from the electric furnace in the form of splendent crystals and great hardness. It is crushed in rolls into grains of various sizes, washed in a solution of acid and water to remove soluble material, dried and sifted to uniform sizes.

ABRASIVE MATERIALS are divided into three classes—those which occur in rock formations and are cut or manufactured into the form desired, still retaining their original structure, as grindstones, whetstones, etc.; those which occur as constituents of rocks or veins, and have to be mechanically separated from their gangue, as garnet, corundum and emery; artificial abrasives, as carborundum, crushed steel and artificial corundum.

CELESTITE and strontianite are the two principal strontian minerals. Celestite is strontium sulphate and

strontianite is a carbonate of strontium. The characteristic test of the strontium minerals is the deep crimson color given the blowpipe flame. The mineral is chiefly used in making fireworks, strontium nitrate and carbonate being used for this purpose. The oxide and hydroxide are largely employed in the manufacture of beet sugar.

IN the rules regulating the storing and handling of nitro powders and exploding caps at the subway now being built in New York City it is not permitted to keep caps and powder in the same magazine; thawing of powder by bringing it into contact with hot water itself is prohibited; the thawing of powder by steam heat at unknown temperature is not allowed, nor is it allowable to prepare powder, fuse and caps in any building or magazine where powder is stored.

TO ETCH on metals, take 1 ounce of nitric acid and 1 ounce of muriatic acid. Mix, shake well together, and it is ready for use. Cover the place you wish to mark with melted beeswax; when cold, write your inscription plainly in the wax clear to the metal with a sharp instrument; then apply the mixed acids with a feather, carefully filling each letter. Let it remain from one to ten minutes, according to appearance desired; then throw on water, which stops the process and removes the wax.

LITHIUM is chiefly derived from two minerals, lepidolite and spodumene. Lepidolite occurs in California near Pala Mission and at Mesa Grande, San Diego county, and the former is the principal source of lithia in the United States. At both localities mentioned tourmalines of various colors are found. The most noted locality for spodumene is the Etta mine, Pennington county, S. D., where it occurs in six-sided crystals of great size—from 12 inches to 3 feet in diameter and 20 feet or more in length.

TO SECURE uniform temper in working parts of machine drills, the various pieces, nuts, bolts and moving parts of the drill are carefully packed in boneash in a steel box, a cover luted on and the whole placed in a furnace, where it is heated to a bright red. The box is then removed from the furnace, the cover taken off and the several pieces of steel thrown into a tank of cold water as quickly as they can be removed from the boneash. This gives the entire lot the same temper, securing the much desired hardness and uniformity of texture.

THE distinction between a fissure vein and a true fissure vein is not apparent. If a vein occupies the plane of a fissure, whether it have a banded structure or not, it is a fissure. Often the parallelism of bands of quartz and slaty or other soft material, called ribbon structure, is produced by the movement of the vein after the vein was formed. Where there has been much movement in country rock adjacent to a vein, the quartz is sometimes found to have been broken into fragments and recemented by the ground-up material of the vein walls, forming a solid, compact mass.

THE drying of ores by calcining previous to dry crushing sometimes does more harm than good when it is intended to treat them by the cyanide process. Particularly is this the case where the ore contains much sulphide mineral, as the partial oxidation of the sulphides interferes with the operation of the process. Such ores should be dried by being subjected to a long-continued low heat, or be treated to a dead roast, wherein all sulphur is eliminated. This is impossible to accomplish by the continuous kiln process, which requires the ore to be roasted in large lumps, in which condition the heat is insufficient to thoroughly roast the ore.

FINELY pulverized quartz is used as a wood finisher. It is ground, floated, precipitated, dried and bolted, and mixed with the proper proportions of japans, oils, etc., to make a paste. This is reduced with turpentine or benzine, so it will flow freely with a brush, and painted on the smooth surface of wood. It is left until it becomes "set up," which takes from a few minutes to half an hour, and then wiped off the surface, leaving the pores of wood filled with minute particles of quartz which have been carried in by the oil. Wood treated in this manner will take a high polish. Quartz employed for this purpose must be pure and white.

THE death of a miner in the J. I. C. mine in Wasatch county, Utah, by the falling of a crosshead upon him while descending the shaft was probably due to the fact that the crosshead was too short. The height of the crosshead should be at least two times its width, otherwise it may assume a slightly diagonal position while in motion, and on meeting the slightest obstruction or inequality in the guides "hang-up" in the shaft, as in the case above mentioned. The bucket continuing to descend, loosens the crosshead by reason of vibration of the cable, and it falls knocking out the clip and severely injuring or possibly killing any one riding on the bucket.

THE so-called "Mother Lode of California" extends from El Dorado county on the north to Mariposa county on the south, a distance approximating 120 miles. The formations encountered within this distance are chiefly black clay slate and amphibolite schist, though serpentine, ankerite, gabbro, diabase and diorite are also abundant. Throughout this entire belt the various mines have only a general similarity, no two being alike. In Mariposa and Tuolumne and southern Calaveras counties the veins are mostly found associated with black slate serpentine, ankerite and amphibolite schist. In central Calaveras county at and near Angels the veins are wholly in amphibolite schist. In northern Calaveras county, the Gwin mine is in black slate. The deep

mines near Jackson, Sutter Creek and Amador City are found in slates and amphibolite schist, and in northern Amador and southern El Dorado, slate predominates. About Placerville the veins of the lode resemble those of the central part of Tuolumne county.

THE fact that iron sulphide (pyrite) occurs in a rock is not good evidence that the rock containing it is not of volcanic or igneous origin. The argument that it would be impossible for pyrite to exist in a rock in a molten state is without weight. Pyrite is not considered an essential constituent of any igneous rock, but both iron and sulphur exist in any eruptive or volcanic rock when in a state of fusion, though of course not in combination as sulphide. Pyrite forms after cooling and is present in almost all intrusive rocks and some volcanic rocks. This pyrite rarely contains more than a trace of gold or silver, and often even traces are not obtainable by ordinary methods.

THE British Columbia law governing the relocation of quartz claims is as follows: The relocation of forfeited or abandoned quartz or lode claims shall only be made by sinking a new discovery shaft and fixing new boundaries in the same manner and to the same extent as is required in making a new location, or the relocater may sink the original discovery shaft 10 feet deeper than it was at the date of the commencement of such relocation, and shall erect new or make the old monuments the same as originally required. In either case a new location monument shall be erected and the location certificate shall state if the whole or any part of the new location is located as abandoned property.

CORUNDUM is divided into three classes: 1. Sapphire, which includes all corundums of whatever color that are transparent to semi-transparent. 2. Corundum, including the translucent to opaque varieties of all colors. 3. Emery, which is a mechanical admixture of corundum and magnetite or hematite. Corundum occurs in rocks of many kinds. The following occurrences of corundum are known in the United States: In peridotite; in biotite contact on saxonite; in eustatite; in serpentine; in chlorite; in amphibolite; in norite; in basic minette; in andesite; in amphibole-schist; in syenite, and in quartz schist. The greater number of localities are in the Eastern States, extending from New England and New York to Georgia. Corundum occurs in syenite in Gallatin county, Mont., 25 miles south of Belgrade. It also occurs in Plumas county, Cal.

THERE are two minerals mined and sold under the name of asbestos. One is a variety of amphibole, a silicate of calcium and magnesium; the other a variety of serpentine, known as crysotile, a hydrous silicate of magnesium. The latter is superior in the strength and elasticity of fiber, though each has about equal resistance to heat. Crysothile is usually greenish white to greenish yellow in color, of silky luster and composed of fibers easily separable. They seldom exceed 2½ inches in length. The fibers of the amphibole variety are sometimes 3 feet in length. They lack the silky luster of the crysotile, rather resembling flax in appearance. The fibers of the amphibole variety lie parallel with the schistose structure of the rock in which it occurs, and crysotile, occurring in small veins, lies at right angles to the strike of the vein. The only known deposits of merchantable crysotile are in Canada, Vermont, Wyoming and California.

THERE are two varieties of mica having a commercial importance—muscovite and phlogopite. The former is that most commonly seen, and is a constituent of many crystalline and sedimentary rocks. Its principal value is due to its occurrence in blocks or masses (called books) capable of being split into sheets a square inch or more in size, the value of which increases with increasing size. Although mica is a common rock constituent, the commercial deposits occur for most part in pegmatite dikes, sometimes called coarse granite. All of the minerals occurring in dikes of this character are of exceptionally coarse crystallization. Where the minerals of the dike occur in small masses the mica is also usually in small plates. A new use has been found for smaller sheets of mica which are cut into circular discs, from ¼ of an inch to 2 inches diameter, for use in electrical work as insulators. Small pieces of fine clear mica cut from large sheets are split very thin, rearranged and cemented together under heavy pressure, forming large sheets, which are then cut into desired shapes and sizes.

PYRITE and MARCASITE, iron sulphides, are usually distinguished by their differences of crystalline form, color, density and ease of oxidation. Pyrite usually crystallizes in cubic form, though often in complicated forms of the orthorhombic system. Sometimes the mineral assumes a massive or compact form without crystalline structure. Pseudomorphs are not uncommon. In color pyrite is described as brass yellow, while marcasite is tin white, grayish white, greenish brass yellow or bronze yellow. True colors can only be safely judged in fresh untarnished specimens. Tarnished specimens of marcasite when washed with warm dilute hydrochloric acid show a tin white or grayish white color, with no trace of yellow. To distinguish between pyrite and marcasite by color alone they must be washed with dilute hydrochloric acid and examined at once by good strong white light. Marcasite oxidizes more rapidly than pyrite under the same conditions, but a compact well crystallized specimen of marcasite can be kept a long time without other change than a slight tarnish; whereas finely divided or porous pyrite oxidizes with great rapidity, which fact has frequently caused pyrite to be mistaken for marcasite.

Use of Lime as an Alkaline Reagent in Cyaniding.

Written for the MINING AND SCIENTIFIC PRESS by
ERNEST GAYFORD.

In September, 1893, the writer, who was at that time on the technical staff of the Gold & Silver Extraction Co. of America, owners of the MacArthur-Forrest patents, was sent to Salt Lake City, Utah, as assistant to William Orr, F. I. C., the well-known metallurgist and chemist, who then represented that company in Utah, Idaho, Montana and Nevada.

The old Mercur G. M. & M. Co. were then lessees of the Gold & Silver Extraction Co., and their mill at Manning, Utah, was the largest under Mr. Orr's technical supervision.

The consumption of cyanide at this mill had risen to a somewhat alarming extent above the normal, and I was sent by Mr. Orr to Manning to ascertain the cause of this abnormal consumption and, if possible, overcome it.

After familiarizing myself with the ore, the plant, and the methods employed, I conducted the following tests:

No. 1—100 grams of the crushed ore were digested with 100 c.c. of a .1% KCy solution, without the addition of lime; KCy consumption = 1.5 pound per ton of ore. To another 100 grams of ore .25% lime was well mixed and mixture treated with same solution: KCy consumption = 0.6 pound per ton of ore.

No. 2—100 grams ore digested with .5% KCy solution to determine how much cyanide would be destroyed in the presence of an excess of cyanide (the working solution at the mill was kept at a standard of .075%); consumption = 2.2 pounds per ton. Cause of consumption determined quantitatively in the solution was found to be principally due to arsenious and arsenic acid compounds and aluminum salts.

No. 3— $\frac{1}{2}$ pound ore leached for twelve hours with .15% KCy solution, no lime, consumption = 1.4 pound; $\frac{1}{2}$ pound ore leached for twelve hours with .15% KCy solution, .1% lime, consumption = 0.9 pound; $\frac{1}{2}$ pound ore leached for twelve hours with .15% KCy solution, .25% lime, consumption = 0.4 pound; $\frac{1}{2}$ pound ore leached for twelve hours with .15% KCy solution, .5% lime, consumption = 0.3 pound.

No. 4—Free acid in the ore was found to be .0123%; latent acid in the ore was found to be .0157.

No. 5—1 pound ore agitated with 1 pound distilled water, digested for one hour, then filtered. To 100 c.c. of this filtrate was added 100 c.c. of a .5% KCy solution, allowed to stand, then titrated to determine loss due to soluble acids. Result showed no loss.

No. 6—A sample of the tailings as they were discharged from the tanks was taken to determine the amount of cyanide "held up" in them = 0.3 pound per ton. The following method was used for this: The percentage of moisture in the tailings was determined—say they were found to contain 20%; then weigh out 120 grams of tailings, place in a beaker, add 80 c.c. water, shake for a few minutes, filter, then titrate filtrate as in ordinary mill solutions; as the proportion of ore to solution (water) is 1—1, then whatever amount of cyanide was found in the solution indicated the loss per ton of ore—i. e., cyanide mechanically held up in the ore.

No. 7—No soluble sulphides were found in the mill solutions.

After reporting the results of my tests to Mr. Orr we decided that the results all pointed to the fact that the consumption was almost entirely due to basic acid salts, which could be partially neutralized by a judicious use of lime, which should have no detrimental effect on the per cent of gold extracted.

Upon investigating I found that on previous occasions lime had been added to the ore before it was put in the tanks, but no benefit was noticed from its use. Investigating further, I found that the method adopted in adding the lime was as follows: A certain amount—about 2 pounds to the ton of ore—of unslacked lime was thrown on the top of the pulp car previous to dumping it into the tank. Now, as the Mercur in those days was treating only oxidized ore and crushing very coarsely (to 1-inch mesh) it was very evident that in this method of adding the lime it was impossible for it to become thoroughly mixed with the ore, and therefore its use had never been given a fair trial.

We decided to dry slack our lime, screen it through a 6-mesh screen, and add it in small quantities at a stated rate per hour into the Gates crusher, with the ore, in this way giving it a chance to get mixed up in the revolving screen.

The daily capacity of the mill was about 300 tons and 400 pounds of cyanide were being used per day. We commenced by using 15 pounds of lime per running hour of the mill, and testing the solution frequently to catch any increase in its strength, while still using the same quantity of cyanide as had previously been added before using lime.

The lime was added a little at a time and considerable care taken to get it thoroughly mixed with the ore. During the day the writer added the lime into the crusher himself, leaving a weighed quantity to

be used by the night shift. At this time the strength of the solution used in the mill was kept as nearly as possible at 1.5 pound per ton. This was done by the addition of a certain quantity of fresh cyanide every hour to the "tail" of the zinc boxes, Mr. Orr having found by previous experiments that solutions of this strength gave the best average extraction, so that the point to be gained was to ascertain how little cyanide could be used and still keep the solution up to its working strength.

The solution was carefully and frequently sampled on the two days preceding the use of lime, and its strength was found to be 1.7 pound and 1.8 pound KCy per ton, using 400 pounds of cyanide per day.

On September 18th 250 pounds of lime were used to 316 tons of ore, and on the 19th 336 pounds of lime were used to 290 tons of ore. On this day it will be seen by the table below that the strength of the solution had risen to 2.06 pounds per ton, and the quantity of cyanide per day was reduced by 50 pounds.

The strength of the solution still kept increasing and on the 21st another 50 pounds was knocked off; on the 22d 12 $\frac{1}{2}$ pounds, and on the 23d 12 $\frac{1}{2}$ pounds more, and the lime was increased.

From the table it will be seen that between September 20th and October 13th the amount of cyanide being used per day had been reduced by 196 pounds, and 4 pounds of lime per ton of ore were being used.

At this point we found we had gone as far as was feasible, as any further increase in lime did not increase the strength of the solution sufficiently to compensate for the consumption of cyanide that took place in the zinc boxes due to an excess of alkali in the solution.

DETAIL OF THE USE OF LIME AT MERCUR MILL, MANNING, SEPTEMBER, 1893.

Notes on Assaying.

TO THE EDITOR:—The use of borax, fully hydrated, or even partially so, in the body of the charge, for fluxing purposes in assaying, cannot be too strongly condemned. Its use, however, as a cover for the charge is to be recommended. For this purpose the crude article, or borax of a high degree of hydration, is superior to the anhydrous borax or borax-glass. Used in this manner it swells and curls above the charge at a very low temperature, forming an impervious cover or roof through which spouting can not occur; and as the melt progresses the then fused borax sinks into the charge ready to perform its function as a flux.

In regard to the use of hydrated sodium bicarbonate, this must be regulated by the individual requirements of different ores. But aside from a consideration of the chemical reactions merely, between the ore and fluxes during fusion, it is necessary to have a certain looseness and tumbling about of the charge to obtain a proper contact and settling of the lead containing the precious metals. If anhydrous fluxes alone are used there is but little boiling, the charge is pasty and the reduced lead sinks through it only after prolonged heating at a very high temperature.

The evil resulting from "dusting," which is caused by the production of a large volume of gas or vapor, is entirely obviated by the use of a crude-borax cover, as above noted, but as this condition is more often due to the presence of carbon or sulphur than to hydrogen, the argument against hydrated fluxes, because of dusting, is without effect.

Prescott, Arizona, Dec. 20. A. D. BARNHART.

Experiences of a Working Miner.

Written for the MINING AND SCIENTIFIC PRESS.

Mining requires enterprise, energy and courage, and incidentally money—one's own or other people's. There are many who have all of the former qualities when backed by the latter. P— of S— B— had all of the former in abundance, but was woefully deficient financially. This, however, did not daunt him in the least. He happened to know of a gold mine on the Mojave desert, in California, and knew that this mine contained considerable value, but not enough to pay expenses. The property was worked through tunnels, and was equipped with a mill. This was fortunate, for he would have been unable to have provided a mill. P— hired a four-horse team and wagon, loaded it with tools, supplies, provision and men—all on credit, herein showing his courage—and proceeded to the lonely desert mine, which, by the way, he did not own, had not leased nor bargained for—evidencing his enterprise—and upon arrival at his destination set the men to work making preparations to start up. This was soon accomplished. Wood and water were hauled, ore broken in the mine and the bins in the mill were soon filled. This showed his energy. The stamps were dropping inside of a week and for three weeks things ran smoothly, a goodly amount of amalgam being collected. This having been successfully accomplished, P— took the cleanup and vanished into the desert distance, proving his possession of another quality not previously mentioned—discretion—for the sheriff had been in some manner made acquainted with P—'s enterprise, and went out across the desert to interview him, but P— reached the railroad first by forty-eight hours and has not been heard from since. This was the first and only time that the H— mine on Dry Lake had ever been known to pay a dividend.

**

The M— mine at L— was a new enterprise. A vertical shaft had been sunk 400 feet and a new hoisting engine put in. The machinery was all in place and everything was ready to run. Four men were at work in the bottom of the shaft. A skip was sent down and was filled with rock at the bottom. A single bell gave the signal to hoist. The engineer carefully and slowly started the load, brought it up into the head frame and dumped it. Here he should have made side marks on his reel, to show exactly the point where the engine should be stopped, but this precaution was neglected. The skip was lowered for a second load and in a few minutes again came the single bell—to hoist. Once more the engineer cautiously pulled the throttle and the load was hoisted and dumped without incident. A third time the skip was sent down into the deep, black shaft for its cargo of rock. Once more the signal bell. The superintendent stepped to the levers and with firm and confident hand started the skip from the bottom. All went well, and the load in time came to the collar of the shaft. The "super" still grasped the throttle and brake levers, and with keen eye fixed on the indicator, about 12 feet distant, continued to hoist. The skip wheels ran forward onto the horizontal track and the lower end slowly lifted and overturned. At this point had the "super" shut off steam all would have been well, but he thought the index did not quite cover the mark on the indicator and hoisted a little farther. He overwound about 18 inches and with a crash and roar nearly half the skip load of rock fell into the shaft—and four helpless miners below, in blissful ignorance of what was happening on the surface, with no sheltering drift to dart into.

The "super" looked white and we all held our breath—consternation on every face. An auxiliary engine was still in place at one side, and the foreman was slowly lowered into the shaft. He had good nerve and was prepared for a terrible sight at the bottom of the shaft. He reached the bottom and after several minutes came the signal 3—1 (hoist men). Ever so slowly the bucket was hoisted with the entire grimy, mud-bespattered crew. But the pallor of their faces could be plainly seen through the dirt. Not a man injured—a miracle. Only a small quantity of the rock reached the bottom of the shaft, the greater portion falling upon the timbers. "All's well that ends well," and the entire incident illustrates clearly the necessity for employing common sense about a mine, particularly where the lives of men is a consideration. No one should attempt to run automatically dumping rock carriers without side marks on the hoisting reel. The indicator is useful only to give general knowledge of the position of the skip in the shaft, and should not be depended upon for exact placing of the skip at levels or elsewhere in the shaft or at the surface.

THE fact that an ore deposit does not go down should not condemn it, if the deposit is large enough and rich enough to pay a good profit as long as it lasts. It has the advantage, at least, of indicating to the miner when to stop expenses in a useless search for more ore.

The Mining Industry of the Cœur d'Alenes, Idaho.*

By J. R. FINLAY, Colorado Springs, Colo.

GENERAL DESCRIPTION.—Of the Cœur d'Alene silver-lead mining district of northern Idaho, so far as the writer is aware, little has been written, and little is known about its geology and resources. People interested in lead-smelting are, of course, cognizant of the economic importance of the region, but they have not communicated much of their knowledge to the public.

Exact figures as to the total output of the district

1901 the product was about 150,000 tons of concentrates, with a gross value of \$8,250,000.

The central point of the district is the town of Wallace. The main feature of the topography is the low range locally termed the Cœur d'Alene mountains, which are the northern extremity of the Bitter Root range. The highest summits in the neighborhood of the mines scarcely exceed 6000 feet in altitude. The mountains are the remnants of a deeply eroded broad plateau. The veins have been found outcropping at altitudes varying from 2400 feet at the extreme west to 6000 feet at the eastern and northern extremities. The country was once covered with a dense forest of fir, pine, cedar and tamarack. Near the mines a good deal of the original forest has been destroyed by fire or axe; but everywhere a new

dike on the ridge between Canyon and Nine Mile creeks. This mass has produced a well-marked contact metamorphism in the slates and greywackes which surround it, and has exercised an important influence on the vein formation of its neighborhood. The important mines on Canyon creek are all within a mile of it; and silver-lead veins of more or less value occur at intervals along its whole periphery and even within its borders.

At a number of places there are basic dikes, usually narrow, producing little or no metamorphism in the sedimentary rocks, dark green in color, heavy and unaltered. In some cases they cut through the lead-bearing fissures, with no effect whatever on the values or the mineralization of the veins. But in one important instance the Hecla vein follows a narrow

Fig. 1—Sketch Showing Relation of Sierra Nevada and Bunker Hill Lodes.

Fig. 2—Plan Showing Course of Sierra Nevada Vein.

Fig. 4—Mammoth-Standard Vein Showing Fault.

Fig. 6—Structure Mammoth-Standard Vein.

Fig. 3—Showing Outcrop Bunker Hill Vein.

Fig. 5—Workings Sierra Nevada Mine.

are not obtainable, but the following estimates, covering the entire output of the fifteen years during which the mines have been operated, are believed to be approximately correct:

Group of Mines.	Product.
Wardner Group, including the Bunker Hill and Sullivan, Empire State-Idaho, Last Chance, Sierra Nevada, Cœur d'Alene Development Co.....	\$17,500,000
Canyon Creek Group, including the Gem, Frisco Consolidated, Granite, Standard, Hecla, Tiger-Poorman, Custer and Bell...	35,000,000
Mullan Group, including the Morning, You Like and Gold Hunter.....	7,500,000
	\$60,000,000

This output covers the period of discovery and early struggles, and several periods of stagnation caused by strikes and other serious labor troubles. In 1900 the output of the district was fully \$10,000,000, and this figure would have been considerably increased in 1901, had not a curtailment of production been forced by the condition of the lead market. In

growth keeps the hills green.

The geology of the Cœur d'Alenes has never been thoroughly studied and practically no details of it can be given. A vast formation of slates, greywackes and quartzites, thrown into east and west folds, covers the entire region. These rocks are all fine grained, no conglomerates or even moderately coarse sandstones being seen anywhere. True vitreous quartzites are rare. The rocks in which the lead-bearing veins occur are usually light colored and could be best described as fine-grained greywacke, or something between slate and quartzite. There is only a mild regional metamorphism. As a rule, very little formation of new minerals has taken place in the rocks. They are generally banded, though the stratification is often obscured by dynamic action. Rarely, however, is there a well-developed cleavage. The movements in the rocks have only produced a strong jointing in a direction usually parallel to the neighboring fissure veins. This jointing is so pronounced in places as to give a schistose character to the rocks.

Igneous intrusions are rare. Only two kinds have been observed. The most important is a syenite or quartzless granite, which makes an enormous boss or

dike for its entire length. The mineralization has taken place along the walls of the dike and in many places the basalt seems to have been, to some extent, actually replaced by galena.

VEINS AND ORE DEPOSITS.—All the ores of the region come from fissure veins, in which argentiferous galena is associated with large quantities of siderite. The fissures occupy fault planes, on which the amount of movement is indeterminate, but probably in some cases considerable. The fissure is usually well marked by a streak of gouge, between walls which are slickensided and often beautifully polished. As a rule only one principal plane of fissuring can be found in each vein. This is very apt to occur near the middle of the vein, but often forms one wall of the lode. Two defined walls, marked by planes of movement, are extremely uncommon.

The principal minerals of the lead-bearing lodes are quartz, siderite, galena, zincblende and pyrite. Near the surface oxidation has produced lead carbonates, iron oxides, manganese oxides and native silver.

The minerals in some veins are scattered somewhat indiscriminately through the mineralized zone;

*Trans. Am. Inst. Min. Eng.

but they are more apt to be arranged in streaks or zones parallel to the master fissure. It is noticeable that, along the actual fissure plane, the galena and other minerals are nearly always fine grained, while at some distance from it they are apt to be much coarser.

In some veins the minerals are found to be well segregated in individual streaks, the argentiferous galena, for instance, forming seams containing from 60% to 80% of lead. In other veins, or even in other parts of the same vein, the various minerals are intimately mixed in the same ore streak, greatly diminishing its value. In different mines, and even in the same mine, the proportion of silver in the galena varies greatly, say, from 0.25 ounce to 2 ounces of silver to 1% of lead.

The ore bodies occur in every conceivable position, from horizontal to vertical. Some of them are large, containing millions of tons of concentrating ore. Three of the most valuable deposits in the district do not reach the surface at all, their apexes lying several hundred feet below it. Two of these are and the third is not below the limits of oxidation. It does not appear that leaching by surface waters has in many cases destroyed the lead values, but there are instances where this has happened. The workable deposits, as mined, carry from 5% to 25% of lead. The average values for the district are perhaps 10% lead and seven ounces silver per ton.

THE BUNKER HILL LODE.—This fissure differs notably from the other veins of the Cœur d'Alenes. It seems to be the sole source of the ore in the Wardner district. For 6000 feet from the eastern end of the workings of the Bunker Hill and Sullivan to the Viola claim of the Empire State-Idaho, the workings are continuous. From the Viola northwestward to the Crown Point the continuity of the fissure is not so clearly established; but all the ore that has been found follows the same extended line, and the workings on the Silver King and Crown Point display a fissure with the same dip, strike and general characteristics as in the Bunker Hill.

All the mineralization has taken place on the hanging wall side of the fissure, which therefore forms the foot wall of the lode. A white "gouge" of thoroughly crushed and altered rock lies upon the unchanged quartzite of the foot wall. Lying upon this white gouge is a strongly mineralized zone, which begins with a streak of bluish or black gouge containing galena, always very fine grained. The lamination of the rocks parallel to the fissure plane is strongly marked for only a moderate distance (from 5 to 50 feet) from it; but within this zone of parallel lamination the minerals, valuable or otherwise, are invariably fine grained. The lamination in this foot wall zone has reduced the rock to the condition of gouge material only for a foot or two next the foot wall.

Passing outward from the fissure, the mineralization extends far into the hanging wall, which has undergone much fracturing. For from 100 to 300 feet from the fissure the joints and seams in the quartzite are apt to be filled with galena, with subsidiary quartz and iron carbonate. Farther from the foot wall the quartz, siderite and pyrite predominate, to the final exclusion of the galena.

The quartz, siderite and pyrite in their turn diminish in amount until at, usually, not more than 400 feet from the foot wall, all mineralization has disappeared, and the quartzite of the hanging wall resumes the appearance of the foot wall quartzite.

The workable ore bodies in the Bunker Hill lode are simply those portions which contain enough galena to pay for working. Ordinarily such bodies lie partly in the laminated zone next to the foot wall or fissure, and partly in the fractured rock in immediate contact with this zone, on the hanging wall. In almost every case ore bodies appearing in some places to be at a considerable distance from the foot wall have been found, when followed up, to connect with it. There are, however, three conspicuous ore bodies, the "workable" connection of which with the foot wall has never been established. Two of these (the Curtis-Hatton body in the Bunker Hill and the hanging wall stopes in the Last Chance claim) seem to follow channels made in some way by the fracturing of the hanging wall in a course essentially parallel to the foot wall, but at some distance from it; and the third, the Sierra Nevada deposit, is a unique occurrence, which merits a more extended description.

As a general fact, however, it may be declared that the main foot wall fissure was the source of all the mineral deposition along the lode; that the ore-bearing solutions have enriched portions of the hanging wall country wherever a favorable channel existed, and that these channels may have been cross fractures or local branch fissures, regions of extensive crevice openings due to jointing, or openings along the bedding planes of the rocks.

THE SIERRA NEVADA LODE.—This is a peculiar and highly specialized example of a branch vein. It is a fissure with the shape of a broad anticline which dips gently southwest, nearly at right angles to the strike of the great fissure. The actual intersection of this anticlinal deposit with the fissure has been destroyed by the erosion of Deadwood gulch, but the deposit obeys in a general way the rule governing the other deposits along the Bunker Hill lode. From a point on the surface on the crest of the anticline

nearest the line of the main fissure it slopes gently away down the crest and sides of the anticline, and, as it does so, it loses its ore, becomes more quartzose and ferruginous until, as in other deposits, nothing remains in it but quartz and iron.

This remarkable deposit, covering an area of six acres, has been worked out. The old mine levels show the contours of the anticline. The ore was all oxidized, rich in silver, and from 6 inches to 6 feet thick.

THE CANYON CREEK LODES.—These are very different from the Bunker Hill. The fissures are much smaller, simpler, and more uniform. They are nearly vertical, rarely dipping less than 75° north or south.

THE MAMMOTH-STANDARD VEIN.—This important lode has produced lead and silver of the gross value of about \$11,000,000, yielding at least \$3,000,000 in dividends. It has been traced from the west end-line of the Mammoth claim eastward to about 900 feet east of the line between the Mammoth and the Standard, at which point it has been cut off by a considerable fault, and the continuation has not yet been found. The lode has proved productive for a length of 2400 feet; and, by a curious coincidence, its richness seems to increase until its abrupt termination by the fault-plane above mentioned. (See Fig. 4.)

The fissure strikes north 65° west and dips 77° north. The quartzites along the fissure dip west at a moderate angle, so that the vein cuts the formation nearly at right angles.

The fissure is a fault of moderate displacement. A well-defined plane of movement can always be found in the vein, sometimes on one side, sometimes on the other, and often in the middle. As in the Bunker Hill lode, the ore immediately next the fissure shows a finer grain than that deposited farther away. Fig. 6 shows the arrangement of the ore bodies on the Standard and Mammoth, as developed on the Campbell tunnel level.

In the Standard mine, the vein has always two, and often three or more, well marked ore streaks; but west of the Standard ore shoot there is seldom or never more than a single streak.

The ore body mined on the Standard varies from 5 feet to 50 feet, and averages about 17 feet in width. There are no defined lode walls, the fissure invariably lying within the mineralized zone, and the mineralization having affected the sheared rocks on either side. As a general rule the rock on each side of the ore body is sheared and crushed for 3 feet or more from the outermost ore streaks to such a degree as to render the ground loose and unstable. Beyond the limit of the sheared zone the country rock is firm and unaltered except where it is affected by transverse faults. The parallel zones of sheared rock on each side of the ore make the walls very heavy and practically impossible to hold by timbering.

THE FRISCO LODE.—This deposit has been disturbed by a number of cross faults. The fissure proper is nowhere well marked, but the whole mass is firmly cemented together and the mineral is "frozen" to the walls.

(TO BE CONTINUED.)

Seeking Increased Water Supply.

The demand for a constant and abundant supply of pure water is continually increasing in large cities and in some of them the problem has become one of paramount importance. This is notably the case with New York City. Twenty years ago the old Croton aqueduct supplied all demands, but the foresight of the city's engineers resulted in the construction of the new Croton aqueduct. Now, it is seen that ere many years this will afford an insufficient supply. The United States Geological Survey has taken up this matter and water supply paper number 76, of the Survey, now in press, consists, in the main, of technical "Observations upon the Flow of Rivers in the Vicinity of New York City," by P. A. Pressey. The measurements of the rivers discussed in this paper were started at the suggestion of G. A. Birdsall, chief engineer bureau of water supply, New York City, in order that data might be available for investigations as to additional water supply for New York City.

In considering the future demands of the city of New York for water, Lake George, Lake Champlain, the Great Lakes, and the Hudson river have been suggested. It has been found that the supply from Lake George would not be adequate; that Lake Champlain is at too low an elevation for economical use; and that the supply from the Great Lakes would entail great and unnecessary expense. The water from the Hudson river might be taken near its headwaters and conducted to New York City by a long aqueduct, or the intake might be located just above Poughkeepsie, which would necessitate pumping and filtering before delivery at the city.

In the summer of 1901 a reconnaissance was made of Catskill river and Esopus creek, Wallkill river and Rondout creek, west of the Hudson, and of Fishkill creek, Ten Mile river, and Housatonic river, east of the Hudson.

Nearly the entire length of each stream was traversed, and a site for a gauging station selected for each. The results of the measurements have been published in water supply paper No. 65.

Motions of Underground Waters.

The amount of water within the crust of the earth, says Prof. C. S. Slichter, in a paper entitled "The Motion of Underground Waters," recently published by the U. S. Geological Survey, "is enormous, amounting to 565,000 million million cubic yards." His estimate is based upon the supposition that the average depth which waters can penetrate beneath the surface is 6 miles below the land and 5 miles below the ocean floor. This vast accumulation, if placed upon the earth, would cover its entire surface to a uniform depth of from 3000 to 3500 feet. Under the influence of gravitation, the water is generally in motion, and the object of Prof. Slichter's paper is to describe the rate and manner of its overflow and the laws governing the same. Experiments have shown that not only do sands and gravels possess porosity, but rocks, presumably solid and compact, may be traversed by water. Even so hard a rock as Montello granite, selected for the sarcophagus of the tomb of General Grant on account of its great strength, shows a porosity of 0.23%. The most productive water-bearing rocks, however, are found to be the porous sandstones, and, in some cases, limestones, whose inner texture has been chemically dissolved.

The popular idea of underground waters is derived from the rivers of copious discharge found in the Mammoth and other caves. But this idea is erroneous, as such streams, though of great local importance, are comparatively rare. The great mass of ground water slowly percolates through sand and gravel deposits, sandstone and other porous material under a wide extent of territory. Though its motion carries it but a fraction of a mile in a year, this ground water is so widespread and often so accessible as to be of the greatest economic importance.

The rate of movement of the underflow has been the subject of long and careful investigation. To determine this interesting question, measurements have been made in the river gravels of streams whose surface flows have ceased, and from such measurements more or less trustworthy results have been obtained. One of the most accurate and interesting of these is a series of experiments conducted by Prof. Slichter along the valley of the Arkansas river in western Kansas. The method is an electrical one. A double row of 1½-inch drive wells is sunk across the channel of the river whose underflow is to be tested. The upstream wells are then charged with a strong electrolyte, which dissolves and passes down the stream with the moving water. The passage of the electrolyte toward the lower well is shown by a sudden and strong deflection of the needle. It is exceedingly interesting to watch the gradual movement of the water, which can be traced from the beginning of the experiment in this indirect way. By this method the rate of flow 10 feet below the bed of the Arkansas river was found to be 2½ feet per day. Other experiments in the beds of the Hondo and San Gabriel rivers, in southern California, gave rates of 3½, 4, 5½ and 7 feet per day.

The knowledge of the underflow that exists beneath the gravel of all river valleys has been taken advantage of in arid sections of the West, where the running dry of streams deprives irrigators of their water supply. By excavating to bedrock in river gravels and building an impervious barrier across the channel, these underground waters are saved in sufficient quantities to be of great value to the farmer. A notable subsurface dam of this kind has been constructed on the Pacoima creek, Cal., to furnish water for irrigation and domestic use.

New Uses for Slag.

The utilization of the slag from furnaces, after long discussion, has passed the experimental, and reached the profitable, practical stage, says Cement and Slate. Its reduction to a granulated substance has opened a wide field for its use in various arts. As a vitreous sand, it is made into bricks by mixing with a suitable cement, and, mingled with lime, it makes a good mortar. The bricks are pressed and sun-dried at a cost 25% less than common bricks, and as they are white, they are quite popular with builders. The sand, scattered on unburned clay bricks, gives them an enameled face when hurned, and, by mixing with fire clay, an exceedingly refractory firebrick is produced. By various other processes, this useful sandy product is made into cement, shingle for road-heds, brick dust for flooring, and for hedding in which to run hot metal in making pig iron. It has been also used for ballasting railroads, and for ships' ballast; but the demand for slag bricks is so good that it is thought these two markets will soon be denied. The most common way of treating the slag is to run it from the furnace into a powerful stream of water that falls into a tank. The velocity of the water carries the sand into the tank, and the water flowing under the molten metal is partly converted into steam that materially aids in shattering and disintegrating it. From the tank, the sand is raised by means of an elevator, and the whole apparatus only demands the attendance of two boys to keep it stirred in the tank, and power to move the elevator.

An Experience in Drift Mining in Hard Cement Gravel.

Written for the MINING AND SCIENTIFIC PRESS by L. H. CARVER.

Believing that the exchange of ideas, opinions, and actual experiences while engaged in the every-day work about a mine, through the medium of a paper like the MINING AND SCIENTIFIC PRESS, presents one of the very best means for the dissemination of useful knowledge, the writer will take advantage of the opportunity thus afforded to describe as briefly as

possible the methods employed by him in superintending the operation of a drift mine in Calaveras county, Cal., with the hope that some benefit may be derived therefrom by those who are engaged in similar operations elsewhere, in which event the satisfaction of knowing that he has in a measure contributed to their success, will amply justify the effort.

The mine in question is located on the old Fort Mountain channel, an ancient channel traversing the county in a general north and south direction, as shown in the accompanying map, and is opened by a

vertical shaft sunk on the edge of a ravine, the depth at this point being 55 feet, where it encountered bedrock on the west rim of the channel.

From the shaft, levels are run up and down the channels, with air shafts at each extremity, the south shaft at the down-stream end of the ground being provided with a pump for handling the water at this end of the mine. (See Fig. 1)

Drifts are run from the main gangways or levels, across the channels at regular intervals in the usual manner, and the gravel breasted out and removed in cars to the shaft, where a bin or pocket has been constructed to expedite hoisting, and enable carmen to deliver gravel and return without delay.

The previous method in vogue here required the use of wheelbarrows in moving gravel from the breasts, boulders being allowed to remain in the drifts, and planks laid over them for a runway to the main gangway, where the material was dumped on platforms and shoveled into cars, a slow and laborious method, often attended by annoying accidents in transporting the material over the narrow and insecure footway. There being no receptacle at the shaft for the storage of gravel, the carmen were compelled to wait for the bucket, and it frequently happened that cars would arrive simultaneously, from both sides, one being compelled to wait for the return of the bucket, after the other had dumped its load and signalled to hoist.

A great deal of time was thus lost that could have been more profitably employed in storing boulders and other work, after the gravel from that particular breast had been removed.

This system was immediately changed and switches and tracks laid in the drifts, being subsequently removed as the breasts were carried forward; the sump was cleaned out and a bin constructed enabling cars to make a round trip without delay, and the water bucket was replaced with a pump, removing another source of vexatious delay, when it was required to hoist water, instead of gravel, and the bin on top was about empty.

The gravel is a hard blue cement, with cobbles and boulders varying in size from hen's eggs to rocks that must be broken up before moving, although but few of the latter were encountered, the majority being readily handled.

We were informed that it would be impossible to work the mine "on account of the boulders," and that "one-half the time was required hoisting rocks," but that the gravel was good, but "about in the proportion of mortar in a brick wall," and many other discouraging aspersions. The reason for so much time being occupied in hoisting boulders under the old regime was soon discovered—large chambers being walled up along the gangway—an old trick—and to all appearances, at first sight, a solid mass.

Behind the wall, however, where rocks should have been stored from bedrock to roof, was nothing but space, and throughout the old workings the boulders

were not built up to the roof, in places sufficient space being found to enable one to crawl in over them, all of which space, however, was utilized later for its proper purpose.

From the character of the ground, the use of hammer drills was discontinued, for the reason that too many holes were lost by coming into contact with rocks, the size of which was uncertain, and after considerable labor in trying to get through or break one of these hard rocks, unsuccessfully, it would frequently be necessary to start a new hole.

As a substitute for drills, the "gopher bar" was used with marked success, as with this tool a hole can be easily turned aside a little, until the size of the rock has been determined, when the drill can be used, either to break or work through it, and in many cases it will be possible, by a slight deflection, to continue the hole past the obstruction without resorting to the slower method of the drill.

Drifts were laid out crosscutting the channel at regular intervals of about 60 feet, that being the most economical length of breast for the accommodation of two miners, and for handling material, requiring less track work and moving of platforms.

Beginning at the center, after the end connection between drifts is run, forming a rectangular block of ground, the miner works to the drift and back to the center, breaking out the gravel, separating the boulders, and throwing the milling dirt on the platform, ready for the car man, who also when loading his car removes as far as possible the large cobbles and sends up only such material as will pass the grizzly.

The occasional larger pieces remaining on the grizzly are broken up or removed by an attendant when the opportunity offers.

It was found advisable, owing to the distribution of the gold, to work out the gravel to a height of 5 or 6 feet—a very comfortable height for men to work; bedrock is cleaned as the breast advances, and all rocks are piled back and built up compactly to the roof, an occasional post and cap being used when the roof shows any signs of weakness; but, by keeping the rocks well built up, the use of timber can be reduced to a minimum.

Of course, conditions will vary, but in this case no trouble was experienced in supporting the roof, which was found to be exceptionally favorable, it is true, and less than 100 feet, linear measurement, of posts were required for an entire season's work.

In passing, it will be in order to say that careful consideration and study should be given to the plan of underground development, and the conditions under which the work is to be carried on and all details in connection therewith laid out in accordance with a prearranged system, both as to the method of running drifts and opening breasts, and also in handling material, the main object being to accomplish the latter with the utmost expedition and with the least amount of dead work—in other words, with the greatest economy.

Each shift, when beginning work, cleans up the dirt and removes the boulders thrown down by the last round of blasts fired by the previous shift upon quitting work, and puts in a round of holes to be fired just before luncheon, during which time the mine will be thoroughly ventilated and the obnoxious fumes of the powder entirely removed; the last half of the shift is similarly employed, the blasts being fired upon leaving the mine.

The kind of powder used was the No. 2, 40% nitro, which was found to be more satisfactory generally, and while black powder in this kind of ground seems to shatter and break up the cement a little more, the convenience of handling the first named finally decided us in its favor.

It is of the utmost importance that all details of the work be arranged systematically, for upon the proper performance of the same depends, in a great measure, the degree of success attained, the other elements of success being the presence of gold in paying quantities, and adequate means for saving it, which will be described in another article.

Without a system the running of the mine becomes a sort of go-as-you-please, haphazard affair, that is rarely successful from the investor's standpoint; therefore, we reiterate, study the conditions carefully, perfect the system, select a foreman who can carry out the arrangement, and you will accomplish the best results.

(TO BE CONTINUED.)

Raising a Smokestack.

I had the job to raise a stack 40 inches in diameter and 90 feet long, writes a correspondent in the Wood Worker. As the work was done with nothing but a set of 3/4-inch blocks and a barely sufficient amount of rope, the details may be of sufficient interest to others similarly situated.

The stack, with the wire guy lines attached and all swung clear of the ground, weighed 2200 pounds, and had to be raised to the top of the boilers and breeching, at a point 15 feet above the ground level. This made a total height for the top of the stack of 105 feet.

The first thing to be done was to get a gin-pole for the stack, and as we were in a pine forest, it would seem an easy matter. But trees that will make good sawlogs will not make a gin-pole, for those that

Map of a Portion of Calaveras County, Cal., Showing Fort Mountain Channel.

are straight enough are liable to be too heavy, so we were nearly a mile from the mill when we found a tree straight and slender and of the right height.

The length of the gin-pole needed for this particular job was 66 feet net. Taking half the length of the stack, 45 feet, and add 2 feet for the overbalance, makes 47 feet. To this must be added the height to the top of breeching, 15 feet, making 62 feet. To this add 4 feet for block and rope clearance, making a net length of 66 feet. This length will cause the cry of "two blocks" just before you are in a position to slip the stack on the breeching, so it is best to add 4 feet as a factor of safety, making the pole 70 feet long. This we did, cutting the stick 70 feet from the straight end of the top, as far up among the limbs as it was deemed prudent, leaving the heavy butt at the stump.

Next thing to get was a jack-pole to raise the gin-pole, and following the same line of calculating, it took 35 feet for half the pole, 2 feet for balancing, and 6 feet for clearance, making 43 feet for the jack-pole. This was easily obtained near the larger pole, and when the two were brought together it was a fair load for an ox team. But we were miles away from the camp of loggers and it would take two days to get a team; meantime work was waiting on that stack.

One of the mill "dollies," or rollers, was dragged out to the poles, and turning the dolly over, the two poles were lashed to it at a quarter of their length. With the tackle and 500 feet of line, long hitches were taken from tree to tree, and the two poles ridden into camp in three hours, over a space of a mile, up and down hill and around curves.

Arriving at the mill, it was the work of but two hours to get the poles up and the stack in place, when the raising was accomplished with a windlass made of a piece of one of the poles set between two trees, turned by handspikes, and in seven hours from the time the poles were cut a mile distant from the mill, the stack was up and the guys fastened. Be dead sure your guy ropes are long enough; if not, you are very apt to drop the stack before it is in place.

The Kinkead Mill.

Herewith is illustrated a portion of the Kinkead mill. Concerning the improved Kinkead mill, the manufacturers say that on the Comstock, under the inventor's direction, "it has been crushing practically the entire output of the Con. Virginia mine." It is now placed on the market by Henshaw, Bulkley & Co., who have the rights for the continent of North America, including Mexico and Alaska. The princi-

chrome steel shoes bolted thereto. The inventor claims for the mill economy of power, and that about 2½ H. P. will run the mill at 150 revolutions per minute on hard quartz, crushing from ten to twenty tons per twenty-four hours, according to screens used, friction being reduced to a minimum, as pounding or hammering are impossible, and the large screen surface (6 square feet) and its continuous discharge permits the pulp to leave the pan as soon as it has reached the desired fineness. The manufacturers say: "The shoes and dies wear with surprising equality and evenness, and will last over a year. The peculiar movement of the mill scours the free gold and renders it more susceptible to amalgamation. In addition, the weight of the mill (6500 pounds), and the fact that it runs without any other foundation than ordinary mudsills, makes it a device that can be easily and cheaply installed anywhere." The heaviest single piece weighs but 1900 pounds. The mill is on exhibition at Henshaw, Bulkley & Co., Cor. Fremont and Missions Sts., San Francisco, Cal.

Economical Mining Method Required.

TO THE EDITOR:—Under the above heading a Colorado correspondent asks for information as to the cheapest way of extracting ore by stoping from a vein that caves readily and which is too low grade to afford the using of timbers.

It is well to bear in mind that many ledges are being worked which could not be made to pay if timbers, and labor as well, were given free of cost.

The cost of timbering rarely exceeds \$1.50 per ton and falls as low as 10 cents for timber used to each ton of ore extracted. This is figuring lumber at \$20 per M.

Every miner of experience knows that nothing equals broken rock and earth for filling up the cavity made in a vein after the ore is extracted; but in order to work economically by the filling system alone certain natural advantages must exist in the particular mine that is to be worked, and a system must be pre-arranged in order to work it properly along this line. The vein must stand sufficiently vertical to allow the filling between walls to drop by gravity from level to level. The walls should not be extra hard nor the vein filling very soft.

A flat vein is very expensive to work by this system. The flat "contacts" of Leadville, Colorado, for instance, are timbered with square sets on the Comstock, Nevada, plan, and could not be worked successfully in any other way. On the contrary, the Silver Lake mines, near Silverton, and the Revenue Tunnel properties, near Ouray, in the San Juan district, Colorado, are nearly vertical veins from 8 to 20 feet in width between walls; both these properties are situated at a high altitude, being above timber line, and as timbers must be carried up hill many thousands of feet, as little of it as possible is used. Nevertheless it has not been found possible, nor considered advisable, to even try to dispense with timbers altogether. The main gangways are securely and heavily timbered, chutes are put in about 30 feet apart and made of 8-inch round cribbing 4x4 feet in the clear and carried up as stoping proceeds. The filling material is secured by blasting down the walls and by crosscutting them where necessary; the main object which is always kept in view is to keep the stopes filled to within 5 or 6 feet of the roof; this is a very important though frequently overlooked point.

If your miners are compelled to erect a high and often unstable staging to get at their work of drilling the roof, half their time or more will be wasted in "sounding" loose slabs and watching for caves. To get your money's worth in labor from your miners they must be made to feel that some one competent to know is looking after their personal safety. Divested of all sentiment, it pays returns in dollars. No man with the proper stuff in him will compel another to work in a place too dangerous for himself. It has been said that a mine which will not pay to timber will not pay a dividend, and as a rule it is true, for the preliminary expense connected with putting a mine in shape to work without timbers often costs more than timbering. Many large mines have surface quarries and make expensive chutes from them into the ore stopes below; this is not always done to save timbering, nor as a matter of economy; it is often a matter of necessity and done to hold up ground, already timbered, which is beginning to weaken. A cheap method of working one mine may be a dear one in another. We have to come back to the axiom, "Each mine is a problem

unto itself;" there is no hard and fast rule which applies to the working of all mines alike. A certain amount of inventive ability is required in the mental makeup of any mine worker; difficulties present themselves from day to day which must be overcome, and quickly, but life is too short to be continually trying new experiments in the face of the fact that the mill or smelter must be kept going, that the board of directors growl at the expense, and forgive no mistakes, and the clamor of stockholders for dividends must be appeased. This is where experience comes in, and a knowledge of the successes and mistakes made by ourselves and others in the past is of more benefit than our gilded, untried plans, our hopes or our wishes.

Sonora, Cal., Dec. 24.

CHAS. L. LANG.

A Study of Amalgamation Methods, With the Object of Avoiding the Loss of Mercury.*

NUMBER III.

By MICHAEL BUSTAMANTE, JR., M. E., City of Mexico.

The exact estimate of the quantity of sulphate of copper to be employed is of great importance. If too little is added, the treatment is checked; the sulphate is converted into suboxide of copper; and the mercury, floured and oxidized, cannot be easily recovered by washing the torta without some injurious change in the compounds of silver.

If, on the other hand, the sulphate be in excess, the chloride reactions are very energetic, the mercury being rapidly converted into chloride (with liberation of 62.8 calories of heat); whereas, the formation of silver chloride (liberation only 29.2 calories) cannot take place. By subsequent reactions and outside influences, among which are the admitted effects of light and organic matter, a portion of the mercury is converted into an oxide, which is, like calomel, almost insoluble in the more or less concentrated solution of salt to which the principal reactions of the patio process are ascribed. A considerable loss of mercury is thus caused; and the compounds of silver are so transformed or rendered inert as to hinder their reduction, and produce the indications known to the workmen as those of "hot" treatment.

The addition, as a remedy, of lime, ashes, precipitated copper, etc., cools the torta, and destroys the calomel which may have been formed; but it neither reduces the oxidized mercury nor modifies the passivity of the argentiferous compounds.

All the current theories of the patio attribute to cupric or to cuprous chloride the chloridization of the silver in the ore—the copper becoming a sulphide or sulph-antimonide, etc. But many trustworthy laboratory experiments have disproved this proposition. The test is not difficult. Place pure pulverized argentite in a beaker; add cupric chloride in more or less concentrated solution; and the result is nil, as could have been foretold from the principles of thermo-chemistry; since the heat of formation of the chloride of silver is only 29.2 calories, while that of cupric chloride is much greater, namely, 71.2 calories. Adding chloride of sodium makes no difference, even after three months. But on the further addition of iron, or metallic zinc in shavings, an almost instantaneous reaction follows; and the more intense the light during the experiment the more energetic will be this reaction. The black silver sulphide is changed to white. This reaction, no doubt, led Kroncke to employ the cuprous chloride in the method which bears his name. When an excess of iron or zinc is added, the energetic reaction rapidly deposits metallic silver—which is not surprising.

This experiment, studied in the light of Berthelot's thermo-chemical law, confirms the conclusion that the reaction is not a simple chloridization of the silver by the cuprous chloride (the formation heat of the latter being but 29.2, while that of the former is 62.2 calories), but is in large part due to the metallic iron (or zinc). This conclusion can be further supported by similar experiment, in which cuprous silver is used instead of cupric chloride. The resulting reaction is very slow and insignificant.

On the other hand, the hypothesis of the effective agency of the iron encounters at once the objection that, apart from American pan amalgamation, the various silver amalgamation processes do not involve a large consumption of iron; and, moreover, that they produce silver of much higher purity than that obtained in pans, which rarely assays as much as 0.750 fine. It is true that the crushing of ore with modern apparatus exposes it to a certain quantity of iron; that the animals which tramp the tortas are shod with iron; but these factors cannot be significant; since, both formerly and to this day, crushing in stone arrastras and the tramping of the torta by men are performed in remote mining districts of Mexico, with technical results not greatly, if at all, inferior to those of more modern practice.

These objections led me to a series of laboratory experiments which, I think, demonstrate (1) the formation of ferric chloride (Fe_2Cl_6), the formation heat of which, in solution, is 255.4 calories; (2) its subse-

*Transactions Am. Inst. Min. Eng.

Kinkead Mill, Muller Lifted.

ple of the mill is described as being extremely simple, consisting of a cast iron pan fitted with a false convex bottom of chrome steel. A muller, to which is bolted a chrome steel shoe, is, by means of a crank above, given a circular gyratory motion. The ore is fed automatically through the center of the muller, and, having reached a sufficient fineness, is splashed through the screens that surround the pan. The illustration shows the mill with muller lifted and with

quent reduction to a lower chloride, with liberation of chlorine, which, acting in the nascent state upon the compounds of silver, transforms them into chlorides; (3) the reaction of these chlorides upon the hydrated oxides in the mixture of ore and reagents, and on the metallic iron, if resulting in metallic silver with a new formation of chloride of iron, releasing oxygen, and probably affecting a partial regeneration of sulphate of copper; (4) a new formation of chlorides of copper and a continuation of these reactions until the termination of the treatment. This is a resume of my theory of the patio process.

What is the role of the copper in these reactions? Its presence is certainly indispensable. It has always been supposed to play the double role of the chlorination of the compounds of silver and its own sulphatization. As to the latter reaction: the formation heat of the sulphate of silver is 3 calories; that of the sulphate of copper 20.8 calories; and that of the sulphate of iron, in the most unfavorable case, 41.6 calories. Undoubtedly, therefore, if iron oxide be present, this last reaction will be the one to take place. The state of division of this sulphate of iron; the liberation of oxygen in the formation of perchlorides from the oxides of iron contained in all ores; the humidity; the action of light and of atmospheric agents; all contribute to the formation of the sulphate of iron, liberating 94.4, and not to that of copper, liberating only 57 calories. This is only an application of the well-known principle of "maximum work."

Continuing, the formation heat of the chloride of sodium (ClNa) is 58.5; that of sodium sulphide, dissolved, 186.8; that of iron sulphide 94.4, and that of copper sulphide 57 calories. The latter, therefore, will undoubtedly be most easily attacked by the chloride of sodium, since it requires the smallest number of calories to make it resign to the sodium its sulphuric acid, with formation, undoubtedly, of protochlorate of copper, which liberates 71.2 calories.

This simple comparison of the formation heats shows at once the usefulness of the sulphate of copper in the patio process, and also explains the small success of those experimenters who have, in practice, substituted sulphate of iron. The presence of copper is, moreover, of the utmost importance for the preservation of mercury in the metallic state, after the oxides of iron have been transformed into protochlorides; the formation heat of the corrosive sublimate being only 59.6 calories.

It remains to be explained why the "magistral" (i. e., the sulphates of copper and iron obtained by the reverberatory roasting of chalcopryrite) yields, in this process, better results than the English sulphate of copper, chemically the purest in the market. This explanation is simple and completes my theory of the patio process.

All those who have practiced photography have witnessed the effect of light in reducing the silver salts and transforming the proto into the per salts of iron; also the strong solvent action of iron perchloride upon the salts of silver—especially silver chloride, whether it has or has not been affected by light. This solvent power of iron perchloride upon silver chloride is greatly superior to that of the chloride of sodium, though the latter may be more generally known; and it naturally facilitates and accelerates the reactions in the patio. In particular, the chlorination and consequent loss of mercury is diminished, for two reasons: (1) Because the quantity of chloride of copper formed is made relatively small, and (2) because the proto and perchloride of iron immediately formed, instead, from the sulphate of iron of the magistral, directly aid in attacking the argentiferous compounds.

The reduction to silver of the dissolved chloride may be effected either (1) through the precipitation of silver as an unstable oxide by the oxides of iron naturally existing or artificially formed in the ore, or (2) by the conversion of silver proto-chloride into perchloride, leaving free silver, which amalgamates with the mercury, eluding in this way further chlorination and solution. Consequently, mercury should not be chemically lost in this treatment. In fact, the necessary chemical loss has often been shown in practice to be imaginary. The mechanical loss is the only inevitable one.

(TO BE CONTINUED.)

Vanadium.

For some time past the metallurgical world has been busying itself with the peculiar properties of a new alloy of steel called vanadium steel.

It appears, in fact, that if this little known metal be added to steel even in such minute quantities as $\frac{1}{10}$ or $\frac{1}{5}$ of 1%, it confers upon it most remarkable qualities. According to the Journal de l'Electrolyse, the coefficients of resistance of both iron and steel, under all conditions, as of concussion, compression or elongation, are raised from single to double their value by the addition of vanadium; at the same time, its presence renders steel so hard that the union of all these new qualities warrants the reduction of armor plates to half their ordinary thickness. It is indeed difficult to admit that the presence in an alloy of iron or steel of $\frac{1}{10}$ or $\frac{1}{5}$ of 1% of any element what-

ever could have such an intensifying effect and at the same time be so general, which effect is explained by the extreme affinity, under certain circumstances, which vanadium has for oxygen.

This affinity is so powerful that if vanadium—even infinitesimal quantities—he present in a bath of steel in a state of fusion, it will lead to an immediate and absolute reduction of every trace of iron oxide existing in the mass. To these traces of iron oxide in steel prepared with the utmost care, and inevitable without the use of vanadium, is attributed the tendency of steel to crack and rupture.

A singular characteristic of the vanadium steel is that it does not acquire the maximum hardness through tempering, but by reheating to 700° or 800° C.

A variety of consequences occur from this fact. For example: A planer, of which the cutting tool was made of vanadium steel, was set to work at its full capacity as to velocity and power. In a short time the tool began to warm, it even reached a red heat, yet it continued to take off the same chips of wrought iron or castings without showing the least effect from the intense heat. It is scarcely necessary to remark that in such a case a tool of ordinary steel would have completely lost its temper and ceased to further cut the casting.

For projectiles this property is of peculiar importance, for we know that the impinging of a projectile upon an armor plate raises the two surfaces to an intense heat, even to fusion. If, by the presence of vanadium, this elevated temperature does not cause the points to lose their hardness, and, consequently, their sharpness, the penetrative power of the projectile will be greatly enhanced. There will undoubtedly be many applications of vanadium. From a military view point, which interests us above all else, this one use of vanadium will revolutionize the making of armaments, as well as the manufacture of heavy projectile. Incidentally, we may add, it will lead to the manufacture of casques and cuirasses which will be at once light and bullet proof. At one time it cost 130,000 francs to produce one kilogram of vanadium; the reduction process has been so much simplified that the same weight of the white metal can now be bought for 150 francs.

Buffalo Pitts Road Locomotive.

Self-propelling vehicles are in growing demand, and mine owners, contractors and others are generally adopting traction engines for their usefulness and economy. The Buffalo Pitts Co. are furnishing a road locomotive that is used in many different countries under varying conditions. An illustration of one of their makes appears herewith. This engine weighs eleven tons; it will pull from twenty to thirty tons, according to the road and grade, the traction power being, of course, greatest where the engine will not sink in the mud nor slip and where the grade does not exceed 10%. The machine is made of tested material, the grates made to burn wood or coal; the water and fuel storage consisting of tanks with a capacity of 400 gallons water and 1000 pounds coal. On a good, level road the water would carry twenty tons ten miles, and the coal about 20 miles. With eighty pounds M. E. P. on the piston, and 500 feet p'ston speed per minute, the engine is capable of developing 83 H. P. On the second countershaft a compensating gear enables the engine to turn sharp curves without slipping the road wheels. The rear road wheels have steel spokes and rims; diameter of wheel, 72 inches; standard width of face, 20 inches, but made wider, if desired, to suit special conditions. The front wheels are built up in the same way and of the same material, 46-inch diameter, 10-inch face.

The Buffalo Pitts Co. have been established sixty-six years; they have been building traction engines twenty-five years and say that they have constructed over 5000 of them. Their address is 31 Carolina St., Buffalo, N. Y.

An Ore Chute and Bins, Lassen County, Cal.

The elevated tramway, with ore chute and bins of the Golden Eagle mine, the property of the Lassen M. Co. of San Francisco, Cal., at Hayden Hill, Lassen county, Cal., are shown in the accompanying illustration. The tramway is constructed of peeled pine poles, with such sawed lumber as was necessary. Since the photograph was taken from which the half-tone was made a 125-ton cyanide plant has been built

Ore Chute and Bins, Golden Eagle Mine, Hayden Hill, Lassen County, Cal.

on the hillside below the bins, and is now in operation. The tramway and bins were built several months before the construction of the cyanide plant, but were located with reference to the future installation of the plant, showing foresight on the part of the management.

A Type of Desert Deposit.

TO THE EDITOR:—There is a type of metaliferous deposits in the desert regions of California and Nevada that is characterized by being exposed on hillsides, and consists of pockets or kidneys of ore of a greater or less extent. Sometimes these masses contain many thousand tons of ore and at others only a few tons. It would not be fair to the owners to name any specific examples, but these deposits are familiar to all prospectors on the desert, although their origin and possible continuity are puzzles even to those well acquainted with such problems. Various explanations have been given to account for these deposits, but none that I have heard fits the facts as well as the following:

The most characteristic examples are those in the limestone or at the contact of limestone and granitic rocks. That these deposits are more recent than the limestone is evidenced by the fact that while the formation is broken and twisted, the ore deposits are

Buffalo Pitts Road Locomotive.

regular. That these deposits were formed by circulating water there is little doubt, but why in any particular spot?

From studying many of these deposits I have come to the conclusion that they are the results of dried up springs, that is, that the waters of these springs carrying mineral in solution have dried up on coming in contact with the dry desert air, leaving the minerals at a more or less distance underground, accord-

ing to the amount of water and the heat at the surface. If there was sufficient water for the springs to flow from the ground comparatively little mineral would be precipitated, but, as they dry at or near the surface all the mineral is left in the ground. In years of big rains these springs would run and dissolve out enough of the limestone to make space for further deposition.

That these deposits are now forming I have little doubt, for I have seen just such places, characterized by an alkaline stain on the surface, damp generally in the morning and dry during the day. One place in particular was quite close to and between two deposits of red hematite carrying fine crystalline gold, some silver and copper, and on the same horizon, and although at the time I did not think of testing the ground, I have no doubt that a deposit of mineral is forming at that place.

These deposits are difficult to trace underground beyond the limits of the mass, for while the area of deposition near the surface may be quite large, the passage for the solution from some distant point underground may be quite small, in fact only a crack in the formation along which the conditions for ore deposition may have been favorable.

The practical application of this theory in mining is to follow the ore mass as carefully as possible and do not go floundering about with shafts and crosscuts to cut a possible extension or find the original body of ore.

ALGERNON DEL MAR, A. R. S. M.
Pasadena, Cal., Dec. 28.

Mining and Metallurgical Patents.

Patents Issued December 23, 1902.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

WALL CASING SWAGE.—No. 716,466; E. North, Los Angeles, Cal.

A well-casing swage comprising mandrel having shoulder, screw-threaded portion below shoulder and cylindrical portion below screw-threaded portion; an internally-threaded collar screwed onto screw-threaded portion of mandrel and against shoulder and furnished with internal cylindrical portion which fits on cylindrical portion of mandrel.

STEAM SHOVEL OR EXCAVATING MACHINE.—No. 716,538; C. M. Harrison, Napoleon, Ohio.

In excavating apparatus combination of main boom having bracket extending below and forward therefrom, secondary boom mounted to reciprocate upon "axle" in bracket, shovel pivotally connected with secondary boom and means for operating shovel and boom.

OIL BURNING FURNACE ATTACHMENT.—No. 716,486; J. R. Scott, Oakland, Cal.

The combination with oil-burning furnace and burner jets discharging into front thereof, of counter

jet air or steam discharging into chimney or outlet of furnace in direction opposite to outflow of products of combustion.

OIL BURNER.—No. 716,724; V. F. Lassoe, New York, N. Y., and L. D. Lovekin, Ardmore, Pa.

In oil burner, combination air tube, bushing structure fitted into the front end of air tube and consisting of front and back portion forming shallow oil chamber between them and having series inwardly-directed apertures through front and rear walls and opening at front into recessed portion so that several jets may directly impinge upon each other, and oil-spraying nozzle provided with valve feeding oil as spray under pressure into chamber whereby oil is spread in chamber into thin film and atomized by air jets forced through apertures.

EXCAVATING MACHINE.—No. 716,741; C. C. McBride, Redding, Cal.

In an excavating apparatus, combination of traveling carriage having vertical mast, boom attached to mast and projecting forwardly beyond mast and carriage, boom adapted occupy overhanging relation to end face of bank and affording track surface, means for supporting and adjusting carriage and boom for movement in path across, and parallel to end face of excavation, a shovel carrier adapted to track of boom and arranged to travel toward and from carriage, shovel having hinged connection to shovel carrier, and means for operating shovel carrier and shovel individually or collectively.

APPARATUS FOR PRODUCING CAUSTIC SODA BY ELECTROLYSIS.—No. 716,804; E. A. Allen, Rumford Falls, Me., and H. K. Moore, Lynn, Mass.

A cell of character described, comprising non-conducting vertical diaphragm, sufficiently porous to permit percolation of liquid, suitable anode, and

cathode in contact with outer face of diaphragm, cathode being formed of porous layer of such thickness as retain body of liquid in pores, whereby sodium deposited in cathode converted into hydrate by water of undecomposed solution which has passed through diaphragm, and electrolyzing of undecomposed solution in pores of cathode is completed as it flows there-through from edge to edge.

MACHINERY FOR CHARGING STEEL OR LIKE FURNACES.—No. 716,750; A. Patterson, Cardiff, England.

In machinery for charging furnaces, the combination of a suspended frame, means for gripping charging-box into furnace, and means carried by frame for operating ram.

ORE STORAGE AND DELIVERY BIN.—No. 716,769; J. W. Seaver, Cleveland, Ohio.

A bin for storage and delivery of ore or like material, bin having delivery-throat, one wall of which presents step-like formation in plane inclined in respect to opposite wall, steps being separated from each other vertically by fixed spaces into which descending mass of ore can expand.

TREATMENT OF ORES CONTAINING PRECIOUS METALS.—No. 716,847; F. W. Martino, Sheffield, England.

The process of separating noble metals from ores containing tellurium, selenium, sulphur, arsenic, antimony, tin, phosphorus, consists in heating mixture with barium sulpho-carbide and treating it with water, dissolving out the soluble sulphides.

Portable Forge.

The Cumming portable forge illustrated herewith is manufactured by D. Cumming at his manufacturing plant, 787 W. Kinzie St., Chicago.

This forge is a simple one, but indorsed by users as capable of fine work. It has no chains, leather belts or bellows, and it can be easily taken apart and put together again, the parts being all adjustable. When taken apart the heaviest piece weighs twenty-eight pounds, the basin being 18 inches in diameter. There are no breakable parts, nor any to be affected by weather. The basin and pipe are steel, the legs of gas pipe. The maker says it gives a strong, steady

blast, equal to 42-inch bellows. Basin can be slipped off and hose attached to pipe for ventilating, expelling powder smoke in mines. Total weight ninety pounds, height of basin from ground 30 inches. This forge is reported to be in use in many mines and smelters.

Mining Summary.

Specially compiled and reported for the
MINING AND SCIENTIFIC PRESS.

ALASKA.

The oil well at Kayak after spouting for a week has again been plugged and nothing more will be done on this well this season, says the Valdez News.

ARIZONA.

COCHISE COUNTY.

W. Short, of the Short & Mead mine at Cabalona, 22 miles from Douglas, reports a strike in their mine at 182 feet. The ore carries copper, gold and silver.

The Republican says there is a great deal of ore that will come to Douglas from the different mines near Fronteras when the new smelter is ready to receive it.

The Calumet & Pittsburg Co. is down 950 feet on its property and has reached the water level. Work will be resumed as soon as the pumps are in place.

COCHISE COUNTY.

At the Tombstone Con. M. Co. at Tombstone the miners at the combination shaft are clearing drifts in the lower level and making connections, while a number of men are doing preliminary work on the Silver Thread, Comet, Toughout and Lucky Cuss hoists. The company has been hampered by the delay in arrival of supplies owing to the congested condition of freight traffic, the most serious being the non-arrival of coal.

COCONINO COUNTY.

The Azurite Copper Co. has property at Willaha station, 30 miles north of Williams. The ore will be treated in their smelter at Williams. The properties will not be mined, but quarried. The ore is on the surface.

The Redner copper mine, by way of Pine creek, is 60 miles above the Grand canyon. The ore is gray copper. The lowest carload taken out of the mine realized \$2500 at the sampling works at Kingman. One shaft is 100 feet and in the ore body.

GILA COUNTY.

The Old Dominion at Globe resumed smelting last week with one furnace, and has since put on more miners. The result of the efforts to lower the water in the shaft has not been satisfactory, owing to mishaps, says the Silver Belt.

The Blade says D. & A. Williamson's copper property, at the mouth of Dripping Springs wash, has a showing of sulphide ore. They have a tunnel in 150 feet on a vein 30 inches wide, which goes 20% copper, with gold and silver. There are three claims adjoining on which they have prospect shafts.

MARICOPA COUNTY.

The consulting engineer for the Buckeye M. & M. Co., near Bowie, reports the company's new 50-ton concentrator in operation. The test was made on low-grade ore from the dump and produced concentrates carrying \$70 in gold, silver and lead. The mill is running on ore averaging \$16, which concentrates eight to one.

General Manager G. B. Upton of the Oro Grande, at Wickenburg, says he will install a 40 H. P. hoist, air compressor, machine drills, a diamond drill and other machinery. The diamond drill will be used to sink a number of 1000-foot holes on different parts of their property, to test the size and depth of the ore body. The hoist will be placed on the shaft which was sunk 100 feet about 1000 feet north of the main shaft. The north drift is now in nearly this far.

F. McLean and B. V. Hole, of London, Ontario, have a bond on the Powell-Munchas property, near Wickenburg, for \$20,000.

MOHAVE COUNTY.

J. M. Murphy has men at the Pay Roll mine, Chloride. A winze is being sunk on a body of gold ore on the lower tunnel, and a drift is being driven on the south vein.

B. Hastings, superintendent of the Ramrod group of mines near Kingman, is arranging for the installation of a milling plant at the mines.

The Tennessee mine, near Chloride, has reached the 600 level, at which point a station is being cut. An increased supply of water has been obtained for the mill.

The Enterprise M. Co. shipped a carload of ore to the smelter this week. The ore is from the claims of the company near Wallapai Springs.

J. H. Holmes and J. Lane have let a contract on the Wanda mine to sink the shaft now down 100 feet.

The mines of the San Francisco district near Kingman are working full headed. The completion of the road over the mountain gives the mines of the Gold

Road easy access and enables the company to bring in heavier machinery and mining supplies. The site for the Gold Road mill is surveyed. As soon as ore is blocked out and an increase in the water supply obtained, the mill will be started. The Oro Plata mill will be ready for operation in another week.

W. Helmrod will set up a cyanide plant of the Ellis model at Mineral Park. The tailings of the Mineral Park mill will be treated by this method. The process combines both cyaniding and amalgamation.

It is reported that the Hackberry mines, near Kingman, are to start up after a long idleness.

At the Cyclopa property in Gold Basin the cyanide process is in operation. The Senator mine and mill, up the river about 20 miles farther and adjacent to the Grand Canyon, are operating. The ore is hauled 8 miles from the mine to the mill. This mill is the farthest up the river, excepting the Temple Bar.

PIMA COUNTY.

W. K. Maull of Tucson will build a cyanide plant at the Grand Central mill on the San Pedro. The company owns 100,000 tons of tailings. They expect to clean up the bank in three years, working 100 tons daily.

SANTA CRUZ COUNTY.

It is reported that the Nogales Copper Co. will place orders for two 100-ton furnaces, one to be erected at the Buena Vista and the other at the Pena Blanca mines, near Nogales. F. N. Cox is manager.

YAVAPAI COUNTY.

It is reported that a body of ore has been opened in the Gold Dust mine of the Hudson group, near Prescott. The ore is gray copper and runs over \$50 in gold.

The Catocin, on Hassayampa creek, 16 miles from Prescott, is being worked by H. Blauvelt with eighteen men sinking and drifting. The shaft is down 200 feet and a northwest drift is in 200 feet and in ore. Drifting is being done on the 100-foot level. Another shaft 1200 feet down the hill is down 150 feet and a drift started from that point.

A gasoline hoist is to be put in on the Electra mine, near Wickenburg.

On the Lynx Creek placers, near Prescott, there has been considerable activity, says the Herald. Ditches have been dug since the recent rain and snow, giving plenty of water. Five hundred yards from the creek is a gravel bank 300 feet high.

On Hassayampa creek, 16 miles from Prescott, the Quartz Mountain mine is again producing. J. Kompatscher and L. Martin have a two-years' lease and bond on the property, and after driving a cross-cut 370 feet under the old workings have struck the vein. The ore is a sulphide and occasional pockets of telluride have been found.

A discovery of platinum is reported on the Moonlit Wanderer, 8 miles east of Prescott.

CALIFORNIA.

AMADOR COUNTY.

At the Shenandoah, near Plymouth, Superintendent S. K. Thornton says the shaft is down 1000 feet and in the vein.

At the Onelda, near Jackson, pumping is going on steadily from the 2000-foot level, and it is expected that sinking for the 2200 level will begin this month.

At the South Eureka mine, near Sutter Creek, Superintendent Truscott says on the 2300-foot level the north drift is in 140 feet from the shaft and the south drift 130 feet.

CALAVERAS COUNTY.

Work is suspended temporarily at the Salvador, near Jesus Maria.

Manager J. T. Thompson at the Kenross says a shaft is being sunk and work on the ditch is advancing. A number of buildings have been erected. It is reported the Blue Jay will resume. Some work is being done on the Dolphine, the Mauna Bros. mine and the Hamilton property.

A liquidation of 60 cents on the dollar has been made by the Oro Minto M. Co. at Indian creek, near Murphys. The suits pending at Murphys have been dismissed. It is said the Beatrice mine, near Murphys, developed a vein of quartz from 4 to 9 feet in width.

At the Gwin mine the steel head frame is in position and the machinery for the hoist is at the mine. It will be put in position as soon as the foundations are ready.

The Beatrice mine near Murphys has completed installing its machinery and ore is being taken out.—W. B. Lake, of the Echo mine, is having a ditch dug higher up the hill to increase the head of water.—The owners of the Wild Goose mine have finished work on the tunnel for the pipe line. Sinking the shaft is begun.

The Record says work will begin with a gold dredger in a few days on the Stan-

islaus river, from Bostick's bar to Robinson's Ferry. A company has been formed for the purpose and they are putting up a flume. They will start at the lower end and put in the flume to divert the water, and by that means get the dirt and sand down to bedrock. It is to be worked in sections.

DEL NORTE COUNTY.

The Monumental quartz mine on Shelley creek, near Crescent City, is 42 feet wide and carries free gold. The development includes a 70-foot tunnel and a 150-foot shaft. The mine is owned by Baker, Jackson & Hamilton.

EL DORADO COUNTY.

The Republican says the Lucania mine, near Placerville, has closed, owing to a misunderstanding between the mine owners and the parties controlling the water power.

The Larkin M. Co. has been organized to operate the Larkin mine, near Placerville.

The Argonaut mine at Greenwood, owned by J. Smith, has been bonded to Sacramento men.

KERN COUNTY.

The Eastern Con. Oil Co. has incorporated. D. W. Morgan of Bridgeport, Conn., is president. The company has three wells drilling at Kern river.

Supt. J. S. Eggington, the Del Rey Oil Co., south of the Monte Cristo, says they will resume. The Del Rey has five wells. A. W. Craven, superintendent of the St. Paul Oil Co., at Sunset, says his company has completed well No. 1 and will begin another. It is reported that the Queen well at Sunset, closed for some time, has been reopened and is flowing 2000 barrels a day.

The Pittsburg Co. is putting up fourteen derricks at Sunset. More than 100 derricks are being erected in that field. The California Combined Oil Co. has let a contract for a 1500-foot well on section 7-28-28, adjoining the Edgar. The contractors propose to use wire cable, claiming it is possible to drill more rapidly than with the fiber rope.

Near Bakersfield the Claremont is sinking a well. The Associated is now running four strings of tools. Three strings are being operated by the Monte Cristo.

The estimated output of the Kern river field is 25,000 barrels daily, of which 20,000 barrels are shipped and the balance used by local consumers and stored by the Standard, 360 wells being pumped.

NEVADA COUNTY.

T. M. Andrews has taken charge of the Pine Hill mine, near Grass Valley. A 10-stamp mill was recently erected on the Pine Hill; several men are working.

The lessees of the Nevada County mine will resume work and the drift from the bottom of the incline will be extended 300 feet.

PLACER COUNTY.

Superintendent F. R. Hartley has ten men working at the Crandall, below Auburn, sinking a shaft to go 200 feet. They have a 3-foot ledge. The new 10-stamp mill at Black Canyon mine, near Westville, is running.

M. Savage, superintendent of the Deep Canyon mine, 3 miles above Last Chance, says the 5-stamp mill is running steadily.

The Jubilee mine, in the Rock Creek district, near Auburn, is bonded by a company represented by S. T. Nessmith. The company will install \$7000 worth of machinery. The Santa Fe mine at Canada Hill, near Westville, has been bonded.

The Boulder mine, in the Ophir district, has resumed after a shut down caused by litigation. An air compressor has been put in and machine drills added. Twelve men at work.

Buchanan & Norton have started their mine between Auburn and the American river, and buildings have been erected. Six men at work.

RIVERSIDE COUNTY.

The Chicago Co. that bought the O. K. mine near Dale on the Colorado desert will, it is reported, put in a dry crushing cyanide mill. The O. K. mine is over 300 feet deep. J. Sigafus is manager.

SACRAMENTO COUNTY.

The Prosperity mine, Folsom, was compelled to cease operations last week, owing to attachments on the property.

SAN BERNARDINO COUNTY.

The Columbia group of mines, 30 miles west of Manvel, are reported attached for \$3700.

SHASTA COUNTY.

The Modoc Chief quicksilver mine on Clover creek, east of Redding, is reported showing up well with development.

The Mountain Copper Co. is employing a searchlight at night at its property as a precautionary measure.

SISKIYOU COUNTY.

The company which last week bought the Yreka electric light plant intend put-

ting in a larger dynamo to furnish power for the gold dredger at Hawkinsville in Yreka creek, and also to run quartz mills in Yreka and vicinity.

TRINITY COUNTY.

The Sibyl mine near Weaverville shipped nine tons of ore to the Selby smelter last week.

The Lappin mine at Deadwood closed down for the winter on December 10th. The last crushing of 150 tons of ore from the mine, at the Brown Bear mill, went \$33 to the ton. Four tons shipped to the smelter gave \$450 to the ton.

The Journal reports at Bragdon the Keno mine, owned by Thrasher & Rodgers, and the Surprise and Five Pines mines, owned by J. Van Ness, adjoining, have been bonded to Mr. Manning of San Francisco. The Keno has a 2-stamp mill. Fifteen men are at work. The ledge is 5 feet wide, carries free gold and sulphurets, and averages \$10 a ton. A 10-stamp mill will be erected in the spring. A tunnel is being driven on the Surprise to strike the contact and is in 600 feet. Four men are working. On the Five Pines one shift is driving the tunnel to cut the ledge. Mr. Manning is superintending the work.

The owners of the Fairview, on Trinity river, near Minersville, are developing their mine. The ore body was tapped last week in the lowest level and the ledge found to average 2 feet and carry good values in gold. The property was bought last year by San Francisco capitalists, C. Allenberg, Mr. Fontana and the manager of the property, J. H. Porter. A new 10-stamp mill has been built.

TULARE COUNTY.

The Dayton Co., near Angiola, has begun operations in the northwest corner of section 9-23-23, near the Inter Nos. The contract calls for a 1500-foot well.

TUOLUMNE COUNTY.

Manager M. B. Kerr of the Jumper gold syndicate at Stent says he "proposes to connect the 800 level from the Jumper shaft with the 600 level of the Golden Rule. The distance from the Jumper shaft to the Golden Rule shaft is 2000 feet. The ore stoped along the line will be hoisted at the Jumper shaft. All timbers are dipped in heated carboliteum.

At the Dutch mine at Quartz Superintendent Trittenbach says the winze from the 1200 to the 1300 has broken through. With the new boiler, should the water or electric power be again shut off, the mine and mill can be steadily run by steam and with fuel oil.

The Don Pedro G. M. Co. is incorporated to work the properties by that name near Don Pedro bar, the Old Stokes mine being one of the group. The company has its offices in San Francisco. W. H. McClintock is president, S. Sprout, S. T. Gage, C. C. Juster and W. H. Signourney directors.

G. A. Hamilton of Groveland has sold to C. Y. De Lay of San Francisco the Enterprise mine, near Big Oak Flat.

Donohue & Roquet have deeded to W. H. McClintock the Stokes quartz claim, near Don Pedro bar.

W. King has deeded to M. J. Curtin of Sonora the King placer mine, on the Stanislaus river, near Willow bar.

At the Mt. Hood G. M. Co., near Jamestown, stoping is being done from the No. 1 level south. The vein is 12 feet wide. The shaft is sunk in a ravine and there are considerable backs at the point of stoping. A crosscut is being run to the east. The 5-stamp mill is in operation. Five more will be put in. Oil is used as fuel at the hoist. Sinking in the shaft will be resumed this month. J. A. Burkhardt is superintendent.

Superintendent W. H. Turner at the Toledo mine, near Jamestown, says the shaft is down 300 feet and the drift on that level is in 100 feet. The vein is from 7 to 8 feet in width.

Superintendent W. H. Turner at the Rawhide, near Jamestown, says the main shaft has been retimbered and unwatered to the 1500 level, and stoping on the 1200 keeps the 40-stamp mill in operation. The chlorination works have resumed and oil is used in the furnaces. The cyanide works of Robinsons, located on the property, will resume next week.

A strike is reported in the App in the 1100-foot south. The lode is 20 feet wide. The 60-stamp mill is running principally on this discovery. Superintendent Turner intends to open up the 1200 and drift on it to get under this shoot.

The Morris tunnel, near Columbia, is being extended to open new ground and tap the Bald Mountain pocket claim. The name of the Monterey Oil Co. has been changed to the Longfellow Con. G. M. Co., and amended articles of incorporation filed with the county clerk at Sonora.

The New Era says the cyanide plant at the Confidence mine, Confidence, is in operation.

The Sunnyside mine, on the Tuolumne river, near Criter, is getting in machin-

ery and the mill will soon be in operation. The 6-inch pipe for power has an 800-foot head.

At the Clio mine near Jacksonville the mill is running. F. Williams is sinking a shaft on a vein recently discovered on the hill opposite the chlorination plant in Black Leg gulch at Sonora.

The Mountain King near Keltz is being developed by a New York company. Manager Bowers is having hoisting machinery put in.

The Mountain Belle mine, $\frac{1}{2}$ mile north of Soulsbyville, is being unwatered. W. Sbarwood of Soulsbyville has a bond on the property.

A 30 H. P. boiler and engine will be installed by the Contention M. Co. of Knight's Creek, near Columbia. It will be used to furnish power for the 5-stamp mill during the dry season.

Rich gravel is reported struck last week by the Woodside Gravel Co. at Springfield, near Columbia. A \$50 nugget was picked out of the pay gravel.

Ten stamps are dropping with electric power in the Mazepa mill, at Stent.

At the Bell mine, Tuttletown, on the 400 level, 200 feet drifts have been run on the ore shoot and mill tests made every 50 feet. The company proposes sinking 200 feet deeper to 600 feet.

A canvas plant has been added to the Gross mill at Tuttletown.

Work at the Free Lance mine, near Groveland, has been resumed.

VENTURA COUNTY.

The Webfoot Oil Co., owning property 15 miles south of Sunset, Kern county, and a mile across the line in Ventura county, has a well down 700 feet with casing 500 feet. The drill is in sandstone.

YUBA COUNTY.

The Elsie mine, near Marysville, is reported sold to Rosenfelt Bros. of San Francisco for \$20,000.

It is reported that the Miller mine at New York Flat, near Marysville, will be reopened by the Minneapolis men who own it.

COLORADO.

BOULDER COUNTY.

The operators of the Black Cloud mine on Gold hill have opened up a vein of gold and silver ore the last few days. The mine has also developed a vein of lead ore which runs 50%. This property has 5000 feet of development.

W. and G. Rogers are operating on the Little Chief group on El Dorado mountain, near Boulder, and in the Little Chief tunnel at a point 25 feet in they have opened a vein of decomposed carbonates lying in a blanket formation between walls of granite and quartzite. A. A. Merrifield of Fort Collins has finished a 30-foot contract on the April Pool in Hicks gulch. The tunnel is in El Dorado mountain 150 feet on the Clara Belle vein, which shows a pay streak 5 to 6 inches wide running an ounce and a half gold. The vein is 10 feet wide, as far as uncovered, carrying sulphides. Merrifield has also a 30-foot contract on the Manila on East Spencer mountain for the same owner. The tunnel is being driven on the vein.

W. P. Bonbright of the Boulder Illuminating Oil Co. says one of their wells near Boulder is pumping. The Boulder field is producing 400 barrels a day, not including their new well, which is expected to add fifty barrels daily.

CLEAR CREEK COUNTY.

C. J. Hughes, Jr., of Denver, has begun sinking a winze from the lower level of the Comstock mine, near Idaho Springs, on a body of mineral. In the fourth level drifting east proved a body of ore, and it is on this that the winze is sinking. He is taking out milling ore. The streak is of the same width and value as opened through the Dove's Nest several years ago and which proved to be in the Comstock ground. That work was stopped and after nine years of litigation the rights were awarded to the Comstock.

A strike is reported in the Great Scott, in Cumberland gulch, owned by Miner, Purdy et al. In following a small vein 600 feet from the mouth of the tunnel a large lode was cut which shows an ore body 8 feet wide, carrying copper, iron and lead. The find will be tested and if values justify a mill will be built.

Cook Bros. of Yankee have arranged to take the Golden Lily mill of twenty stamps and spend \$2000 in improvements.

A new mill is being considered by the Chesapeake Con. Co. of Yankee, says H. Preston, manager.

Ohman & Reynolds are taking out shipping ore that will run \$100 per ton from their lease on the rich surface shoot of the Puritan.

At the Joe Reynolds mine, near Lawson, the tunnel being driven to cut the old shaft to drain the upper workings is in over 3000 feet and last week reached the winze. It will require 600 feet more to reach the shaft. The company will drive 600 feet farther, make an upraise

and thereby drain the mine without danger. The tunnel will be 50 feet lower than the bottom of the shaft. It will also drain the Two Sisters mine.

The Record says the Sylvania, near Idaho Springs, has a 65-foot ore shoot of smelting ore. It is 6 inches wide and runs eight ounces gold. The vein in which this shoot occurs is 3 to 4 feet wide and runs \$20 in gold and silver.

The Gold Coin Co. at Yankee has a mill in operation on its property adjoining the Sweet Home mine.

An organization to be known as the Home M. & Inv. Co. has been formed at Idaho Springs to develop a gold-bearing lode in Spring gulch.

Manager Hartshorn, at the Pacific mine, Georgetown, says the heading of the drift shows 2 feet of ore worth \$50 a ton.

It is reported that a 2-foot vein of ore has been struck in the Phillips lode, near Georgetown. The property is operated by the Pelican-Dives Co. through the Burleigh tunnel. A drift on the vein has been driven west from the tunnel 700 feet. Zinc ore was found mixed with galena, but which had not enough values to be marketable. The Phillips lode is near the Seven Thirty vein and the ore body cut is 1200 feet below the surface.

The Anglo-Saxon M. & D. Co., operating a group of six claims near Georgetown, have a crosscut in 150 feet, and are in quartz. This crosscut is intended to open up the Saxon vein. A number of veins running in an easterly and westerly direction traverse the group.

The Mendota mine at Plume is shipping solid lead ore, having a value of \$40 to the ton. The veins are from 2 to 3 feet in width. A contract has been let by Manager Old for driving 1000 feet of drifts, the third and fourth levels each to be advanced 500 feet from the shaft. The concentrating material of the mine keeps the mill occupied, the product being lead, iron and zinc.

W. Rogers is about to start up the Baltimore, one of the oldest producers in Silver Plume section. The mine has a record of \$1,500,000.

The Kelly tunnel at Georgetown is making good headway toward the lead-gold deposits of Democrat mountain.

CUSTER COUNTY.

The Bassick mill at Querida was three months ago overhauled and remodeled to meet the requirements of the production of the Bassick mine, but it has proven incapable and it is reported that the Bassick Co. will enlarge the mill to 300 tons a day. At the 1250 level three shifts are breaking ore, but the better grade is found on the 1500 level.

The Elematah will resume after a long idleness. The Aburdix G. M. Co. is the owner; G. W. Avery, superintendent.

Machinery will be installed at the Gold Wonder mine, the newest discovery in the district, as soon as it is determined what process is adapted to the treatment of the ore. The property was discovered six weeks ago, one-half mile east of Silver Cliff.

DOUGLAS COUNTY.

J. J. O'Driscoll, of Colorado Springs has bought a plant of machinery at Cripple Creek, which is to be set up on the Apex mine, in the lower Tarryall district, 30 miles northwest of Cripple Creek. The plant consists of a hoist, a compressor and boiler. He claims that at the depth of 150 feet the bottom of the shaft is in copper ore that runs \$100 a ton. This is the second steam plant in the new camp, the other being operated by F. M. Clancy.

FREMONT COUNTY.

The cement works at Portland are in operation, with 1200 barrels daily capacity.

GILPIN COUNTY.

G. K. Kimball, Jr., and L. Hanchett have arranged for the consolidation of the Wautauga and Old Town properties in the Russell district under the name Old Town Con. M. Co. The property has been producing \$15,000 to \$20,000 a month. The Wautauga has been idle for a greater part of the year, due to litigation. Manager Kimball says that the Old Town shaft will be sunk an additional 700 feet, making 1500 feet, with the intention of striking the Newhouse tunnel level, which will require a total depth of 2400 feet.

The Morning Star and Arizona properties, at the head of Elkhorn gulch, near Central City, are being operated by the Boston-Cleveland M. Co. Operations through the Arizona are discontinued and will be carried on through the Morning Star property hereafter. The shaft buildings have been enlarged to 24x60 feet and a new hoist is being put in. The shaft, 200 feet deep, is being retimbered. The company will sink 200 feet deeper.

The Central City Register-Call says a large amount of location and development work is being done on the south slope of Hanna mountain and along South Boulder creek, in whose vicinity the new Moffat

railroad will pass.—The Walter A. shaft of the Tungsten M. & M. Co.'s property, on Jenny creek, is being unwatered.

The Oneida G. M. Co. is incorporated to operate in Gilpin county; A. R. Sexton, E. F. Irish and H. H. Schuler.

Baleria & Co. of Central City, who are working the Homestake mine in Lake district, made a shipment last week to the sampling-works of sulphide copper ores. They will make a shipment of second-class ores to the Golden smelters this week. Both ores are coming from the shaft in sinking and a depth of 300 feet has been reached.

At the Hampton mine in Russell Gulch a shipment of fifteen tons of enargite ores is to be made next week. Several tons of second-class ores are on hand.

Manager J. A. Gilmour of the Stewart G. M. Co., operating in Hawkeye district, near Central City, received returns last week from a mill run of ten cords which ran four ounces gold per cord on the plates. The tailings, amounting to eleven tons, gave \$9 per ton, bringing the ore up to $4\frac{1}{2}$ ounces gold per cord. The ore came from the east 170-foot level.

H. Pool and associates made shipments last week of smelting ore from their lease in the McCallister property, on German mountain, working through the Bobtail tunnel.—Missourians, who own the Old Ann group at the head of Silver creek, gave a contract for drifting last week. The sinking contract is completed and the shaft is down 300 feet.—Increased shipments are being made from the Clark-Gardiner mine on Quartz hill, the product being treated at the New York mill at Black Hawk.—A number of leasers are at work on properties of the Hillside G. M. Co. in Gregory district and regular shipments are being made to the mills.—The ore bins at the Clay County mine in Lake district being filled, shipments have begun.—Leasers working the Puzzle mine on Bobtail hill made shipments last week to the sampling works.—Regular shipments of milling and sampling ores are being made from the Galena mine near Central City. The ores are being shipped both on company and leasing account.—Sinking is being carried on at the East Boston mine with two shifts and the property is shipping ore to the stamp mills. S. Hoskin is manager.

GUNNISON COUNTY.

Operations at the Augusta mine the past year have been confined to development in the 320 level and the driving of a tunnel from the Pittsburg side of the mountain. The 320 level enters from the Dark canyon side and is on the vein 1200 feet, 700 feet of which is in ore. The east 100 feet has been in a body of quartz containing ruby silver and zincblende, which carries gold values. The big tunnel was started a year ago and is in over 1900 feet. The depth on the incline of the vein below the outcrop at the surface will be 1500 feet when the new tunnel reaches it. Several parallel veins have been cut. The Augusta M. M. Co. expects to complete this tunnel next spring, when a mill and a tram line will be built. An electric plant is also contemplated. The mine's output will be 100 tons per day.

HUERFANO COUNTY.

The Chieftain says numerous locations are being made by coal prospectors in the Huerfano valley along the proposed line of the D. & R. G. railroad between Pueblo and Walsenburg, now being surveyed.

LAKE COUNTY.

The Republic S. & R. Co., which will operate the Boston gold-copper smelter at Leadville has filed its incorporation papers. T. Goodwin is manager.

A contract has been let for driving a 700-foot tunnel on the Best Friend property in upper Big Evans gulch, near Leadville. This will be driven along the vein and tap the shaft at a depth of 300 feet. The work is being done jointly by owners and lessees.

The Lillian mine on Printer Boy hill, near Leadville, is producing 100 tons per month of gold ore. Nine men are at work on the block leasing plan.

A heavy flow of water in the Diamond shaft, in upper Evans, Leadville, has been overcome and developments with drifts and diamond drills are again under way. The company is searching for the extension of the deep-seated ore bodies developed in its neighbor, the Resurrection.

Suits against the Boston G.-C. S. Co. have been dismissed in the district court as a part of the plan of that company's reorganization. The suits were brought a year ago by mining companies to recover the value of ore left at the defendant's smelter. At that time the Boston Co. operated a pyritic smelter at Leadville, which had a capacity of 450 tons a day. It closed down in September, 1901, and suits aggregating claims for \$100,000 have since been brought against it. Arrangements have been effected with the Republic S. & R. Co. by which the old plant will be remodeled and work renewed.

LARIMER COUNTY.

It is reported that rich galena has been found in the Big Creek tunnel at Pearl 960 feet from the mouth of the tunnel. The rock is a grayish-white quartz containing a large percentage of copper and galena. The main body of ore is low grade.

OURAY COUNTY.

A syndicate of local capitalists is being formed to work a group of claims lying between and adjoining the Camp Bird and Revenue mines. A number of claims have been secured and negotiations for others are pending. The territory between these two properties is mineralized and there are a number of large veins with good surface values.

The net profit to the stockholders of the Camp Bird mine for October was \$151,000. It is reported that the Camp Bird will erect an electric power plant in Ouray and an aerial tram from the mills to Ouray.

SAN JUAN COUNTY.

In the Bachelor, near Ouray, rich silver ore carrying native silver has been struck. The shipment of ore from the Khedive and Bachelor is equal to the output of the mill. The mill at the Khedive is running and the values in the tailings are small. The process of making two separate products in the mill is a success. The zinc is almost totally eliminated from the other product, which carries the silver, a small portion in gold and the heavy percentage of lead.

SAN MIGUEL COUNTY.

The Smuggler-Union mine stock was brought up from the valley. Seventy-five men are at work. They have cleared away snow and put the mill in shape and stamps are dropping again.

SUMMIT COUNTY.

At Robinson the Ten Mile L. Co. has made a strike in the Dalzell shaft on one of the company's claims. The strike was made on the contact in the bottom of the shaft at a depth of 985 feet last week. The company has for two years been sinking for the Robinson contact and several ore streaks have been found, but drifting proved them to be stringers.

Another strike has been made on the Carbonate claim, near Breckenridge. The locators found the float and drifted 50 feet. A winze was sunk 20 feet and a 22-inch streak of lead ore was uncovered. A carload hauled to the sampler netted \$50 per ton and 60% lead, one-half ounce in gold and forty ounces silver.

The Admiral M. Co.'s claims on Missouri gulch above Frisco will soon have their buildings completed. A turbine water wheel is in position to run the motor for the air compressor and air drills, but the dam in Ten Mile is not completed. A steam plant will be installed for this season. The ore is sulphide, the mill equipped with concentrating tables and a roaster.

The Mountain Pride, on Baldy, near Breckenridge, is working. Manager Findling reports a shortage of water for milling. One shift is working in the mill. The company's output in smelting ore and concentrates is 100 tons per month, which goes to Denver smelters.

The Gold Pan M. Co., near Breckenridge, has received two locomotive cranes which weigh 43,000 pounds each and have a lifting power of two tons on 50-foot radius and six tons at 25-foot radius. The cranes will run on 8-foot gauge and are to be used in the placer operations next summer.

Kokomo mines are shipping steadily. The Colonel Sellers on Elk mountain ships fifty tons of sulphides daily.

The Wilfley mine and mill is working steadily, shipping good grade ore. This mine has made a steady output since 1879 and still producing under management of E. E. Byron.

The Free America on Jack mountain is working steadily and the incline is being put down in ore. F. Linsley is manager and also owner in the property. Zinc ore showing free gold can be seen.

TELLER COUNTY.

The Rocky Mountain M. Co. is pushing work on the three-compartment shaft on the south end of the Delmonico, Cripple Creek district. The property is producing twenty-five tons per week.

Lessee C. Leonard, on the Doctor-Jack Pot property, made a shipment of ore last week from the seventh level to the amount of 544 tons, which returned \$10,000. The company will receive \$4000 in royalties.

The Times says on the Hull City of the Cripple Creek M. Co., Cripple Creek, the lessees are taking out fifty-six tons of ore per day that runs \$30, and have proven the shoot for 600 feet. From the present level they have 300 feet of stoping ground.

The Maria A. G. M. Co. has granted two leases on its property, the south half to J. R. Stevenson and the north half to Toof & Elder. Leases run eighteen months at 20% royalty. Both employ

forty shifts monthly. The Maria A. is in the saddle between Raven and Bull hills, Cripple Creek district.

W. Vnst of Victor has a lease on ground on the Mountain Beauty, Bull hill.

Temple & Rice have a lease on the Van Fleet sampler at Goldfield and are converting it into a cyanide plant. They expect to handle 250 tons daily. They have leases on several dumps of ore that run from \$4 to \$7 a ton, and with reasonable transportation charges expect to handle the rock at \$2.50 a ton.

Moro ore is being sent out from Cripple Creek district mines on the south slope of Bull hill than over before. The showing in the Vindicator is good. At the tenth and twelfth levels there is a shoot proven for 600 feet, and in places the ore body is 15 feet wide. The grade of the ore is about \$20 a ton. On the Golden Cycle there is ore enough in sight to continue the present production of 100 tons a day for some time. On the Hull City placer the Cripple Creek M. Co. has a good showing in the 800 level, some of the ore being rich. On the Trachyte, Deadwood, Delmonico and Shurtliff, worked by lessees, steady shipments are being sent out.

Wilhelm and associates, leasing the Wilson, owned by the Free Colnago Co., have sent out another high-grade shipment of fifteen tons. The last carload averaged \$400 to the ton.

The Mint property on Gold hill, Cripple Creek district, is getting ore from the second level that gives values of two ounces to the ton. The lessees on the third level are driving to cut the same ore shoot as above and expect to reach it by February 1. Lessee G. Bent, working on the Bonanza King on Gold hill, made a carload shipment of two-ounce ore last week.

A. Hickman, on the Sheriff claim on Raven hill, Cripple Creek district, is taking ore from a 4-foot vein that will average \$40 per ton.

It is reported that the property of the Cripple Creek & Colorado M. Co. on Gold hill, of which R. G. Mullen is manager, will resume. A shipment of twenty-five tons returned good values. The ore was broken on the 500 level.

The returns on ore shipped by Lessee Leonard from the seventh level of the Doctor-Jack Pot, Cripple Creek, show that 12 1/2 tons ran 20 67 ounces; 19 1/2 tons ran 7.02 ounces, and 22 07 tons ran 5 48 ounces. The royalty received by the company was \$3756.

The Globe M. & R. Co. has been organized to mine and treat the low-grade oxidized ores of Cripple Creek by means of cyanide. The company has a four-years' lease on the property of the Standard M. Co., also on the Van Fleet sampler. New tanks will be put in. W. O. Temple is manager.

The cyanide mill of Nesbitt & Miller at the Pharmacist, Cripple Creek district, began operations this week.

IDAHO.

ADA COUNTY.

State Mining Inspector Jacob estimates the mineral production in Idaho for 1902 at \$10,924,371 83—gold, \$2,467,233.21; silver, \$5,421,583.62; lead, \$3,035,655.

The copper mines of the Seven Devils district were shut down all year on account of litigation, and other copper property at Mackay, which has a \$1,500,000 smelter, will not begin operations until next spring or summer. Of the total mineral output the lead-silver mines of the Coeur d'Alenes contributed \$6,247,327.

BLAINE COUNTY.

The Minnie Moore, near Hailey, is shipping a carload of ore per day, which runs 124 ounces silver and 80% lead. The vein from which this ore is taken is 9 feet thick. Mr. Rockwell, the owner of the Minnie Moore, has taken an option on the Red Cloud in the same district and has begun work. This mine has produced \$1,000,000 from near the surface.

W. H. Watt, owner of the Democrat, is 1500 feet in on a 3000-foot tunnel, run to catch a vein on a lower level, which produced ore running 120 ounces silver and 60% lead.

The Elkhorn mine has resumed after being idle for seven years.

In the Smokey district the Liberal, a gold mine, owned by Mr. Reed of Boise, with Eastern people, is being worked; also, the Williams Bros. claim, a new group opened up, which shows \$12 per ton.

BOISE COUNTY.

The pumps were pulled from the Washington shaft, near Idaho City, recently. The ore bin was filled, and, being unable to run the mill, the fuel being green, work is suspended until spring.

CUSTER COUNTY.

The Shakespear claim, adjoining the Packer on Loon creek, near Custer, will be developed this winter. In Valley creek the 20-stamp mill belonging to Judge Price has been completed and will

start up in the spring. Work will continue all winter at the mine. The dredge of the Stanley Basin Placer Co. is finished and everything ready for operation in the spring. All work has been discontinued at the property of the Hartford Co., at Custer, pending a reorganization of the company.

FREMONT COUNTY.

W. Hill, superintendent Teton Coal Co., in Teton Basin, says he has opened up a stratum of coal nearly 20 feet in thickness and is now supplying the market of the valley. The vein lies near the proposed railroad through the basin to the Yellowstone National Park.

IDAHO COUNTY.

At the Silver King, near Warren, a tunnel is being run to tap the ledge at a depth of 700 feet. Repairs and changes are being made in the mill.

The Dewey mill, Thunder Mountain district, is running five stamps, the others being hung up because of a broken cam shaft, which can not be replaced until spring.

LEMHI COUNTY.

The Italian mine has been bought by S. S. Vanhorn of Nevada; E. B. Randolph installed as superintendent.

The Gold Dust M. Co. of Leesburg is installing a 10-stamp mill.

SHOSHONE COUNTY.

Owners of the Oom Paul, a silver-lead property near Burke, are driving a cross-cut tunnel, under contract, which is near an ore body. The tunnel is in 800 feet and will give a depth of 250 feet.

WASHINGTON COUNTY.

H. Thorp, superintendent of the Grouse Creek Placer Co., operating the Hathaway hydraulic properties on Grouse creek, in the Marshall Lake district, near Council, says they have stopped work for the winter, being unable to haul supplies.

MICHIGAN.

HOUGHTON COUNTY.

The Calumet & Hecla, at Houghton, has erected pulley stands for emergency hoisting from No. 7 shaft.

The Franklin mill, Houghton, is stamping 1000 tons of rock daily—750 tons from the Junior and 250 tons from the old mine. The conglomerate shaft is sinking to the 15th level. The 7th level drift south is in 1100 feet—100 feet from the site proposed for the new shaft. The new dry, replacing the one recently destroyed by fire, is occupied.

MISSOURI.

It is announced that work has begun on the construction of the Mines and Metallurgy building of the St. Louis World's Fair. The building will stand in the southern part of the main group and will be 525x750 feet, covering nine acres. It will cost \$493,000. With the building erected, it will be necessary for the people of the mining camps of America to see that it is filled, as Dr. Ward has stated, with the best exhibit of minerals ever displayed.

MONTANA.

FLATHEAD COUNTY.

W. J. Beager reports that he has sold the Cedar group of claims on Libby creek to Eastern parties for \$30,000. There are five claims in the group. The ore is said to be free-milling.

MADISON COUNTY.

The White Star group of five claims is handed to Michigan men, represented by F. C. Lavigne. The bond calls for the payment of \$50,000, of which 10% was made as soon as the papers were delivered. The property is near Goodrich gulch, 8 miles from Twin Bridges. The ore is free milling gold and the tailings will yield to the cyanide treatment. Lavigne says from fifty-two assays the lowest return was \$6. It is the intention of the Michigan men to build a 40-stamp mill and cyanide plant. They will develop the vein by a tunnel, which will be driven 700 feet before the ore body is cut at a depth of 400 feet.

SILVER BOW COUNTY.

The Montana G. M. Co., near Butte, shipped last week to the United States assay office at Helena a \$2500 gold bar, the result of nine days' run on ore from the Sunday mine, which the company has under bond and lease, also having a lease on the Royal mill.

F. Farrell has taken up his option on the McQueen placer, a portion of the ground he recently acquired. It is understood he paid \$500,000, and his company, the Pittsburgh M. Co., will build a smelter.

A strike of copper is reported in the Lexington mine—a silver property—near Butte. It lies at the northern edge of the known copper belt.

The Standard says that with the exception of fifteen men the miners and other workmen employed at the Mountain Con. mine, owned by the Anaconda M. Co.,

Butte, were laid off last week for a month, as a result of a decision on the part of the company to retimber a portion of the shaft, which is 2200 feet deep. The men retained comprise the timbering crew and framers. The temporary suspension of operations at the mine throws 400 men out of work. The other mines of the company are to be kept in operation. The Green Mountain has also been closed down, but employs a few men.

NEVADA.

ELKO COUNTY.

At White Rock the Edgemont Co. is employing forty-five men and running its 20-stamp mill full capacity. Thirty men are employed in the Curlioux mine and ten stamps are dropping there. The Riddle mine has been bonded by Eastern men for \$100,000. There are few men working in the White Rock placers. As soon as there is sufficient water a large number of miners will be employed.

ESMERALDA COUNTY.

A group of mines at New Boston is reported sold for \$6000.

HUMBOLDT COUNTY.

The Lovelock Tribune reports a strike of horn silver in the Victor tunnel at Arabia district.

J. C. Hampton has sold to J. McClure the Gold Bullion mine at Unionville.

The mill at Mill City is running on ore from the Arizona mine at Dun Glen.

The Sheba Co. is to build a mill at Star City.

J. T. Kessel, superintendent of the Sheba mine, says the lower tunnel is in 275 feet. According to the survey, the main ledge should be tapped within 60 feet at a vertical depth of 700 feet. He expects to have the mill in operation February 1.

LINCOLN COUNTY.

Activity in mining along the Colorado river is increasing. A great deal of ore has been discovered lately.

The company owning the Rattan mine has built a mill at Hardyville for prospecting purposes; eight stamps are being operated. Later a 20-stamp mill will be built.

The El Dorado Canyon mine, idle for a number of years, is owned by an Eastern company that will shortly resume work.

At Searchlight the Duplex M. Co. is making some changes on its group of claims. The mill is on the Searchlight ground. The Ella, which lies over the hill to the east of the Searchlight, and between the Piute and I X L, will be connected with the mill by rail via the Fraction, from which point a spur will be run to the New Year's Gift. On the Ella is a shaft and an open cut, which exposes the lead for 60 feet. On the New Year's Gift a hoist is to be installed and sinking commenced. A crosscut is started from the 400-foot level in the Searchlight towards the Fraction and New Year's Gift. In the mill a centrifugal pump has been connected with the settling tank to raise the water back to the mill tanks. Manager Swindler has thirty-five men on the payroll.

Armstrong & Loop, owners of the Red Cloud mine near Goodsprings, report that from the main shaft drifts have been run north and south in ore. This property is the only known cinnabar mine in the Yellow Pine district.

Workmen are putting up a 32-foot gallow frame over the Good Hope shaft, at Searchlight. The hoisting machinery is on the ground. H. A. Perkins, manager of the New Era Co., is having development work done on his El Paso group. While the Quartette mine is closed down ore bins are being built in the gallow frame which will have a capacity of 400 tons. Twelve men are working on the millsite. P. Johnson is superintendent of construction.

LYON COUNTY.

The Douglass group of copper mines has been sold to a British Columbia company.

NYE COUNTY.

Last week an 8-foot vein was cut in the Colehan-Gold Mountain property, Tonopah, that went \$30 in gold, and on the Fraction an ore body was found in shaft No. 5, 400 feet west of the old strike. The rock contains wire silver.

The freighters of Tonopah have given notice that the rates for incoming freight will be increased from \$20 to \$25 per ton, as there is not sufficient ore being shipped out to supply outgoing loads for the teams.

The Tybo M. & R. Co., at Tybo, has closed down for the winter, pending the installment of a compressor and concentrating plant.

The main three-compartment shaft of the Mizpah at Butler is down 500 feet and one crosscut started to cut the ledge and another to tap the Valley View 700 feet distant. At the 490 level drifts have been run on the ledge several hundred feet either way. More development work has been done on the 300 level than in any

other part of the mine. The east drift is within 100 feet of the end claim and in ore. From the 300 station a crosscut has been run south 850 feet to connect with the Valley View, an adjoining claim.

The Aspen, San Sabe and Black Diamond claims, near Butler, were sold last week to T. J. Lamoureux of Oakland, Cal. The group lies 1 mile north from the central mines. The 25-foot shaft on the Aspen is to be enlarged and a hoisting plant put up.

The Tonopah Chief Co., east of the Mizpah Extension, near Butler, will sink their main double-compartment shaft to 200 feet and crosscut.

Recently while excavating at Butler wells, 4 miles from Butler, for the site of his mill, W. Osborn opened up a 2-foot ledge of quartz, and assays of the rock showed values in silver and gold, says the Miner.

H. Mead, who has been prospecting between Lone mountain and Silver Peak, reports locating five claims, one of which produces high-grade ore. No work has been done on any of the claims. The veins are 3 to 4 feet wide. Preparations are being made to sack and ship the ore.

WASHOE COUNTY.

At Olinghouse the three mills in camp are running steadily. The Belcher mine has a shaft down 75 feet, from which a drift is being run in ore. The Forlorn Hope has 300 feet of workings in ore. A stringer of rich ore is being followed.

The No. 2 has a body of ore on the surface which has been cut at 80 feet in the shaft. Twenty tons milled returned \$20 per ton. The shaft has been retimbered. Several hundred feet of work have been done on the No. 1. There are 100 tons of ore on the dump, which will be milled. At the Gold Center E. Olinghouse has 100 tons ready for the mill.

The Cabin mine, owned by W. C. Williams, is in operation. At the Cabin No. 2 the tunnels are being strengthened, the mine retimbered and the track relaid with iron rails. The Hutchinson has an incline 75 feet in ore. The Jumper is stopping ore from the 150 level.

Another strike is reported at the Wedekind mines, near Reno.

WHITE PINE COUNTY.

Contractors will drift 500 feet on the 700 level of the Star mine, near Cherry creek.

Work has been resumed on the Morris mine of the Groux-Snedaker Syndicate, near Ely. The ore being broken in the bottom of the Groux shaft contains copper sulphides.

The 54-foot gallow frame on the collar of the Copper Flat shaft, at Ely, and the hoist will be in operation next week. The new shaft, 775 feet distant from the old one, is already in copper ore.

The Rocco-Homestake Co., whose mines are at Hamilton, is reported to have opened a large body of carbonate ore, the best strike ever made by the company. The ore will run 36.5 silver and 71.5 lead. The thirteenth dividend of the company has been paid, the company having paid \$69,500 in dividends to date.

NEW MEXICO.

DONA ANA COUNTY.

A new rock crusher will be put in at the Modoc mine, near Las Cruces.

COLFAX COUNTY.

Drilling for oil on the McKown ranch, near Raton, is begun by the New Mexico Oil & Gas Co.

RIO ARriba COUNTY.

P. Sanchez was killed last week at Glenwoody camp, 3 miles from Rinconada, by a shot which had missed fire. He picked out some of the tamping and put in new powder and a cap. He tamped it too hard and the shot exploded, killing him.

OREGON.

BAKER COUNTY.

The raise from the 200 level of the Golconda, near Sumpter, opened 2 feet of ore in the east vein that runs \$100 a ton.

N. Gelder of New York has an option on the Buckeye group of mining claims on the Elkhorn divide.

The North Pole M. Co., near Sumpter, has completed the tramway from tunnel No. 4 to No. 1, on the northern terminus of the main aerial tram. The new line is 2500 feet long and makes a lift of 1190 feet and passes the mouths of tunnels No. 2 and 3. Buckets on the main tram carry 250 pounds and hang 100 feet apart. The new tram is claimed to have an equal capacity.

President Wright says a 10-foot ore body has been opened in the third vein of the Bluebird property, near Sumpter. It is intended to drive 250 feet and raise to the top. This work is being done by hand, but as soon as the development plant is installed machine drills will be used.

The Big Horn group in the Cracker Creek and Red Creek districts is reported

sold to the Killen, Warner, Stewart Co. Four claims are in the property, one crossing the North Pole divide and the others in the Rock Creek basin, all on the same fissure. This is the third property the firm has acquired in the Cracker district. Two others, the Cracker Eagle and the Cracker Summit, are being developed.

At the Golconda, near Sumpter, ore assaying \$100 is being sacked on the 100-foot level. The same shoot has been cut on the 300 foot level, but the width is not yet determined. The main tunnel is being driven toward the point of outcrop, following a vein 7 feet wide of milling quartz. Last week connection by upraise was completed between levels two and one. Connections were recently made between levels three and two and from the first level to the surface. Ladders have been placed in these upraises, that they may be used as exits.

W. H. Mead of Spokane, Wash., has taken up his bond on the Gladstone group of five claims near Sumpter. Mead and associates are organized as the Interstate M. Co.

The Big Four G. M. Co. has incorporated at Baker City to operate in the Blue River district; T. N. and J. E. Segar and C. A. Hardy.

The Daines M. & M. Co. of Spokane, Wash., owners of the Belcher group, in the Greenhorn district, near Baker City, has bought the Golden Gate, adjoining the Belcher, for \$10,000. A mill is to be erected in the spring to handle the ores of both properties.

A company has been organized in Baker City to be known as the Golden Star Gold Mines Co., W. E. Grace, Baker City, president. The Golden Star group of three claims on Olive creek in the Greenhorn district with a mill site, water rights and timber, has 600 feet of work. They will sink a double-compartment shaft. A mill will be built.

At the Bonanza mine, near Sumpter, it is reported the vein has been opened on the 800 level. The mill will resume next month.

E. Butze, of Baker City, superintendent of the Northwest Coal & Iron Co.'s gold mine near Sumpter, says a vein has been cut in the tunnel, being driven on the Colorado, and the Gould & Curry, which they own, and that the ore carries a telluride of gold. This tunnel, in about 140 feet, is being driven by contract, with two shifts.

The Psyche 20-stamp mill in the Greenhorn district is in operation. J. T. Eden is superintendent. In the vicinity the Phoenix mill, with ten stamps and Bryan roller mill will be in operation next month.

At the California mine, near Sumpter, construction work is going ahead. The steel cable for the 2800-foot Hallidie tramway is being strung on the towers. At the mill the third section is up and the superstructure will be enclosed next week. This mill will be a concentrator with fifty tons daily capacity. All of the timbers and lumber used were cut at the company's sawmill.

At the Oregon Monarch, near Sumpter, the crosscut on the adit level has cut five ledges, two of them the past month. The first of these is from 2 to 4 feet in width, and dips in the opposite direction to the outcropping veins. The ledge was cut 375 feet from the mouth of the tunnel. The tunnel is in 400 feet, with a vertical depth of 250 feet. The air compressor at the Red Boy supplies the air to the drills.

GRANT COUNTY.

A strike is reported in the Strassburg, near Alamo, in which W. H. Remington and W. S. McCormick, of Salt Lake City, Utah, are owners. There are three tunnels on the property; No. 1 is in 700 feet; No. 2, 1000 feet; and No. 3, 500 feet. No. 3 tunnel is being driven on contact, and the strike was made 200 feet beneath old workings. The lead is here 20 feet wide. A 40-stamp mill is proposed. The Strassburg group consists of six patented claims.

On the Alamo, near Alamo, six men are extending the lower tunnel, which is in 900 feet. They expect to cut the main lead next week. W. H. Chambers is pushing development on the Big Producer group of eleven claims. On the Humpback of the Van Anda group, adjoining the Strassburg, three men are at work. The Oregon & Colorado M. Co., owning the Quebec group, have six men developing. The 10-stamp mill will resume.

JACKSON COUNTY.

The Western Star M. Co., operating near Medford, is running a tunnel on the ledge and has cut a body of quartz that carries high values in gold. Six men are working on the Whale tunnel. The number will be increased and a crosscut tunnel begun 200 feet below the workings. The ledge is 12 feet wide where the pay rock is found. Dr. Damourette is the president of the company.

The Record says work is being done on

the placers of Coleman creek, near Ashland. D. B. Reame has resumed work on his ground.

J. Layton, owner of the Layton placer mine in the Applegate country, has leased his water privileges for the season to Watson & Durham of Portland.

JOSEPHINE COUNTY.

The Greenback mine of the Grave Creek district, near Leland, has its 20-stamp mill in operation. A 15-stamp mill was reduced to five stamps, which will be used for sampling. The new mill was built farther down Greenback mountain. The crew has been increased, drills added, a hoist put in, larger engines and boilers installed and electric lighting and cyanide plants added. The mine is opened to a depth of 800 feet.

A 4-stamp mill is being set up at the Fremer and Palmer mine on Mount Reuben, near Grant's Pass.—The Gold Bug mine, on Mount Reuben, has closed for repairs.

The New York & Western M. Co. has bought the Oregon Belle mine, near Grant's Pass, for \$30,000. The Oregon Belle, in depth, shows a body of ore carrying free gold and sulphurets. A Huntington mill on the mine has been operated by former owners. The new owners will develop the property. They will put in a large mill as soon as they have the mine sufficiently opened.

SOUTH DAKOTA.

LAWRENCE COUNTY.

A cyanide plant of 300 tons daily capacity is being operated by the Spearfish Co. at Ragged Top, 8 miles south of Deadwood. The cleanups amount to \$25,000 a month. The ore is lime shale in flat blankets. The company owns thirty acres.

The Alder Creek M. Co. is producing \$7250 in gold monthly, at the cyanide plant on Yellow creek, a mile and a half south of Lead. The ore is in cambrian quartzite and porphyry, with a value of \$4 a ton. The plant has a capacity of sixty tons daily. The crushing machinery will handle 150 tons and the company is planning to add more tanks in the spring.

On the same creek the Wasp No. 2 M. Co. is running a 100-ton cyanide mill and cleaning up \$9000 a month. The average value of ore per ton is less than \$3. Everything in the mine is run through the mill that carries over \$1 a ton. Improvements have been made by driving a tunnel through the hill, shortening the haul. A new dryer has been installed.

TEXAS.

JEFFERSON COUNTY.

It is reported that the Standard Oil Co. has obtained control of the Beaumont oil fields and also has been buying every independent field around Beaumont. Hundreds of wells have been sunk.

UTAH.

BEAVER COUNTY.

The new lead furnace for the Lewis smelter at Milford has arrived. The smelter will be ready to blow in by the latter part of January.

BOX ELDER COUNTY.

S. Simon, president Sunrise mine, near Park Valley, says the tunnel is in 450 feet. A stringer of ore was struck recently which showed 3 feet of values. The management thought this was not the main vein and continued this tunnel and are now breaking into the lead. The Sunrise property adjoins the Century.

A strike is reported in the Bluebird, on Dom creek, Park Valley. Ore was encountered in the main tunnel at a depth of 175 feet, carrying values in gold, silver and copper.

Four feet of gold ore and enough water to run five additional stamps have been struck in the Century mine at Park valley. Manager P. W. Madsen says he shipped a \$2300 bar of gold this week and a car of concentrates running \$75. The bar of bullion represents ten days' run at the mill.

Articles incorporating the Osborne M. and M. Co., with Salt Lake as its principal place of business, have been filed; P. W. Madsen, J. A. Jennings, E. W. Madsen, J. H. Cline, C. S. Price. The company will develop the Osborne claims Nos. 1, 2, 3, 4, 5, 6, 7 and 8, in the Park Valley mining district.

IRON COUNTY.

Manager G. Smith, of the Margaret property at Stateline, says a strike has been made in the west drift from the 220 level of the new double-compartment shaft. To the east bodies of ore have been previously opened and the drift west was started with the purpose of tapping a shoot believed to exist on that side. At a distance of 150 feet from the shaft the ore began to make its appearance.

C. A. Short, manager of the recently incorporated Jennie Co.'s property in the Stateline district, has men at work. He

intends to put up a mill during the coming season.

JUAB COUNTY.

J. Eustice of the Emma Jane group, west of Eureka, says the shaft is down 120 feet on the ledge and shows rock carrying values in gold, silver and copper.

A train composed of eighteen cars of Grand Central ore was shipped from Mammoth Dec. 27, which was the largest shipment ever made from the mine in any one day.

The Centennial Eureka tram at Tintic has been overhauled to carry the increased load, and the mine will send out 200 tons of ore a day to the new United States smelter in Salt Lake valley. The tram was first built to care for half that amount, but was run at a 200-ton speed. This being dangerous, the braking arrangements were remodeled.

The Grand Central, at Tintic, it is reported, will be able to increase shipments of high-grade with the new year.—The Star Con. is working a good body of ore.

The Laclede mine, T. Welr manager, is shipping. The breast shows 4 feet of ore, carrying values in silver, copper and gold.

At the Ajax two donkey hoists have been put in the winze in the north drift on the 1000 level and a hoist in the south drift, which is 275 feet from the Lower Mammoth line.

Two cars of ore from the Carls Co.'s property at Tintic were disposed of recently for \$4900. One car assayed \$168 gold and ten ounces silver while the other was copper ore running 28%.

A body of ore has been opened up in the Utah mine at Fish Springs. This ore assays 25% lead and 500 ounces silver. This is on the third level. On the fourth and sixth other bodies have been encountered. A 50-gallon per minute pump is being put in and sinking will resume.

SALT LAKE COUNTY.

Last week the Mystic Shrine's new tunnel at Bingham, which is following a fissure and has been driven 100 feet in the past two months, broke into a body of copper-bearing ore. Manager Young says the main tunnel has been run 500 feet and will be pushed to the bedded vein.

Manager F. Cook, of the Columbia C. M. Co. at Bingham, has resumed driving the Cunningham tunnel, which is to be extended 400 feet to cut the Alice vein 1025 feet from tunnel mouth. The company's shipments during 1902 included 350,000 pounds of copper, as compared with 115,000 pounds shipped in 1901, when the property was worked by leasers. A 75-ton lot of ore sent out last week brings the Columbia's December shipments to 100 tons.

Assays made of ore from the Peruvian of Little Cottonwood is reported by Manager Clays to contain 40% lead and eighty ounces in silver, besides gold and copper.

P. W. Ober, leasing the Hazel, adjoining Montezuma, near Bingham, has sunk an incline 15 feet on a vein carrying carbonate of lead and silver. A winze from the Snake (upper) tunnel of the Silver Hill claim of the New Red Wing group has followed an ore streak that has widened to 5 feet. One foot of the ore is galena, carrying 30% lead—the balance being of milling quality.

The Peruvian M. Co. reports a strike in its property in Little Cottonwood district. In the lower tunnel, 500 feet below the surface, a 6-foot vein has been opened up. Of this a foot is galena of shipping grade, while the rest contains milling values. Drifting on the vein is now in progress. Average samples assayed—lead, 20%; copper, 1.5%; silver, 38.9 ounces; gold, \$3.60. The Peruvian property is in Peruvian gulch off Little Cottonwood canyon below Alta.

At Bingham the Utah Con. (Highland Boy) M. Co.'s output of copper bullion last week was 352,800 pounds, from 3500 tons of ore, which is 3000 pounds more than for any previous week.

SUMMIT COUNTY.

Near Park City the Bogan shaft, now the Silver King Con., which is 600 feet deep, is to be enlarged to three compartments and will be sunk an additional 600 feet. Superintendent Keetley will install an air compressor and pumps.

The Anchor mill closed last week for repairs. Its capacity will be doubled. Superintendent M. C. Harrington of the Keystone, near Park City, reports the blacksmith shop, hoist and other buildings completed and the hoist in operation. The shaft is down 70 feet and sinking to the 600-foot mark.

The Record says an 18-inch strike of ore has been made in the Lone Pine, in the Snake Creek district, in the shaft, 85 feet down.

Ore carrying 25% copper is reported struck in the Great Western G. & C. Co.'s mines, in the Big Cottonwood district, which join those of the Daly-Judge and are over the divide from Park City.

WASHINGTON.

FERRY COUNTY.

The owners of the Malachite mine, near Keller, recently struck the ledge in No. 3 tunnel. Their No. 4 tunnel is in 307 feet, and they expect to reach the ledge in 22 feet.—The Iconoclast is temporarily closed down, pending the reorganization of the company.

The owners of placer claims on Mary Ann creek are getting in machinery as a preparation for active work next season. A reservoir has been built near the head of the creek by several of the claim owners. A pumping plant has been installed, by means of which water can be taken from a lake that is several feet lower than the placer grounds.

OKANOGAN COUNTY.

On Copper Mountain, near Bolster, the Mountain G. M. Co. has a tunnel in 800 feet, proving its property at a depth of nearly 400 feet.

WYOMING.

CARBON COUNTY.

It is reported the Copper Belt M. Co. has sold its property to C. R. Fishback and associates for \$250,000. This property consists of twelve claims in the Battle Lake district, adjoining the town of Dillon. These claims are patented and are the western extension of the Ferris-Haggerty and Osceola properties.

The breast of the Big Creek tunnel, in 850 feet, is in ore carrying galena, silver and copper. The same character of ore was found in the shaft, where at a depth of 140 feet the ore is 24 feet wide. The depth gained in the tunnel is 500 feet.

A company has been formed to develop Golden Edge claims, 3 miles southwest of Battle, in Baby Lake canyon.

Another strike of copper ore is reported in the new shaft on the Verde property south of Battle, showing a body of sulphides. At a depth of 70 feet the shaft has cut the foot wall. The crosscut in the Mount Zirkel from the 225-foot level has been run 25 feet, cutting the foot wall 14 feet from the shaft.

The buildings at the upper tunnel of the Doane Rambler mine, near Rambler, were destroyed by fire last week, including tunnel house, ore house, etc. The boilers and engine are not seriously damaged, though the air compressor is thought to be. The men in the workings got out safely. A ton of powder was lost also. The Battle Lake Tunnel site M. Co., owners of the mine, were having new machinery and buildings put up.

FREMONT COUNTY.

A. G. Paddock of South Pass sold his Rose mine to a company headed by A. Kendall of Rock Springs for \$50,000. The first payment of \$10,000 has been made.

FOREIGN.

BRITISH COLUMBIA.

The Annie vein of the Le Roi No. 2 at Rossland, which faulted at the 300-foot level, has again been located.

The minority interest in the Oro Denoro is reported bonded to S. Curtis and A. McNish of Rossland.

The Prospector says there have been during the past year 150 men working the paying placer mines on Wild Horse creek, near Fort Steele. During the season several tunnels were run to prospect the gravel overlying what is supposed to be the old channel of Wild Horse creek, and attempts were made to bottom the channel of the main creek by means of shafts, but were abandoned on account of water.

—The Nip and Tuck, owned by D. Griffith, is leased to a Chinese company. The gold obtained is coarse. The bedrock is hard and smooth, without crevices. The company are cutting a flume in bedrock, which will be completed by spring.—R. Dore, at the Cariboo, is running a tunnel to tap a channel on the west side of the creek. From the results obtained by a Chinese company on the east side of the creek it is supposed there is another channel parallel with the main creek.—During the years that placer mining has been conducted on Wild Horse the creek has been filled with tailings, which have been worked by a Chinese company by means of a bedrock flume.

Considerable work is being done on Boulder creek, near Atlin, this winter, in view of the weather conditions, says the Claim. In some cases drifts are being run in the creek bed, keeping in the pay where the summer's work ended. In others the pay is being followed in and under the benches. Timbering has to be done in every case. All the operators are sluicing the dirt as they take it out, and by the arrangements for sluicing they are encountering very little trouble from cold weather.—L. Yerke and partner are working on the company's ground, and near the intake Johnson and son are running a drift into the right-hand bench.—T. Rayl et al are drifting in the creek

bed.—Burgin, Hetland & Bartim, above Rayl, are following the pay into the bench by drift.—On the Weston property, bought by Stevens, Currie & Benton, a drift is being run into the right-hand bench in pay.—Norton brothers are working with four men on the Victoria group.—Pavey, Anderson, Deal & McNaughton are drifting on the Anderson property.—Symons & Pillar, on the former's ground, are drifting from the creek into the bench.

The past season's work at Lytton has proved that the Fraser river will pay to dredge. Twenty-eight ounces have been taken out in one day. Now dredges will be put in. Mr. White, chairman of the directors, is in charge of the work.

It is reported the Morning Star, a gold quartz property near Fairview will resume. The Morning Star and the Black Diamond are owned by S. Mangott and P. McEachern, of Fairview. They will sink another 100 feet on the Morning Star.

T. Conley and associates have leased the Canadian King mine at Erie. An incline shaft has been sunk to 288 feet and a total of 600 feet of development work done.

The tonnage for the past year of the Slocan and Slocan City mining divisions will amount to 26,000 tons, being about the same as for 1901. One-third of this was contributed from the dry ore mines. There are 300 men working in the vicinity of Sandon.

The Bosun, Payne, Wakefield and Hewett are making test shipments of zinc ore to Iola, Kan., and the Slocan Star and Ivanhoe propose doing the same. During the past year the largest shippers were the Arlington 3460 tons, American Boy 1092, Payne 1802, Whitewater 2962, Enterprise 1960, Rambler-Cariboo 4123, Ruth 825, Bosun 1190, Monitor 1136.

The Ruth, Whitewater, Last Chance and Noble Five are now closed. A few men are doing development work, getting out ore to pay running expenses. In McGuigan basin the Rambler-Cariboo is working forty men, having out its force one-half, and is shipping eighty tons per month. There is not enough water during winter to run the mill.

The Antoine is shipping seventy-five tons per month and working ten men. The Red Fox and the Washington have twelve men each and are shipping forty tons per month. The Silver Gleaner, near Bear lake, is another shipper. It has a showing of sulphurets and carbonate ore. The returns from one car gave \$3000. The Hope, adjoining the Ruth, is doing development and shipping two cars of carbonate per month. The Ivanhoe, owned by the Minnesota Silver Co., has been developing with twenty men, running the mill occasionally, and is making a zinc product. It has on hand 300 tons, but because of present prices is not shipping. The American Boy is shipping 100 tons per month and employing twenty men. It is shipping its ore over the Noble Five tramway and then out over the K. & S. railway. The Sunset, above Cody, has shipped 250 tons of ore since the rawhiding season of last winter. The management has decided to cease shipping and do only development work during the winter. They propose to build an aerial tramway in the spring.

G. Hughes is reported to have sold his fourth interest in the Idaho mines, near Sandon, for \$75,000 to the Scottish-Colonial Goldfields Co.

The Goldfinch claim, near Greenwood, is bonded to C. M. Fassett of Spokane, who has let a contract to sink 100 feet. Adjoining the Goldfinch are the Lancashire fraction and E. Pluribus Unum claims, under bond to parties represented by D. W. McVicar of Nelson. A prospect shaft on the former has been cleaned out and sinking resumed.

The stamp mill at the Wilcox mine, near Ymir, is in operation, reports Superintendent White.

The returns from the Arlington mine, near Erie, for November show 106 tons of ore and concentrates gave a return of \$4705.72. In addition a royalty of \$463.21 was obtained from sixty-three tons shipped by lease holders. The expenses of mining and developing through the same period were \$3317.41.

C. H. Wolf, a director of the Waterloo mine, in Camp McKinney, has arranged for a new hoist capable of working 600 feet. He says: "Since starting work in October we have opened a body of ore on the 150 level 4 feet wide. Average values from this level were \$81.86 for the first half of the drift and \$90.95 for the last half. The dump averages \$59.12. Two separate lots stored in the bins at the mill average \$34.31 and \$21.08. We will soon begin to sink the shaft another 100 feet and open the 250 level."

The Mines Exchange of Nelson reports that E. Cole of Portland, Or., has an option on a one-third interest in the Spotted Horse group near Ymir. The Standard Development Syndicate has

been formed to operate the Hunter V. mine, between Porcupine and Hidden creeks, consisting of the Hunter V. and Double Standard claims. The surface formation of the former claim consists almost entirely of calcite, nearly all of which carries a small value. Interspersed in it are pocket ore shoots of gold-bearing gneiss. Two carloads of ore were rawhided out last winter, and were reported to have returned a value of about \$26 per ton.

The Payne mine management is working two shifts getting out zinc ore for shipment to the Lanyon smelter of Iola, Kansas.

The Morning Star group, near Fairview, is sold to E. L. Simpson, J. Hogan and T. A. Beall of New York, for \$25,000.

At the Payne seventy men are working at the mine and two shifts are employed at the mill. The concentrator is milling zinc exclusively, sending out two cars daily, besides a weekly shipment of twenty tons silver and lead concentrates.

The Lucky Jim is leased to Goldsmith & Jefferies of Sandon.

In the Lardeau mining district the Northwestern Development Syndicate expects to have its small mill ready for operation by Feb. 1st. The aerial tramway to the Goldfinch claim has been completed.

The final payment on the Cholla group is made by the Imperial Syndicate to A. F. Rosenberger.

Revelstoke men have bought the Silver Dollar group, three claims and two fractions, about 200 acres.

The third payment on the Eva mine was made on the 10th inst. to A. F. Rosenberger by the Calumet & British Columbia Gold Mines, Ltd., \$10,000, a total of \$25,000 paid to date. The group is on Lexington mountain, 1½ mile from the town of Camborne, at the junction of Poole and Fish creeks. The formation in the vicinity is talcose and micaceous schist, at intervals resembling sandstone or quartzite. There are six main tunnels on the property, from which have been run numerous drifts. There are a number of smaller cuts and surface workings. The total length of the tunnel workings amounts to over 2000 feet. The management is figuring on a stamp mill.

C. W. Milne, chairman of the Rossland-Kootenay Co., says the Victory-Triumph mine on Sophie mountain will be reopened. The principal workings on the Victory-Triumph consists of a tunnel, giving an average of 250 feet of backs. This tunnel runs for 350 feet through an ore shoot, carrying gold-silver-copper values. Manager Thompson estimates that there are 20,000 tons of concentrating ore in sight. He will recommend to the company that a "high speed" gravitation stamp mill be installed—the concentrate shipped to the reduction works. The ore will concentrate six to one."

Stopping has begun at the Kootenay mine and shipping started, says C. W. Milne, of the Rossland-Kootenay Co. These shipments will be temporary. The ore will be sent to the Trail smelter, where tests will be made. This company is considering the building of a smelter.

It is reported that the Abe Lincoln mine on Deer Park mountain, near Rossland, will resume. Copper ore of good quality has been found on the Abe Lincoln, but the veins thus far have been stringers.

The Paystreak says seven men will be kept at work on the Sunset, near Sandon, all winter doing development. Ore has been taken out ready for shipment and reserves blocked out, but only enough rawhiding will be done to keep the trail open. J. Wolverton has bought A. Erickson's interest in the C. O. D. claim on Bear lake and development work is being done.

A contract for sinking a shaft 100 feet on the Gold Finch claim, near Greenwood, recently bonded by C. M. Fassett of Spokane, has been let to J. H. Griffin and P. Steffen.

At the Montreal & Boston C. Co.'s smelter at Boundary Falls the iron work of the new furnace is in place and the brickwork is being done. Superintendent Goodell says the second furnace will be blown in next week.

A snowslide struck the bunkhouse of the Molly Gibson mine, 10 miles from Lake Kootenai, Christmas night, wrecking the building, and it is reported ten men were killed.

C. M. Eyr has succeeded to the management of the Bullion Extraction Works at Silica, where the War Eagle and Center Star companies are experimenting with the concentration system they have evolved. The experiments are reported to be proceeding satisfactorily. Several additional agitating tanks are to be installed.

The Rossland Miner says New York men, represented by W. W. Hageman, have a two years' working bond on the Hungry Man property on Rover creek opposite Slocan Crossing. Machinery for

development ahead will be put in. The property has a vein opened up at several points by shafts and drifts. The ore is pyritic, carrying gold-copper values.

It is reported the Cobbledick dredge has closed a successful season on the Fraser river. This is the first to pay in British Columbia. The company proposes to increase operations next season. In Harper's camp, Cariboo, where hydraulic plants are operating, the expense is so heavy that although the ground yields \$1 per cubic yard it is too expensive to yield good profits. Manager Ward says the proposition is now being considered of using dredges on these properties. Last season Mr. Ward took out \$3000 a month, which little more than pays expenses.

KLONDIKE.

The geyser on fraction No. 3 on El Dorado creek has done much damage. The geyser, which broke out early in December, and which the Government succeeded in capping, has broken out anew and is sending a great volume of water all over the country. The glacier which has been formed from the geyser extends over an area of 3 miles and is increasing.

MEXICO.

CHIHUAHUA.

The La Luz G. M. Co. has begun operations at Maguarichic. A contract for a 200-foot tunnel has been let to connect with the old workings known as the San Francisco mine, and will be run on the San Jose vein. Men are taking out ore on the El Salto vein of the La Luz property. A contract for a tunnel to connect with this work will be let. On the adjoining property, the Sociedad y Anexas, a shaft has been sunk 185 feet on the La Vena vein. Three levels have been run on this vein from 20 to 100 feet each, and a crosscut from the 150-foot level has cut the San Jose vein, showing 2 feet of ore which assays \$200.

The concession granted to F. Arellano, M. Tamborrel and J. Urias for the establishment of two metallurgical works, one in Parral and the other in Jimenez, has been approved by the Mexican Congress. H. J. Clifford, manager of the Dragoon M. Co., says he will resume work on the Columbia mine at Terrazas next week.

At Terrazas the development work in the Shamrock has opened up a 2-foot vein of ore, which later widened to 5 feet.

On the Guadalupe, at a depth of 60 feet, F. McDonald says he found a flat vein that contains the same grade of ore as that found at greater depth in the old workings.

Dale Bros. & McDonald are working day and night shifts on the Wisconsin, adjoining the American, recently sold to Boston men.

SONORA.

The Cochise & Sonora M. Co., owning 500 pertenencias 25 miles southwest of Cos, the terminus of the Nacozari Railroad, has one shaft down 300 feet and another 200 feet.

The Mexican Hydraulic M. Co. is incorporated in Tombstone, Arizona, to work 20,000 pertenencias of placer ground in the district of Altar. The fields are known as the Cienega and Bonanza placers.

The Anglo-American G. & C. Co. is exploiting a gold-copper property of 200 pertenencias in the San Domingo mountains, south of Cananea, between Bacuachi and Baconoché. Four tunnels have been run in on the vein and show ore containing iron, copper, gold, carbonate of lead and zinc. The ore is said to run \$16 in gold and 6% copper. A three-compartment shaft is being sunk.

The Grand Central at Minas Prietas is prospecting several of its properties with a well-boring outfit. Each bucketful of dirt is assayed as the work progresses.

The report of Consul-General Barlow states that Sonora has the greatest amount of American capital invested in mining of any State in the Republic of Mexico—\$27,800,000. Chihuahua comes next with \$21,000,000. Coahuila shows the greatest total of American investments—\$48,700,000—of which \$37,800,000 are credited to the Mexican International Railway. Sonora comes next with \$37,500,000, of which, as stated above, more than \$27,000,000 are in mining enterprises.

The Cananea Co. has decreased its working force by 400. The company intends building 25 miles of railroad and a \$150,000 water system that will bring water from the head of the Sonora river to Cananea.

The Ruby G. & C. Co. is developing a property near Batamote, 40 miles southwest from Ortiz. G. W. Crowe is general manager. Sixty men employed. A good showing of ore is reported.

A Texas company, with B. Gibbs of Dallas as manager, has denounced 1200 pertenencias of the placer 22 miles from Magdalena, and 3 miles from the Sonora Railroad. The placer has 18 feet of gravel and is to be handled by a dry process.

Personal.

J. STEWART is superintendent Leland mine, Mohave county, Ariz.

ALGERNON DEL MAR of Los Angeles, Cal., is in San Francisco, Cal.

L. I. BLAKE of Lawrence, Kansas, has returned there from Denver, Colo.

E. B. RANDOLPH is superintendent the Italian mine in Lemhi county, Idaho.

BEN STANLEY REVETT has returned from San Francisco, Cal., to Denver, Colo.

J. H. PORTER, manager Fairview mine, Minersville, Cal., is in San Francisco, Cal.

J. S. EGGINGTON is superintendent of the Del Rey Oil Co., near Bakersfield, Cal.

J. F. PARKS, superintendent Kennedy mine, Jackson, Cal., is in San Francisco, Cal.

J. JOSEPH of San Francisco, Cal., mine owner of Tonopah, has gone to Tonopah, Nev.

W. THOMPSON, general manager of the Rossland-Kootenay Co., has gone to London, Eng.

E. L. WHITE of Victor, Colo., is appointed Stato Commissioner of Mines for Colorado.

SUPERINTENDENT J. BRAY of the New York and Nevada C. Co. at Ely, Nev., is in New York.

W. J. BELCHER, owner of the White Bear mine, near Downieville, Cal., is in Oakland, Cal.

W. S. EBERMAN, of the Oregon S. & R. Co., Sumpter, Or., has returned from Seattle, Wash.

J. H. SANBORN, of Denver, Colo., representing the Leyner Drill Co., is in San Francisco, Cal.

C. A. BUTTERS, E. M., is examining mining properties at Candelaria, Esmeralda Co., Nevada.

M. SAVAGE is superintendent of the Deep Canyon mine, near Last Chance, Placer county, Cal.

W. P. KETCHAM, superintendent Copper Bell mines, Clinton, Mont., has gone to Milwaukee, Wis.

MANAGER B. T. LLOYD of the Copper Mountain has returned to Salt Lake City, Utah, from the East.

S. E. RIGG, superintendent the McAlpin mine, near Groveland, Cal., has gone to Seattle, Wash.

MANAGER RADDATZ, the Honoring mine at Stockton, Utah, has returned from Salt Lake, Utah.

A. P. MALLON of the Anaconda C. M. Co. assay department at Anaconda, Mont., is in San Francisco, Cal.

D. R. WILLIAMS, superintendent of the Carisa mine, has returned to Tintic, Utah, from Salt Lake City, Utah.

T. GOODWIN is general manager the Republic & R. Co. smelters, at Salida, Colo., and at Leadville, Colo.

M. D. GAYLORD, superintendent American and Helen Rae mines, has returned to Nogal, N. M., from the East.

BERNARD MACDONALD has returned to Spokane, Wash., from Murray, Idaho, where he has mining interests.

E. W. MUELLER, manager the Oregon S. & R. Co. plant at Sumpter, Or., is in St. Joseph, Missouri, on a visit.

H. THORP, superintendent Hathaway placers, on Grouse creek, in Marshall Lake district, Idaho, is in Denver, Colo.

G. B. HALLORAN, superintendent Hollister interests in Thunder Mt. and Big Creek districts, Idaho, is in Boise, Idaho.

G. V. HOPKINS has resigned the management of the Bullion Extraction Works at Silica, B. C., being succeeded by C. M. Eyr.

THOS. RICKARD, of the firm of Harron, Rickard & McCone, has returned to San Francisco, Cal., from a visit to New York City.

R. WHINNERAH has resigned as superintendent of the Humphrey T. & M. Co.'s mill at Creede, Colo., and is in Denver, Colo.

J. KEEGAN has resigned the position of superintendent of the Mountain Con. mine of the Anaconda M. Co., Anaconda, Mont.

W. C. WALLER, E. E., of San Francisco, Cal., has gone to Tonopah, Nev., to look after the electric lighting installation there.

H. M. CROWTHER of the Blue Con. mine in Beaver county, Utah, has returned to Salt Lake City, Utah, from Arizona.

G. H. ROBINSON, consulting engineer for the Montana Ore Purchasing Co., Butte, Montana, has gone to New York on business connected with the Heinze interests.

G. K. KIMBALL, JR., manager the Old Town Con. M. Co. of Russell gulch, Gil-

pin county, Colo., has returned there from Pittsburgh, Pa.

H. A. GEISENDORFER has returned to California from Sumatra, and has gone to the Golden Eagle mine at Hayden Hill, Cal., as foreman.

W. H. MCCLINTOCK of the San Pedro Mines Co., Tuolumne county, Cal., has returned to San Francisco, Cal., from Phoenix, Arizona.

W. L. COBB, of the Wright-Gilman Co., San Francisco, Cal., has returned from Sonora, Mexico, where he has been examining mining properties.

U. B. CURTIS has resigned as manager Tonopah Fraction M. Co. at Butler, Nev., to devote his time to other properties in Tonopah in which he is interested.

J. QUINN, former superintendent the Sampson mine, Bingham, Utah, goes to Shasta county, Cal., to have charge of the Western Exploration Co.'s Gold Peak mines.

JOHN K. MACKENZIE of Dickman, Mackenzie & Potter, mining engineers of Chicago, has returned from Mexico. Mr. Mackenzie will be at Gilt Edge, Montana, next week.

R. N. DICKMAN of Dickman, Mackenzie & Potter of Chicago has returned to Chicago from Europe, where he has been for nine months examining mining properties of an American company.

C. H. LINDLEY, of San Francisco, Cal., has returned home from Washington, D. C., where he has argued the case of the Kennedy vs. Argonaut M. Co. before the United States Supreme Court.

W. F. DETERT, president the Argonaut G. M. Co., Jackson, Cal., has returned from Washington, D. C., where he attended the re-argument of the Argonaut-Kennedy case before the Supreme Court of the United States.

GEORGE J. ROCKWELL, who for many years has been connected with the Allis-Chalmers Co. in Chicago as metallurgist and salesman, has been transferred to Denver, Colo., to be associated with Robert J. Cory, manager of their office in that city.

Obituary.

J. W. YOCUM, president of the Black Swan M. & M. Co., near Salina, Boulder county, Colo., died in Reading, Pa., Dec. 23, 1902.

PROF. P. H. VANDIEST, the metallurgist and geologist, died of heart failure at the home of his son in San Luis, Colo., on Christmas day. Mr. Van Diest was born in Edam, Holland, and came to Colorado in 1872. For a time he held the chair of metallurgy in the State School of Mines. He was the discoverer of a new telluride in this State which bears his name, diestite. In addition to the son he leaves four daughters.

Books Received.

"The How and Why of Electricity," by Charles Tripler Child, published by the Electrical Review Publishing Co. of New York, N. Y., is an attractive and instructive little volume for the non-technical reader. It contains 127 pages, and numerous drawings. While not pretending to tell what electricity is, it does tell of its properties, how generated, handled, controlled, measured and set to work. Price \$1.

"A Text Book of Quantitative Chemical Analysis" is the title of a 600-page, octavo, volume, by Frank Julian. It is a thorough dissertation of the subject, with many illustrations of appliances and methods. It is intended for the aid of students having a fair acquaintance with the elements of general chemistry. In the various chapters of the work the general principles of the art are described. Directions are given in detail. In part 3 is considered the analytical behavior of a number of articles of commercial importance. More prominence than is usual in such treatises on quantitative analysis has been accorded the principles underlying the methods of analysis. Price, \$6 net. The Ramsey Pub. Co., St. Paul, Minn.

Catalogues Received.

"Wire Rope Tramways" is the title to the latest publication of A. Leschen & Sons, of St. Louis, Mo. The booklet is handsomely illustrated, showing the operation of their rope tramways under many conditions. These tramways are automatic—of the double rope type, reducing the labor of handling materials to the minimum. The buckets are of several patterns, but all are so arranged that they cannot tip over of themselves, though requiring no locking up to keep upright. The book will prove of interest to all who have difficult problems in transportation in mountainous regions. Sent on application.

Commercial Paragraphs.

WADE & WADE now occupy their new assaying establishment 318 E. First St., Los Angeles, Cal., a building erected by themselves on their own ground with special reference to the requirements of their business.

THE Chicago House Wrecking Co. of Chicago will erect an addition to their shops of 135x435 feet. This company do considerable business in second-hand machinery, buying and selling in every part of the world. They report that their business with mines has increased greatly of late.

THE Smooth-On Manufacturing Co. writes that while a Smooth-On gasket connection may take a little longer time to make than when using an ordinary steam packing, when once made it will be more durable and seems to improve with age. They say that difficult flanged connections can easily be made with Smooth-On, as it is applied in a plastic state and adapts itself to the flanged faces whether parallel or not. They say that it has been tested to 1500° F. and withstood 400 pounds steam pressure without any injury. "Smooth-On when hard expands and contracts the same as iron, keeping the joint tight at all temperatures, and it will withstand steam, water, fire or oil." Their sixty-page illustrated book, which gives full information regarding this subject, will be sent to any address.

THE J. H. Montgomery Machinery Co. of Denver, Colo., report that they have a rush to fill all orders for their wire rope tramways. They have orders for four at the present time on their books; one of 100 tons capacity per day for Baker City, Or.; one of fifty tons capacity in ten hours for the Silver King mine at Dillon, Colo., this being the second tramway ordered by this company, they having erected one on another one of their mines near there last year. They are also building one of four tons per hour capacity for Montezuma, Mex., and one for Fairbanks, Morse & Co., to be erected in Arizona and to have a capacity of fifty tons in ten hours. They write they have also hooked an order for a set of their 14x27-inch duplex swing frame rolls fitted with Latrobe shells, and other machinery for a small concentrating plant near Cook's Peak, New Mexico.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

THE CONSTRUCTION OF CHIMNEYS, WALLS, ETC.—No. 716,446. Dec. 23, 1902. J. F. Lyman, South San Francisco, Cal. This invention relates to an apparatus for the construction of chimneys, walls and like structures with interior continuous tubes to form flues or other conduits or passages. It consists of strips or plates of material, capable of being closed to make an exterior form, means for rigidly locking them in their closed position, centrally located terra cotta or earthenware tubes, and means for maintaining said tubes in alignment with a smooth interior surface, while concrete is tamped about them and within the exterior casing to form the structure.

AIR TEMPERATURE REGULATING AND PURIFYING DEVICES—No. 716,380. Dec. 23, 1902. L. E. Clawson, S. N. Francisco, Cal. This invention is designed to purify the air within a room. It consists in the combination in an organized apparatus for regulating the temperature of and purifying the air of a horizontally disposed box having within it two walls forming a tortuous air passage, the upper of said walls formed with a series of connecting curves of regular formation and extending in the direction of the length of the box, and the lower wall being formed substantially angular in longitudinal section with openings at the bases of the angles in which the said curves are having within the upper wall; gratings in the upper portion of the curves of said upper wall, adapted to receive a cooling medium; air-forcing mechanism connected to one end of the tortuous passage and a discharge and conductor at the opposite end of the passage.

CARBURETORS FOR EXPLOSIVE ENGINES.—No. 716,573. Dec. 23, 1902. C. N. Nels, Palo Alto, Cal. This invention relates to an apparatus which is especially designed for carbureting or c'arging air with hydrocarbon vapor in such proportions as to render it explosive, and it is especially designed for use upon motor cycles, automobiles and like machines or engines. It consists of a box having within it spaced conical diaphragms forming a partition between the top and bottom. There is a means for delivering the liquid upon the apex of the lower diaphragm, and vertically disposed open ended tubes pass through the periphery of the diaphragm and have openings communicating with the space into which the liquid is admitted. There is a chamber located above the cone into which the upper ends of the tubes discharge, and said chamber has openings from the lower part into the tubes whereby any liquid carried into the chamber may be returned to the tubes.

OIL BURNING FURNACE ATTACHMENT.—No. 716,488. Dec. 23, 1902. J. R. Scott, Oakland, Cal. One-half assigned to E. L. Cook, Diamond Springs, Cal. This invention is designed for furnaces in which oil is employed as a fuel. It consists in a means for injecting a body of steam or air, or both, to meet the products of combustion before the escape through the chimney of the furnace. It consists in combination with an oil-burning furnace of burner jets discharging into the front and the escape flue or chimney of a jet tube to conduct air or steam, said tube discharging into the chimney and against the outflow of the products of combustion and a cock to regulate the current thus introduced.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR WEEK ENDING DECEMBER 23, 1902.

716,359.—PRESS—R. T. Allen, Fernando, Cal.
716,380.—STUMP PULLER—W. Anderson, Ballard, Wash.
716,381.—AIR PURIFIER—L. E. Clawson, S. F.
716,404.—HOOK AND EYE—Gastren & Cortelyou, Los Angeles, Cal.
716,439.—PUMP—F. Heil, Santa Ana, Cal.
716,514.—SCALE—G. Hoepner, S. F.
716,710.—MEASURING DEVICE—P. Hofman, Los Angeles, Cal.
716,444.—MOP HEAD—J. C. Look, Tudor, Cal.
716,446.—CHIMNEYS, ETC.—J. F. Lyman, South San Francisco, Cal.
716,741.—EXCAVATOR—C. C. McBride, Redding, Cal.
716,573.—CARBURETOR—C. N. Nels, Palo Alto, Cal.
716,468.—SWAGE—E. North, Los Angeles, Cal.
716,483.—CONDUIT—A. C. Ryan, Cherokee, Cal.
716,486.—OIL BURNER—J. R. Scott, Oakland, Cal.
716,650.—WATER MOTOR—Wheeler & Besse, Seattle, Wash.

Latest Market Reports.

SAN FRANCISCO, Dec. 31, 1902.

METALS.

SILVER.—Per oz., Troy: London, 22 $\frac{1}{2}$ d (standard ounce, 925 fine); New York, bar silver, 48c, refined (1000 fine); San Francisco, 48c; Mexican dollars, 38 @39c San Francisco, 38c New York.

COPPER.—New York: Standard, \$11.00; Lake, 1 to 3 casks, \$11.62 $\frac{1}{2}$; carload lots, \$11.30; Electrolytic, 1 to 3 casks, \$11.50; carload lots, \$11.25; Casting, 1 to 3 casks, \$11.35; carload lots, \$11.10. San Francisco: \$14.00. Mill copper plates, \$17.00; bars, 18@24c. London: £52 6s 3d spot per ton.

LEAD.—New York, \$4.12 $\frac{1}{2}$; Salt Lake City, \$3.50; St. Louis, \$4.00; San Francisco \$4.50, carload lots; 4 $\frac{1}{2}$ c 1000 to 4000 lbs.; pipe 5 $\frac{1}{2}$, sheet 6, bar 5 $\frac{1}{2}$ c; pig, \$4.75. London: £10 16s 3d per ton.

SPELTHER.—New York, \$4.70; St. Louis, \$4.50; London, £19 17s 6d per ton; San Francisco, ton lots, 6 $\frac{1}{2}$ c; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9 $\frac{1}{2}$ c; Hallett's, 8 $\frac{1}{2}$ c; San Francisco, 1000-lb. lots, 10c; 300 to 500 lbs., 11c; 100-lb. lots, 13@15c.

TIN.—New York, pig, \$25.95@26.00; San Francisco, ton lots, 27c; 500 lbs., 27c; 200 lbs., 27 $\frac{1}{2}$ c; less, 28c; bar tin, 32 $\frac{1}{2}$ c. London, £120 15s spot.

PLATINUM.—San Francisco, crude, \$18.00 per oz.; New York, ingot, \$19.00 per Troy oz. Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, \$45.50@46.50; large lots; London, £8 15s; San Francisco, local, \$46.00 per flask of 7 $\frac{1}{2}$ lbs.; Denver, \$49.50. Export, \$43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6 $\frac{1}{2}$ c; extra, 17 $\frac{1}{2}$ c; genuine, 35c; Eclipse, 37 $\frac{1}{2}$ c.

ALUMINUM.—New York, No. 1, 99 $\frac{1}{2}$ ¢ pure ingots, 35c; No. 2, 90 $\frac{1}{2}$ ¢, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 18c; San Francisco, Plumbers', 100-lb. lots, 15.10c.

NICKEL.—New York, 50@60c per lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$24.25; gray forge, \$21.15; San Francisco, bar, 3c per lb., 3 $\frac{1}{2}$ c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$28.00@30.00; open hearth billets, \$32@34.00; San Francisco, bar, 7c to 12c per lb.

Black blasting powder in carload lots, minimum car 728 kg., \$1.50 per keg; less car lots, \$2 per keg.

CAPS.—3x, \$5.50 per 1000; 4x, \$6.50; 5x, \$8; Lion, \$9, in lots not less than 1000.

FUSE.—Triple tape, \$3.60 per 1000 feet; double tape, \$3.00; single tape, \$2.65; Hemp, \$2.10; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10 $\frac{1}{2}$ c per set; 14 oz., 40s., 9 $\frac{1}{2}$ c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 25@26c per lb.; carloads, 24@24 $\frac{1}{2}$ c; in 10-lb. tins, 35c; sulphuric acid, in carboys, 66 $\frac{2}{3}$ B, 2c per lb.; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 24@30c per lb.; blue vitriol, 5 $\frac{1}{2}$ @6 $\frac{1}{2}$ c per lb.; borax, concentrated, 7@8c per lb.; chloride of potash, 12@13c; roll sulphur, 3c; alum, \$2.00@2.25; flour sulphur, French, 3 $\frac{1}{2}$ @3 $\frac{1}{2}$ c; California refined, 2@2 $\frac{1}{2}$ c; nitric acid, in carboys, 8c per lb.; caustic soda, in drums, 3@4c per lb.; Cal. s. soda, bbls., \$1.25 @1.50 per 100 lbs.; sds., \$1.05; chloride of lime, spot, \$2.50@2.60; nitrate of potash, in bbls, 8c; caustic potash, 10c in 40-lb. tins; sulphide of iron, 9c per lb.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.50; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lots, Eastern and foreign: Wallsend, \$6.50; Brymho, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8; Cumberland, \$12; Cannel, \$9.00; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13 in sacks; Sunnyside, \$8.50, long ton.

OILS.—Linseed, boiled, bbl., 54c; cs., 59c; raw, bbl., 52c; cs., 57c; lots of 5 bbls., 1c less; Lucol oil, hhd., 48c; cs., 53c; raw, bbl., 46c; cs., 51c. Kerosene—Pearl, per gal., 22 $\frac{1}{2}$ c; Astral, 22 $\frac{1}{2}$ c; Star, 22 $\frac{1}{2}$ c; Extra Star, 24c; Eocene, 23 $\frac{1}{2}$ c; Elaine, 26 $\frac{1}{2}$ c; Water White, in bulk, 16c; Mineral Seal, iron bbls., 18c; wooden bbls., 20c; cs., 24c; Mineral Sperm, cs., 26 $\frac{1}{2}$ c; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23 $\frac{1}{2}$ c; 86° Gasoline, bulk, 21c; do., cs., 27 $\frac{1}{2}$ c; 63° Naphtha or Benzine, deodorized, in bulk, per gal., 16c; do., in cs., 22 $\frac{1}{2}$ c; Lard Oil, No. 1 bbl., 95c; cs., \$1.00; Neatsfoot Oil, bbl., 70c; cs., 75c; No. 1 bbl., 55@57 $\frac{1}{2}$ c; cs., 57 $\frac{1}{2}$ @60c; Sperm, crude, 50@60c; Natural White, 65c; Bleached do, 70c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: Five tons and over at one purchase, per lb., 6c; 1 ton and less than 5 tons, per lb., 6 $\frac{1}{2}$ c; 500 lbs. and less than 1 ton, per lb., 7c; less than 500 lbs., per lb., 7 $\frac{1}{2}$ c; in 25-lb. tin pails, 4c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, 2 $\frac{1}{2}$ c per lb. above keg price. Dry Lead—in bbls., 1 ton and over, 6c; do. in kegs, 6 $\frac{1}{2}$ c.

RED LEAD AND LITHARGE.—One ton and over at one purchase, per lb., 6c; 500 lbs. and less than 1 ton, per lb., 6 $\frac{1}{2}$ c; less than 500 lbs., 7c.

ASSAY LITHARGE.—Per lb., 8 $\frac{1}{2}$ c.

BISMUTH.—Subnitrate, per lb., \$1.60.

BONE ASH.—4c per lb.

BORAX.—Crystal, 7c; calcined, 25c.

CHROMIUM.—(90% and over) per lb., \$1.25.

COPPER.—Carbonate, 20c; Red oxide, 60c.

MANGANESE.—(90% and over) per lb., \$1.25.

MERCURY.—Bichloride, per lb., 90c.

MOLYBDENUM.—25c per gramme; 1000 grammes—2 $\frac{1}{2}$ lbs.

PHOSPHORUS.—(American) per lb., 80c.

SILVER.—Chloride, per oz., 75c; nitrate, 55c.

SODIUM.—Metal, per lb., \$1.00.

URANIUM.—Oxide, per lb., \$3.50.

ZINC.—Metallic, chemically pure, per lb., 50c.

ZINC.—Dust, per lb., 10c.

ZINC.—Sulphate, per lb., .04c.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

A Typical California Enterprise.

In El Dorado county, California, the gold belt is wider than in the counties farther south, and it embraces a more diversified geological field. In the neighborhood of Placerville, however, the mines bear a striking resemblance to some of those about Quartz and Stent, in Tuolumne county. In fact, these two sections bear a greater similarity than any two other portions of the mother lode. A marked difference is noticed in the topography of the two sections, however; the country about Stent and Quartz being relatively flat, while north of Placerville the American river has cut deep into the slates and schists. The River Hill mine near Placerville affords a typical illustration of the character of the mines of the vicinity. The formation is slate, serpentine and dolomitic material, with gold-bearing quartz. It is at present worked through a shaft and is equipped with a modern 20-stamp mill, illustrations of exterior and interior of which are shown herewith. A crosscut tunnel is being driven 2500 feet to the vein on the 900 level. When this is completed a new and larger mill will be built at the mouth of the tunnel. The third illustration shows a section of the vein in the face of a drift. T. Clark of Placerville is manager.

The Vein in River Hill Mine, Near Placerville, Cal.

At the present session of the California Legislature a bill will be introduced creating the office of mine inspector for the State of California. Several attempts have heretofore been made to have this office created, but each time it has met with strong opposition, mostly from those having no personal interest either for or against the bill. The reason for this opposition probably lies not so much in the fact that those voting against the proposed bill know little or nothing of the duties of a mine inspector,

shall not be done in their absence. In case of any material change in policy or method in mining, the change must be made without waiting to consult the inspector or anyone else. Most mine superintendents in California are accustomed to going underground every day, each one of them acting as his own inspector, and in a time of unusual danger they will usually be found "in the thick of it," doing all

things in the twentieth century, prolific in discovered possibilities, give promise of this century's achievements outdoing those of the last one. In geology, which carries the idea of illimitable time; in astronomy, which conveys the idea of illimitable space; in chemistry, which carries the idea of illimitable subdivision and creation; in electricity, which almost justifies the idea of illimitable energy; in metallurgy, which includes the idea of increased underlying profit; in every department of science (which is organized knowledge) and art (which is applied science) is shown great advances—promise of further unfolding in this great constant history of the earth, a tremendous life history, steadily progressing toward ultimate completion.

SEVERAL of the largest mining companies of the Cœur d'Alene district, Idaho, have refused to pay taxes on their mines. The taxes upon improvements they have always paid, but it is the assessment of the mines themselves that they are combatting, and they will endeavor to have the law declared unconstitutional. The mines of that section have had, it would seem, more than their share of hardship already in the way of labor troubles, with low and lower prices for their product, and now that the expense of mining is increasing rather than diminishing, and other conditions give little promise of improvement, this taxation on property of uncertain and always lessening value looks something like the "last straw to break the camel's back." The towns of the district were built up wholly as a result of mining operations there, and were all the mines to close the towns would soon be nothing but a memory. It seems not only unjust, but unwise on the part of the local government to attempt this sort of extortion at a time when conditions affecting the prosperity of the

River Hill 20-Stamp Mill, El Dorado Co., Cal.

Interior River Hill Mill, El Dorado Co., Cal.

tor, or whether or not the creation of such an office would prove beneficial to the mining industry or the miners, as in a desire to have no additional political offices created. Theoretically, the office of mine inspector is all right, but that it practically proves a direct benefit is less apparent. The history of mining in California does not indicate that much would have been gained by the miners had there been a mine inspector in past years. The mines generally are of a character requiring skillful handling, and this proves a better present safeguard than any number of inspectors, who dictate what shall or

any one could do. Such men do not require a slide rule and a code of regulations to know what should be done.

THE new year is signalized in science by some notable advances in mining and scientific progress, prominent among which are the announced ability to produce cyanogen from the atmosphere, the transmission of wireless messages across the Atlantic, and telegraphic communication with Hawaii in the mid-Pacific. The impossible is being limited to that which is not yet possible, and the two years in the

mines of the entire district are so unsatisfactory.

IN the issue of the MINING AND SCIENTIFIC PRESS January 17 will begin the publication of an article by Dana Harmon, of San Francisco, Cal., on "Stamp Milling and Amalgamation of Free Gold Ores," illustrated with a number of carefully drawn sketches. This is a matter that interests every mill man and mine superintendent engaged in gold mining, and the subject is handled in a masterly and thoroughly practical manner by Mr. Harmon, who has had a wide and successful experience in milling gold ores.

The Precious Metal Output for 1902.

The preliminary figures for the output of precious metals in the United States in 1902 have been received from Director of the Mint George E. Roberts. The gold output shows an increase for the year of \$2,186,370, and silver a net increase of \$3,352,084. Following is the estimated production by States:

States and Territories.....	Gold Value.	Silver Value.
Alabama.....	\$ 2,873	\$ 5,000
Alaska.....	7,823,793	30,061
Arizona.....	4,155,099	1,680,100
California.....	17,124,941	480,793
Colorado.....	27,502,429	9,085,714
Georgia.....	102,388	445
Idaho.....	2,067,183	3,180,000
Maryland.....	2,956	2
Michigan.....	30,800	42,930
Montana.....	4,134,365	6,890,000
Nevada.....	3,514,212	2,120,000
New Mexico.....	688,400	298,602
North Carolina.....	91,783	11,498
Oregon.....	1,860,465	63,600
South Carolina.....	347,928	152
South Dakota.....	7,398,057	182,373
Tennessee.....	145	
Texas.....	600	250,357
Utah.....	3,720,930	6,360,000
Virginia.....	4,444	273
Washington.....	434,100	360,400
Wyoming.....	45,230	2,756
Totals.....	\$81,053,121	\$31,045,056
Klondike.....	14,562,101	91,768
Nome (including Alaska).....	5,023,256	9,540

A comparative study of production for the past three years shows a net gain over 1900 of about

\$3,500,000, and over 1901 of about \$640,000. The rapid depreciation of silver has undoubtedly helped to reduce the output by many hundreds of thousands of dollars.

Although the output of Alaska in 1902 exceeded that of 1901 by \$119,000, it still lacked about \$348,000 of reaching the output of 1900. Colorado in 1900 produced \$28,829,400, and in 1901 statistics showed a production of \$29,000,000. The year 1902 shows \$28,829,400, or a loss of \$170,600. California shows a substantial gain—\$1,308,741 over 1900 and \$1,294,941 over 1901. Arizona shows a slight gain over the two previous years. Nevada shows a gain of \$500,000 in gold, and South Dakota gains \$796,257 in gold production. All producing States show some change, but those above mentioned are the most important and noticeable. Official and exact reports will soon be issued, but no considerable change can be anticipated from the figures above given.

Chlorination of Gold Ores in California.

In the chlorination process, as practiced in California, the ore, consisting either of the concentrates from a single mine or a mixed concentrate from several mines, is dumped into the hopper of a reverberatory furnace containing from 4% to 10% moisture. Some of these furnaces have mechanical stirrers. It receives no preliminary treatment. The fuel is either wood or crude petroleum. Six months' experience at the Sutter Creek, Amador county, Cal., reduction works has demonstrated the great advantage of oil over wood for use in reverberatory furnaces. The ore is raked forward from one section of the furnace to the next. As soon as that portion of the hearth immediately beneath the hopper is made vacant by removal of the previous charge, another fresh charge takes its place, to be in turn moved forward when the charge preceding it has been moved another step ahead. The furnace remains very hot after the raising of the heat on a charge of ore about to be withdrawn, and this heat is sufficient to dry the raw ore on the first hearth, ignite it on the second and to partially roast it on the third. When the semi-roasted ore reaches the last section of the furnace—that nearest the burners—the oil is ignited by means of a bunch of oiled waste tied to the end of a long iron rod, which is inserted through one of the doors. Steam is kept up in a small boiler, under which coal is burned. This also keeps the oil in a fluid condition for rapid and easy flow. The oil is pumped to the burner and an intense flame—though one which is always under perfect control—results. The dead roast is usually accomplished in from fifteen to twenty minutes, after the charge has reached the last hearth, when the oil is shut off; but, as previously stated, the furnace continues to glow until nearly time to turn on the high heat again. The work has never been so satisfactorily and so perfectly done by means of wood. Some ores require the addition of salt in the furnace to chloridize certain elements, which would otherwise absorb a large amount of chlorine when the charge comes to be gassed. As the amount of silver in the California concentrates is usually very low, no particular effort is made to save that metal.

The means for determining the condition of the roasted pulp are various. Kustel, in his work on chlorination, suggests that a rapid method is to throw a small quantity of the roasted ore into water and then plunge a bright iron rod into the water. If sulphates remain in the ore the surface of the iron will become darkened, and the ore must receive a further roasting. This is said by Rose, in his work on "Gold," to be an unsatisfactory test with some ores, as with some the presence of sulphate of iron would not be detected in this way. He suggests a more trustworthy and equally simple test, which is to throw a little of the roasted ore in water and then add a few drops of barium chloride, when a white cloud (barium sulphate) will form, indicating the presence of soluble sulphates.

When the ore is determined to have reached the stage known as "dead roast," that is, when no more sulphates remain undecomposed, it is withdrawn from the furnace, dropping through a trap in the floor and falls into a steel car standing in a pit beneath. The car when filled is wheeled to the cooling

floor and dumped and the pulp spread out, when a stream of water from a hose is turned on it for a few minutes. When the ore has been dampened sufficiently it is charged into a wooden tank, the interior of which is usually painted with a preparation of paraffine, and which is provided with a false bottom.

The false bottoms are much the same everywhere, being made with graduated sizes of coarse to fine gravel, the whole resting on a canvas floor and being covered with an open floor of shovelling boards. The damp pulp is usually thrown onto a screen, which is shaken to make the ore fall as lightly as possible. When the tank is filled to 4 or 5 inches of the top a folded gunny sack is laid on the surface of the charge and the cover of the tank suspended from the timbers overhead is lowered by means of chain blocks and placed in proper position and luted on. At the Angels chlorination works, the largest in California, the tanks are girdled by an annular trough partly filled with water, and the covers are provided with a flange-like downward projection which fits into the water channel of the tank forming an air-tight joint. This has its advantage over the luting process.

Chlorine gas is evolved from a mixture of 100 pounds of salt and ninety pounds of manganese oxide, by means of sulphuric acid in leaden generators. Acid is added until the charge ceases to evolve gas. The chlorine passes along pipes and is conducted underneath the tanks into the bottom of the charge, and slowly ascends through it. The appearance of the gas at the surface of the charge is detected by applying a bottle of ammonia to a small hole in the cover of the tank, which is plugged excepting when the test is being made. If the chlorine gas has ascended through the charge to the surface a dense cloud of ammonium chloride forms. When this occurs the gas is shut off from this particular tank, and the charge allowed to stand a variable number of hours, determined by the experience with the material being treated. At the proper time a stream of water is turned into the tank through an opening provided for the purpose, the water falling upon the folded gunny sack which had been placed there. This has a tendency to prevent the formation of channels in the charge, or to cause strata of slimes to accumulate which would retard percolation. When the water reaches about 3 inches above the surface of the charge, a valve beneath is opened (though at some works the water is allowed to stand for some time on the charge) and the liquor drawn off to the precipitating vat. When a large amount of gold solution has been collected in a vat, a solution of iron sulphate is poured into it and dense clouds of black precipitate appear. The liquid is permitted to settle and is tested from time to time until the merest trace of gold remains in the solution when it is discharged.

If the ores contain much copper the solution is run into a large tank in which is a quantity of wrought iron scrap, tin scrap, etc., and the copper contained in the solution is recovered as cement copper. The gold tanks are decanted, the precipitate collected, dried, and mixed with suitable fluxes is melted into bars. If care be taken in the melting, all dross being removed, a high grade of gold results. Although there are a number of furnaces in California where this method of treating vanner tailings and canvas plant slimes is in use, none of them have been able to introduce any marked feature in the way of economy of handling materials, as in large cyanide plants, but this is due, no doubt, to the restricted supply of sulphurets. Few of the furnaces burning wood have over three and a half tons daily capacity and none burning oil over seven, and as the greatest number of furnaces in operation in any one plant does not exceed five (that of the Utica mine at Angels, Calaveras county), it is seen that the industry is necessarily conducted on a limited scale.

Barrel chlorination is not practiced in California at all, though with cheap power usually available in most mining districts its introduction would soon displace the present process.

CONSOLIDATION and merging goes on in mining operations in accordance with the present general law of business concentration, the reduction of expense and the elimination of waste.

CONCENTRATES.

A UNITED STATES PATENT may issue covering both a quartz and a placer claim.

THE best grades of Missouri and Kansas zincblende, it is claimed, contain about 60% zinc.

HEAVY pyritic ores require a steeper grade on mill plates than quartz ores. A grade of $1\frac{1}{2}$ inches per foot is normal.

THE statement that 60% copper matte is made from raw ore with a single smelting may be taken with some allowance.

PETZITE is telluride of silver, in which the silver is often partly replaced by gold. It occurs in California pocket mines.

THE presence of iron in solution in water is denoted when, upon the addition of one drop of ferro-cyanide of potassium, a blue color appears.

BEACH MINING is still carried on in a few places on the Pacific coast south of Alaska, but it is the least important kind of mining now practiced in the west.

FOR some unexplained reason a number of wires twisted into the form of the regulation cable has not the tensile strength of the aggregate of the individual wires.

WULFENITE is a soft yellow mineral (molybdate of lead) usually occurring in tabular crystals. Wolframite is a hard black mineral, a tungstate of iron and manganese.

THE purest gold obtainable has a tensile strength of 14,000 pounds per square inch. Gold containing one part in 2000 of bismuth can almost be crumbled in the fingers.

A CAREFUL study of the various rocks and material generally found in gravel channels will give a very fair idea of the character of the country through which the stream has passed.

A MINE near Garland, Colo., has the distinction of being what is probably the highest mine in the United States. It is at an altitude of 14,400 feet near the summit of the Sierra Blanca.

"PROPYLITE" is obsolete. It was a name given by Zirkel and Stache to certain rocks of Washoe district, Nevada, which later investigators have determined to be altered hornblende andesite.

WHERE placer locations are taken up on land previously surveyed by the Government, and conform to the legal subdivisions as nearly as possible, no further survey or plat shall be required.

EVERY stamp mill should be so arranged that at least one battery can be employed separately in making test runs on rock from various parts of the mine, independently of the balance of the mill.

THE capacity of a blast furnace is largely increased by employing hot blast. Other considerations in capacity are fusibility of the ore, quantity of flux required and the pressure and volume of the blast.

THE DIRECTION of ventilation between mine shafts that are connected underground sometimes changes with the seasons. A shaft that is upcast in summer becomes downcast in winter, or vice versa.

THERE are no so-called pyritic smelters in operation in the United States, so far as Concentrates is aware, where some carbonaceous fuel (usually coke) is not employed. It is essentially a "partial-pyritic" smelting.

THE best treatment amalgamating plates can receive is a good coat of gold amalgam. This cannot be obtained where low-grade gold ore is being milled and where the plates are scraped twice a month with steel chisels.

TO TEST sulphate of lime (gypsum), place in a test tube about 2 inches of the water and then add a little barium chloride: If a white precipitate is formed, and it will not be redissolved when you add a little nitric acid, sulphate of lime is present.

IT is a wise plan to have one man handle most of the powder in a mine employing a large number of men, as where the boxes are open to every one on shift it has been shown that the proportion of accidents from premature explosion is of more frequent occurrence.

IT HAS been stated that battery water at a temperature of 52° F. gives the best results in amalgamation of gold ores. A series of experiments were made at the Homestake mills, South Dakota, several years since to determine this point and the above announcement was the result.

TO ASCERTAIN whether water contains carbonic acid,

take a small quantity in a test tube and add a few drops of lime water. If carbonic acid be present the water will become milky (calcium carbonate), which, upon the addition of a few drops of hydrochloric acid, will again become clear.

GOLD occurs associated with iron sulphide (pyrite) in the form of invisible plates and grains, in those which are visible and in a few rare instances in masses as large as wheat grains or larger. An instance of the latter character is found in the Gambetta mine, Grub Gulch, Madera county, Cal.

THERE are those who still claim hand feeding in a stamp mill is superior to machine automatic feeding. This may be. But the man who has the intelligence to feed a stamp battery with a shovel better than it can be done by an automatic feeder is worth more to his employer doing something else.

EVERY well-managed quartz mill should have an automatic tailings sampler. It is unsatisfactory to take samples with a tin cup from the lower edge of a plate. The slightest touch to the plate is likely to salt the sample to such an extent as to render it worthless. There are several kinds of automatic samplers.

IN WORKING low-grade ores, the best modern practice is to employ low, quick discharge, large capacity, and do all the amalgamating outside the battery. Some feed quicksilver into the battery, but have no inside plates, and others feed all quicksilver outside. A mill man should adopt the practice which produces the best results.

TO TEST magnesia, fill a test tube one-third full of the water; hold it with the tube holder and bring it to a boil over the spirit lamp; then add a very few crystals of ammonia carbonate and a little soda phosphate. If magnesia is present, it will form a white precipitate; but as it may not do so at once, it is best to set it in the rack for a few minutes.

THE advisability of working mines single-handed or double-handed has been frequently discussed for half a century and there is a wide difference in opinion on the subject; but, on the whole, those who favor the single-handed system seem to have some advantages on their side. Doubtless the percentage of good double-handed strikers is greater than of good single-handed strikers.

THE AMOUNT of water used in a 5-stamp battery varies from $1\frac{1}{2}$ to $6\frac{1}{2}$ gallons per minute per stamp. In some California mills, where water is scarce, the least possible amount is employed. From 1000 to 2500 gallons of water are required to treat one ton of ordinary gold rock. The character of the ore and the coarseness of crushing must determine the amount of water to be employed. On the outside plates the grade of the plates will make a great difference in amount of water required.

THE "purple of Cassius" was discovered by Cassius of Leyden in 1683. It consists of gold and the oxide of tin, and is employed in coloring glass and glazes shades of violet, red and purple. It may be made by dissolving one-half gramme of gold in nitro-hydrochloric acid, composed of 16.8 grammes of hydrochloric and 10.2 grammes of nitric acid, and the solution diluted with 14 liters of water. To this solution is added, drop by drop, a solution of a mixture of protochloride and tetrachloride of tin.

THE consumption of cyanide on fresh concentrates varies with the composition of the concentrates. It is said that concentrates containing marcasite cause a greater loss than those of pyrite alone. The presence of copper compounds, physically soft, also tends to increase consumption of cyanide. The hard, dense sulphides of copper affect cyanide solutions but little, but those partly oxidized cause great loss. Some zinc sulphides containing gold can be treated with cyanide, but this can never be determined without experiment.

BY PRESSURE alone particles of pure gold may be made to cohere, but nuggets, found in placers, are not the result of pounding together of numerous small pieces and flakes of gold by the rocks associated with it in the stream. The effect of the detritus upon particles of gold in the bed of a stream is to reduce each particular piece, whatever its size, to a smaller size, and to eventually practically destroy it by abrasion. Though no longer visible the particles of gold—infinitesimally small—are still in the bed of the stream.

THE right to follow a vein on its dip beyond the side line of a quartz claim, known as the "extralateral right," in no manner refers to placer claims, or to ancient river channels, no matter at what depth, or under what conditions they occur. If no known paying mineral had been discovered on B's claim up to the time of issue of patent, any discovery subsequently made would not effect his title. The fact that B had previously made a mineral location on the land would make no difference if he did not really find mineral in paying quantity.

GRAVEL DEPOSITS containing gold which are located below the level of an adjacent stream may be worked by means of the hydraulic elevator, by means of which the gravel is carried upward in an inclined box or pipe by a

stream of water directed upward under heavy pressure. The height to which the gravel may be hoisted in this manner is dependent upon the quantity of water and the head available for the purpose. This principle is now being employed to keep the water in the Comstock, Nevada, mines 400 feet below the Sutro tunnel level.

IN THE placer deposits of California occur gold, native copper, lead, platinum and nickel, also diamonds and iridosmine, but the most common is the black sand, partly magnetic, probably derived from the greenstones and other eruptive and intrusive rocks. In Calaveras county, one mine near Mokelumne Hill has become noted for the large and abundant quartz crystals found in the wash. These are probably derived from a vein occurring near the place where the crystals have been found, but the vein has not as yet been discovered. Petrified wood is abundant in many river channels, ancient and recent.

GOLD is the only metal which has a yellow color in mass. The introduction of impurities changes its color greatly. Silver lowers and copper heightens it. In a state of fine division, when prepared by volatilization or precipitation it assumes various colors, as violet, ruby, and reddish purple, sometimes nearly black. Some eminent chemists have thought these colors due to an oxide film, but the most careful tests have failed to show the presence of oxygen, and the highest authorities now claim it to be metallic gold. Gold in thinly-beaten sheets is transparent and by transmitted light is green, of lighter or darker shade, according to the thickness of the sheet.

THE order in which stamps fall is of importance. It has been found that they can not be permitted to fall in sequence, as 1, 2, 3, 4, 5, as this would have a tendency to drive all the pulp to one end of the battery. For similar reasons they should not fall in any manner calculated to cause pulp to accumulate in one portion of the mortar while it becomes low in another part. The drops most in use are 1, 3, 5, 2, 4 and 1, 4, 2, 5, 3; 1, 5, 2, 4, 3 and 1, 5, 3, 2, 4 are also in use. In most mills ten stamps on a single section of the cam shaft are arranged so that no two shall drop at the same time. This is accomplished by setting both batteries to drop in the same manner, the No. 1 of the second battery falling immediately after No. 1 of the first, the entire ten stamps falling in the same time that is required to drop the five in both batteries.

THE Sutro tunnel at Virginia City, Nev., was driven under a special permit by Congress. No other tunnel has since been able to condemn a right of way through property belonging to others, to reach property owned by the tunnel owners lying beyond. Therefore, those desiring to locate a tunnel site must be the first to locate in the vicinity. Following is the text of the United States Statutes concerning tunnel locations: "Where a tunnel is run for the development of a vein or lode, or for the discovery of mines, the owners of such tunnel shall have the right of possession of all veins or lodes within 3000 feet from the face (meaning mouth) of such tunnel, on the line thereof, not previously known to exist, discovered in such tunnel, to the same extent as if discovered on the surface, and locations on the line of such tunnel, or (of) veins or lodes not appearing on the surface, made by other parties after the commencement of the tunnel, and while the same is being prosecuted with due diligence, shall be invalid; but failure to prosecute the work on the tunnel for six months shall be considered an abandonment of the right to all undiscovered veins on the line of said tunnel."

PANS for amalgamation in mills are always provided with a false bottom in sections, that the wearing parts, called shoes, may be replaced by new ones when worn. The idea of the pan no doubt originated from the arrastra. Ores are worked in pans either raw or roasted. In addition to ore, water, salt and bluestone are added, and steam turned into the charge which is ground, the muller being lowered for this purpose. When the pulp has been ground to the proper fineness and the original chemical combinations of ore broken up, the muller is raised slightly and quicksilver added, and the pan is again revolved for several hours, usually from six to eight. If the mullers were not raised it would result in the sulphides and mercury being ground to such a fine state of division that the quick would become floured and rising to the surface float like soapbuds on the top of the charge, being eventually lost. When amalgamation is supposed to be completed, water is added to thin the pulp and the quicksilver settles to the bottom, being drawn off through a "well" which is situated outside the pan and connected with it by a syphon. Beside the flowing mercury there is frequently found a considerable amount of hard amalgam attached to the mullers and sides of the pan. Ore containing black oxide of manganese causes the mercury to sicken, and this is usually corrected by adding a quantity of quicklime to the charge. In addition to the chemicals above enumerated, nitre, cyanide of potassium and sodium amalgam are about the only other ones used in pan amalgamation. The Boss process is similar to that above described, excepting that the pulp passes from pan to pan, the pans being set on terraces, each a little lower than the next. The first three or four pans of the set are used as grinders and the remainder as amalgamators. In a pan mill there are also settlers and agitators, employed to effect as complete a separation as possible of amalgam.

The Geologic and Economic Aspect of Tonopah, Nevada.

Written for the MINING AND SCIENTIFIC PRESS.

Like a rare jewel in its rough matrix, Tonopah is encompassed by an unique environment. Lying in the heart of the desert, remote from the highways of commerce, its surroundings must needs seem forbidding. Inaccessible, as measured by modern standards, it surely appears to the distant observer engulfed in a mirage, phantasmal, intangible.

Situated at an altitude of 6000 feet upon both a topographical and geological summit, with an elaborate system of veins, it promises to become a large producer of bullion as well as to become the center of a diversified mining district. In respect alone to the latter it invites serious investigation. There have been a number of discoveries within a radius of from 5 to 15 miles. While those outside discoveries are necessarily new and largely undeveloped, they nevertheless are impressed with noteworthy earmarks. The miners and prospectors of the outlying districts, accustomed to measure all values by the bonanza standards prevailing in Tonopah, are slow to grasp the real merit of lower grade ores. They are, it would seem, equally backward in discounting the future to the extent of recognizing that, with known reserves, present conditions can be readily and happily changed so that their ores may be marketed, or reduced to bullion, within limits of cost obtaining elsewhere.

The topography of southern Nevada is largely made up of a series of north and south ranges, or true geological anticlines, separated by parallel desert valleys, or synclines, which are generally from 20 to 40 miles apart. These anticlinal ranges are continuous for great distances, although sometimes terminating, like a great half-dome, in an east and west valley, which often join the flanking valleys of the north and south range.

It thus happens that, contrary to the law which so generally prevails, the anticline is preserved as the present topographical summit. Synthetically, the syncline or trough remains to-day as the topographical valley. Those valleys, which now constitute the true desert areas of that region, are totally devoid of running water and are studded with salt and borax marshes. Their transverse profiles are sweeping, majestic lines, and their altitudes generally about 4500 feet.

It is on the summit of one of those ranges that Tonopah is situated. The reader will therefore appreciate the bearing which such structural geology and coincident topography has upon the meager water supplies derived from intercepting works near the summits of such ranges. Thus it happened that water originally sold for 5 cents per gallon, and it is now commanding a price of 3 cents per gallon. Such supplies are necessarily secured from the seepage of limited catchment basins. The average annual precipitation is only about 8 inches. Evaporation is excessive over all those barren wastes, and the high winds which prevail throughout the greater part of the year only augment the atmospheric absorption.

Some of the ranges to the north of Tonopah, however, attain altitudes as great as 11,000 feet, particularly Mt. Jefferson and Ark Dome. At that altitude precipitation averages 40 inches. Evaporation is correspondingly decreased. Although those mountains are 70 miles north of Tonopah, their water supplies, if properly conserved, have economic value.

It must not be inferred that the surface rocks of Tonopah, or of that part of Nevada, are the older sedimentaries which had been subjected to folding. Upon them are superimposed great masses of later rocks—all of volcanic origin. The feldspathic silicates dominate much of the area. Along the axes of the anticlines lines of structural weakness developed. Those lines at a later period became the vents for volcanic flows which in a molten or plastic state overflowed the hillsides in great creeping sheets, reaching to the valleys below, and building up on the mountains, transforming and disfiguring the gentle contours of the country into more rugged and precipitous lines.

When a partial equilibrium had been restored to the source of volcanic supply, a semi-quiet period intervened, so far, at least, as the discharge of the volcanic products were concerned. It was during this period, probably, that considerable faulting and fissuring took place—creating many of the fissures which were then and later to receive metallic filling. Coincident, also, with this quietest period, the fissures and vents became the fumaroles from which steam, charged with gaseous combinations of chlorine, fluorine and sulphur, came roaring to the surface. Under such solfataric action, many of the rocks were greatly altered, while vein matter was derived from a deep-seated source. Thus it was that the lode-porphry, locally termed rhyolite, became an alteration product. Still later, as the hydro-dynamic forces became more stable, emissions of carbonic acid and combinations of hydrogen and carbon succeeded.

During these periods the ores were in process of

formation. It is not contended that their origin may be ascribed wholly to sublimation, but, perhaps, to a combination of agencies, in which sublimation, infiltration, thermal action and thermal mediums were all more or less active.

It is suggested that this brief outline of ore derivation is not put forth as a finality at this early date, but rather that it may serve to bring the subject into discussion.

Still later, and succeeding ore deposition, volcanic overflows again took place, thus capping the veins. As new vents and volcanoes were opened, they probably faulted and threw the veins into their present alignment. There can be little doubt that some of the buttes adjacent to Tonopah are extinct volcanoes.

In a width of perhaps 1500 feet there are fifteen known veins, all rudely parallel, and ranging in width from 18 inches to 8 feet. They stand nearly vertical and carry considerable known quantities of ore ranging in values from \$60 to \$150. Some shoots are of a much higher grade, while there are, of course, large bodies of much lower grade. Indeed, there are regions where the lode-rock is impregnated with commercial values for short distances from the vein—in some places for as great a distance as 20 feet. Those regions add, of course, to the measurable reserves, and, together with the lower grade ores, will become definite assets when local treatment and power shall have been introduced into the camp.

The veins strike west and southwest, while the axis of the range runs north and south. The vein system lies wholly on the western slope and within 1 mile of the summit. New discoveries to the west are being made from time to time, which add materially to the longitudinal extent of the system. This gives rise to the logical deduction, considering the unusual width of the fissure zone, that their metallic contents, covering the area they are known to cover, may be expected to extend to considerable depths. It was on a consideration of this fact, viz.: the relative length and width known in the early days on the Comstock, that the downward extension of that lode was predicated with a certainty that later developments strikingly fulfilled.

The nearest railroad station to Tonopah is either Sodaville or Candelaria, both on the Carson & Colorado Railroad, a narrow-gauge spur of the Central Pacific. Both are 60 miles west of the camp. Another outlet is had 110 miles north via Austin, which is the southern terminus of the Nevada Central Railway. This road is another narrow-gauge feeder of the Central Pacific.

Extensions from both roads can be made at a very reasonable cost and without involving excessive gradients or adverse alignment. It is believed that the distance to the projected Salt Lake & Los Angeles Railway will not be greater than the distance to Austin.

Via present connections, San Francisco is the nearest center, and it now enjoys most of the Tonopah trade. With a connection south to the Los Angeles road (commonly known as the Clark road), Los Angeles or Salt Lake will become the logical trade center for Tonopah and her district.

While nature has been prodigal of her mineral wealth in the veins thus far exploited, she has underwritten an antithesis of this in her niggardly provision for fuel. Wood sells for \$15 per cord. It has to be hauled from 12 to 20 miles. Stulls, 6 to 8 inches diameter and 7 feet long, sell as high as \$1 each. Fortunately, however, the ground is almost all self-sustaining, and the veins and country being very dry, there is no swelling. All sawed material is shipped 200 miles by railroad, thence by wagon 60 miles, costing, laid down, \$50 to \$70 per M feet.

With the exception of about 75 H. P. generated by steam, the remainder of the power of the camp, aggregating about 1000 H. P., is produced by gasoline. Gasoline, it is understood, costs 40 cents per gallon. On an estimated consumption of one-tenth of a gallon per horse-power hour, each horse power will aggregate about \$300 per annum for fuel alone on a 24-hour basis. If cost of attendance, oil, waste, repairs, depreciation and interest charges be added, power is costing by reason of the small units in operation not far from \$500 per power per annum.

The power thus far consumed is used almost exclusively for hoisting. There are a few small compressors actuating as many "chippy" drills.

Miners' wages are \$4 per shift. Board and lodging costs from \$1.50 to \$2.50 per day. Wagon freight on ore to the railroad is \$10 per ton, while incoming freight runs from \$20 to \$28 per ton, according to class. The cost of all freight and treatment charges aggregates about \$40 per ton—shipments going largely to Salt Lake and Selby smelters.

That the mines have continued to ship thousands of tons of ore under such adverse conditions is perhaps the most potent and flattering comment on the exceptional value of Tonopah ores. That prospecting and development goes forward with increasing energy, bespeaks a future for the camp which will be infinitely more eloquent and convincing than the most optimistic monograph could now portray.

The elements of uniqueness which dominate Tonopah as a camp and as the center of a mining district are seldom paralleled. Mindful that the camp has ore reserves of unusual extent, considering its short life and the adverse conditions of mining; with a posi-

tion in the midst of a desert, 60 miles from rail; without water in sufficient quantity for either metallurgical or steaming purposes; without fuel and without power; without reduction works and without a nearby market for its ores, its unique isolation is accentuated. These desiderata emphasize the inviting field offered for the necessary adjuncts of power and water.

OBSERVER.

Tonopah, Dec. 26, 1902.

Experiences of a Working Miner.

Written for the MINING AND SCIENTIFIC PRESS.

The way some people sink shafts would astonish you. Naturally you would expect the superintendent of a mine to know how a shaft should be sunk, even if he were not himself capable of personally executing the work. Of course we all believe the superintendent should possess sufficient experience, or talent, or something, to see that his shaft is kept straight when there is no object in the world to make it otherwise. The B— mine was down 500 feet and the shaft was being sunk deeper. In connection with this it is merely incidental to say that no single 100-foot section of the shaft, between the 500-foot station and the surface, was really straight. In some manner—just how I am not aware, unless it was the fault of the timber framers—the north end of the wall plates on the 500 level were several inches lower than the south end. D— was a new foreman and ran things to suit himself. He saw a way to remedy the trouble. He would cut the posts short on the high side for several sets and level up the wall plates. This was in an inclined shaft, pitch about 53°. Some of the more experienced shaft men suggested that the difficulty could not be satisfactorily remedied in that manner, but D— persisted, and as a result when the 700 level was reached the shaft was not less than 13 feet out of line, having swung to the northward, and also taken a twist of not less than 10°.

**

The assay office is sometimes a good place to pick up a few points, as well as in the depths of the mine. R— was assayer and chemist for the W—M. Co. He had a great many assays to make, so he said, an average of possibly eight daily. He used to keep the buttons he made in the process of assaying, both concentrates and ores, and also chips cut from gold bars for the purpose of making bullion assays. He managed, by being very careful and saving all the buttons, and all that remained over from chips from bars, about \$250. This seems a ridiculously small reward for such industry and tbrift. Still there are many others in similar positions who do not do as well, being able to increase their earnings during a year perhaps to the extent of \$1.00.

**

T— was foreman of the K— mine at J—. He had been there a long time and had never met with a serious accident. He had begun to believe that he was proof against them until one day while riding down on the skip he suddenly felt himself suspended in the air while the skip rolled on away down into the depths of the mine. His candle had gone out, but he knew what had happened. Some projecting object on the hanging side had caught in his jumper and "bung him up." For only a few seconds did he hang when he could feel the garment beginning to give, tearing away under his weight; suddenly it gave way, and as he swung around he frantically clutched at the timbers and succeeded in throwing an arm over a center brace. As quickly as possible he reached the bell line, stopped the skip, and rung the signal to hoist slowly. When the skip seemed to be about 50 feet below, T— clutched the greased rope and slid down to the skip and then rang to hoist. He went to the surface, thankful to be alive. Two or three weeks later his dark hair had turned to white.

**

When J— first became superintendent of the N— mine at S— he was anxious to have the whole world know it and never failed to tell whomsoever he might meet of his appointment to the position. He proposed to revolutionize things, too, and put in power drills. He was sinking a dry shaft, and the first round of bores had been put in and fired. I chanced to be idling, when J— approached me. "Doing anything in particular?" he inquired. "No," I replied. "Well, come up to the mine with me. I want to see how that round of bores broke. You know we are using machine drills now, since I have become superintendent."

We went to the mine and went down on the skip. No one on shift, the men had fired and gone, before supper. We stepped off the skip and slid down the timbers to the bottom. About half a skip load of rock broken.

"Guess they didn't shoot after all," said J—.

"Yes they did," I replied. "This is all freshly broken rock." We looked around and only the collars of a few of the bores were blown off. I looked

more carefully to ascertain the cause and found each of the dozen or more holes to have been pointed straight in. No "cut" holes, no provision for relief. All in 5 to 6 feet and not a hole broken. They would have to be burned out or cut holes drilled.

"Did you expect them to break put in this way?" I asked. "Cert," said J—, "Why not?" I explained my idea to him and he evidently saw the force of my argument, for I heard of no further trouble in that shaft on that score.

**

D— was an inventor. He had a deep, far away look, always dreaming of something. He dreamed one of the most ingenious devices for mining that for utter worthlessness it would be hard to beat. B— was a mining man with money. He met D— and a combination was formed. D— told his dream to B— and the foundry at A— got the benefit of it. They spent months in the construction of this strange and wonderful creation of D—'s. It was built and changed, altered and changed again, until it was pronounced complete. It was furnished with a good boiler and engine, had teeth and claws, was adjustable in every way, and the only unsolved problem was how to remove the rock which was to be torn down by this digger. It was taken to a mine near S— A— and set up in an open cut where a face had been carefully prepared for the beginning of operations. The rock was rotten amphibolite schist, that could be picked down with a sharp stick. The engine and its digging claws were set at work, but for some unexplained reason it would not do what was expected of it. The lowest limit of capacity had been set at 30 feet per day, but this machine did less than that, for it did not even do 1 foot and it cost several thousand dollars to learn this.

A Suggested Mining Method.

The following unique method of stoping and filling is suggested by a Colorado correspondent:

The drawing represents a vertical section of a portion of a mine in which the block of ore A between the levels is being worked out.

B is a small hoist with two drums on which are wound the ropes suspending the cages C and D.

Sketch Showing Proposed Mining Method.

These ropes are supported on pulleys E along the roof of level, the last of which pulleys is carried on a traveling derrick F whose boom projects sufficiently beyond the edge of solid ore to enable the cages to swing clear.

The cage C carries a horizontal drill-bar with ordinary lengthening device to allow of its being rapidly fixed between foot and hanging wall. On this bar are supported one or two drills according to width and nature of vein.

The cage D is used by the blasters and timbermen, and can be raised, lowered, or swung outwards from the face independently of C.

As the cages have little to carry beyond the men and their tools, they may be made of light weight. In the case of C, the cage is rather an appendage of the drill-bar than vice versa.

It might be described as a traveling bin from whose chutes the mine cars are filled. This bin must be made of strong material and always kept partially full to withstand the shock of falling rock. If preferred it may be dispensed with altogether and the rock filled by hand or steam shovel.

In order to protect the cages when hoisting the upper portion of the face, they must be hoisted up

to their pulleys and run back along the level. For this purpose, in order to avoid the necessity for excessive height in the level, the bottoms of the cages must be capable of being raised. This may be accomplished in a variety of ways as, for instance, by having the lower portion of cage suspended by chains from the upper.

The conditions best adapted for the successful employment of this method of mining minerals are: 1. Such a width between walls that stulls only are required for support. 2. Such a pitch as will cause the broken rock to run to a lower level. 3. At least fairly strong walls. 4. A practically regular pitch between levels.

The Use of Oil for Fuel.

TO THE EDITOR:—I have read the excellent article on the use of oil as fuel by the manager of the Selby Works. Regarding the use of oil as fuel for roasting in such localities as this, it may be said:

1. Roasting ores at inland smelters, where the ores are only concentrated into copper matte, either for converting at the same works or to be shipped to the refineries near the coast markets, is unnecessary when hot blast is used.

2. The cost of oil for fuel, either for roasting or under the boilers, is much more expensive than coal, at the present price for oil delivered here, due to the high freight charges made by the railroads. Yet I can not let the oil subject drop without saying a few words in its praise as fuel.

About the year 1888 the Florence oil wells of Colorado had accumulated a lot of residuum, left over after the lighter oils had been distilled off, for which they could only find a limited market until the American Smelting Works of Leadville, Colo., (then in charge of the writer), and the Henrietta and Maid Erin mines, also of Leadville, started to use this residuum as fuel under their boilers. The results were so satisfactory that the American Smelting Co. continued using oil as fuel under their boilers until the fall of 1893, and also used oil as fuel for their roasters, where the results were extremely satisfactory, due to perfect combustion, which enabled the men in charge of the roasters to obtain much lower sulphur assays from their roasted product than when

using coal; but by the time we began to appreciate the value of oil as fuel for roasting, the price had advanced, due to the increased demand, and the railroad company made us the concessions asked for in freight charges on slack coal, so that we did not continue to burn oil except under the boilers and in the lead hulsion concentrator—our partial refining furnace. We used steam with the oil burner as an atomizer at the boilers and refinery, but ordinary cold blast with the oil burners at the roasters, instead of steam.

Where oil can be obtained at reasonable prices, it is certainly a much better fuel than coal, and the results obtained in roasting furnaces or cupelling furnaces more satisfactory. S. E. BRETHERTON.

Val Verde, Ariz., Dec. 31, 1902.

MINERS may organize local mining districts and may pass laws not in conflict with the laws of the United States. The size of quartz locations cannot be made to exceed 1500 feet in length by 600 feet in width, nor can they compel a locator to take less than 1500 feet in length on the lode, but the width may be reduced to any reasonable number of feet on either side of the lode.

Method of Mine Sampling.

TO THE EDITOR:—I have noticed several articles in your journal discussing, pro and con, the best methods of making mining reports, whether on the gross or net value of the ores in sight, with the engineer's guess as to its availability for dividends and future work. This is a matter that, undoubtedly, every man will have to decide for himself, according to his own ideas and according to the wants of the men for whom he is reporting; but, possibly, a few suggestions on this subject will not be taken amiss. At any rate, these suggestions will do no harm, even if they do nothing more than produce some thought.

As a general proposition, the intending purchaser for whom the engineer is making the report knows nothing of the property whatever. He is absolutely without any knowledge of the conditions surrounding the property, and the things that may appear clear to one on the ground have to be explained in detail to one who is not on the ground. The engineer's best friend in making a mining report is the camera. It explains so much better, and without words, that which is so hard to convey in black and white.

Generally speaking, the value of a mine depends upon three things:

First.—The value of the ore per ton.

Second.—The number of tons exposed in the mine, with a guess as to what may be found in the future.

Third.—The expense of extracting its values.

As a starting proposition, the ore in the mine should be divided into three heads:

First.—Positive ore: That which is exposed on four sides, as, for example, a block of ground between two levels, with upraises in the ore connecting two levels.

Second.—Probable ore: That which is exposed on two sides, as between two levels.

Third.—Possible ore: That which is exposed only on one side.

The usual custom in determining these values is to take samples of not less than 100 pounds across the thickness of the streak, stating at the same time the thickness of the sample taken in feet and inches. This will give you the value, and, by determining the cubical contents of the block of ground, the number of tons may be approximately determined.

Then the following questions should be answered as nearly as possible. Of course, the questions to be elaborated will be determined according to the conditions of the mine:

1. Where is the mine located?
2. How many claims are upon the vein, and how many are located for purposes of protection?
3. How long is the vein, so far as known, on the strike, and who owns it at either end of the property?
4. What development is shown on neighboring property on the same vein that will give an index to the value of the property upon which the report is to be made?
5. What power for milling and mining purposes is available? If water power, give the distance from the mill or mine and describe it.
6. Answer the same question with regard to fuel, with cost at mine, whether wood, oil or coal.
7. What transportation facilities are there? This includes the kind of road, the state of the road or the same in regard to trails, with distance to markets or railroads.
8. What is the scale of wages paid for the different occupations?
9. Is the labor good, bad or indifferent?
10. Give an idea of the character of the country, whether rolling or precipitous, whether the mine would be worked by shaft, tunnel on the vein and crosscut, or if a milling proposition, state what disposition could be satisfactorily made of the tailings. This will include the question as to whether there are rivers near by and anything about the country that might be interesting.
11. Where is the nearest postoffice?
12. How thick is the vein from wall to wall?
13. Describe the character of both walls, the class of rock, with the character of the vein filling or gangue.
14. State whether the rock is hard or soft and the probable cost of development per foot, and if wall rock has to be broken or crosscuts made. State this separately.
15. How thick is the pay streak or streaks, with their distance from each other, if more than one?
16. What will the pay streak average as broken down? This means without sorting.
17. If it requires sorting, what percentage will be thrown out as waste?
18. What will the whole streak run in the different metals, giving each percentage by itself?
19. So far as known, will the pay streak be continuous, meaning by that, one in which all the development would be done upon ore?
20. Is the streak lumpy, or does the ore come in shoots, with waste rock in between? Give full description on this point.
21. What work has been done on the vein with stopes, and the production of each, so far as possible?
22. State the class of reduction to which the ore

is susceptible. If ore is extracted at mine, state percentage of recovery and cost per ton. If of a smelting nature, give the rate of treatment accorded by the smelter, and railroad and wagon freight.

23. Is the vein wet or dry?

24. If wet, state the amount of water in gallons per minute, and state if the water is at all acid in nature.

25. Is the mine being worked at present? If not, why is the property idle?

26. In sending maps, send both maps on plan and vertical elevation, showing the contour of the outcrop.

27. In giving assays, give all assays taken, whether good or poor, even those on waste rock.

28. Are the titles clear or clouded?

29. Does the ore change in character or value as depth is gained from the surface?

30. Give the past production of the mine in dollars and cents, as well as the percentages of the different metals and price received at time of sale.

Silverton, Colo., Dec. 27, 1902. S. I. HALLETT.

An Experience in Drift Mining in Hard Cement Gravel.

NUMBER II—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by L. H. CARVER.

EQUIPMENT AND METHOD OF SAVING GOLD.—The next important feature, after determining the presence of gold in paying quantities, and opening up sufficient ground to develop, as far as possible, the extent of the pay, is to determine the best method of saving it.

We will not attempt to describe the various ways by which this is accomplished, under the different conditions where drift mining is carried on, but will confine this article to a description of this particular plant, which has successfully handled the material and produced satisfactory results.

At present the gravel is hoisted in an iron bucket, but it is our intention to put in a skip, which will obviate the necessity of a man to land it, and require occasional attendance only.

From the time the gravel is loaded into the bucket from the bin, in the sump at the main shaft, and hoisted, it is carried by gravity to the mill and requires no further handling, the material being dumped on the grizzly, drops into a large bin directly underneath, from which a short chute, controlled by a gate, allows it to pass to a Challenge automatic feeder and then into the mill, from which the pulp, after flowing over the table, is carried into the tailings flume and discharged into the gulch.

A 5-stamp mill is used to crush the cement, which is quite hard and compact, the stamps weighing 900 pounds and dropping 5 inches about ninety times a minute, which seems to give the most satisfactory results; the discharge is kept at about 4 inches, by chuck blocks of varying heights, and the screen used is the ordinary steel wire cloth, with five holes to the inch. A larger quantity of water is turned into the mortar than is customary in quartz milling, and carries the pulp onto the table as soon as reduced to the required fineness.

The battery water is taken from the tail-race, after passing the water wheels, and was frequently found to carry oil on the surface (drippings from the various machinery under which it passes); to prevent this oil from reaching the mortar the battery water box or launder from the tail-race was dropped 2 inches below the main flume, and a strip of wood inserted, acting as a weir in the tail-race, and raising the surface of the tail water sufficiently above the aperture to the battery water flume, which is also controlled by a gate, to carry off all impurities and prevent their being drawn into the mortar.

The sectional drawing, Fig. 3, shows the manner in which this was effected.

After passing the screen the pulp flows over a wooden table, the full width of the mortar and 10 feet long, set to a grade of $1\frac{1}{2}$ inch per foot.

This table is built with 2-inch smoothly dressed sugar pine planks on the bottom, the width of the planks being such that only one joint was necessary, the sides being 6 inches wide or high.

I am reminded here of a method to secure an absolutely water-tight joint, where the contact edges are of considerable length, that was suggested to me by the head carpenter at a large hydraulic mine in southwestern Oregon, where I was engaged in designing and installing the plant, several years ago, and has since been used by me with very satisfactory results. It was a new one to me and may be of interest to others.

Dress the edges of the planks which are to form the joint to an even contact; set one of the planks on edge, and with a short piece of round iron—the end of which is bent up about 90° to enable one to hold it in position— $\frac{1}{4}$ to $\frac{3}{8}$ inch in diameter, make a continuous groove along the center of the edge of the plank, by sinking the rod into the wood by striking with a hammer; then dress the edges down again evenly to the bottom of the groove thus made, and fit the joint together and securely fasten in place.

The compressed fibres along the groove, upon wet-

ting, will swell out against the edges of the adjacent plank, making a joint that will not only be water-tight, but will successfully resist a very considerable steam pressure, if used in that connection; it being

FIG. 3.

understood that such a joint is to be used only where the planks can be securely tied together with iron rods.

Continuing with the original subject, across the bottom planks of the table and at right angles to the flow, were cut four channels, $1\frac{1}{4}$ inch deep and $2\frac{1}{4}$ inches wide on top, and shaped accurately—as shown in the cut—to a template; the distance between channels being gradually diminished, approaching the lower end. (See Fig 4.)

FIG. 4.

In operation, the action of the pulp and the results were admirable, a continuous roll taking place at each channel, where the pulp was turned over and over before escaping.

Quicksilver was fed into the mortar at regular intervals, and the last channel on the table was kept fully charged also; the three upper channels, however, received no "quick" except that accumulating from the pulp, and the uppermost one required cleaning up every day, a string of amalgam as large as one's thumb remaining here after the day's run.

The other channels were left with their accumulations of amalgam until the run was completed.

From the table the pulp dropped into a launder across the end, and from which it passed through an amalgam trap, constructed with three partitions in a square box, being similar to a short section of a cyanide precipitation box, and thence into the tailings flume, which was provided with nests of riffles at intervals in its length, and served to arrest any quicksilver that escaped from the trap.

No copper plates were used, the greater part of the gold being quite coarse and heavy, and the fine gold escaping the upper channels being caught in the last channel, the results showing a very close saving as compared with the sample values, taken at regular intervals at the feeder, it being estimated that a little over 90% of the gold contents of the gravel was gathered from the mortar and the table, of which the mortar furnished approximately 23%; first channel, 32%; second, 18%; third, 10%; fourth, 15%; and the amalgam trap and riffles, 2%.

The wide difference in the saving between the mortar and table is due to the low discharge, large screen mesh, and the quantity of water admitted to the mortar.

There is considerable "rusty" or "red" gold, which is also saved on the table, and gathered up separately, as it refuses to amalgamate until rubbed in a pan, to remove the coating of iron oxide.

The general character of the gold is the smooth washed, clean, channel variety, varying in size from "flour" to pieces weighing 50 cents, all of which yields readily to amalgamation, and a few nuggets have been found valued as high as \$3.25.

Under the conditions as stated, the mill is capable of handling from forty to forty-five tons per day, and the cost of mining and milling was found to be between \$1.30 and \$1.40 per ton, with material that will average, in actual work, about \$2.25 per ton,

but considering the fact that the gravel extracted so far has been taken from an overflow it augurs well for the values to be obtained in working the channel proper and the future productiveness of the property.

The entire plant, it may be said, is operated by water power, 2600 feet of 11-inch pipe, under a head of 185 feet, about 40 miner's inches being required for the hoist, mill and two pumps.

Some further changes and improvements are contemplated, however, that will effect a greater economy in handling the material, and, it is also hoped, a greater saving of values.

A Study of Amalgamation Methods, With the Object of Avoiding the Loss of Mercury.*

NUMBER IV.—CONCLUDED.

By MICHAEL BUSTAMANTE, JR., M. E., City of Mexico.

The two principal signs observed in the usual tests which have hitherto served, and will doubtless continue to serve as a practical guide in the operation of the patio process, confirms part of the theory here presented.

1. The test of a "cold" torta, made immediately after the incorporation by trampling, shows mercury, sometimes in part more or less confluent, but usually in small drops, or the exceedingly fine state of division (floured) which we call *liz*. Rubbing this together and then attempting to strain it by squeezing we obtain scarcely any signs of amalgam. The mercury is very white, resembling its natural color, or tending more or less to a yellowish color on the surface, owing (as experts say) to the formation of sub-oxide of copper. The film of this oxide, covering the surface of the mercury, is undoubtedly due to the decomposition of the chloride of copper by the oxides of iron in the ores; and the quantity of chlorine thus liberated from the copper salt is not sufficient to form the needed amount of perchloride of iron, which, acting in the nascent state and favored by the heat liberated in its own formation, is the true agent in the chloridization of the silver compounds. Hence the "coldness" of the torta, with the unfavorable conditions which that implies. This phenomenon led me to suspect for the first time the important part played in the patio process by the iron oxides and salts of the ore.

2. On the other hand the torta is "hot" when an excess of sulphate of copper has been added. In this case, perchloride of iron is very rapidly formed and tends to be reduced with similar rapidity to the proto-chloride, converting the mercury to calomel (Hg_2Cl_2), until the reaction provoked by the immoderate use of sulphate of copper has terminated. In this case, practically all the reagents employed are consumed in the chlorination of the mercury without useful result. The greater part, if not the whole, of the iron oxides in the ores is changed to proto-chloride; and if, after the overheated torta has cooled, pure sulphate of copper be employed to continue the treatment, much difficulty will be experienced in recovering the conditions lost.

Inventors, reasoning upon the reaction of the Freiberg harrel amalgamation, have proposed the use of metallic iron in the various phases of the patio process, as a means of minimizing the loss of mercury. The main result of such a measure has been the requirement of a larger quantity of sulphate of copper, together with delay in the progress of the treatment. The reason is easily seen—the metallic iron precipitates metallic copper and this reaction cools the torta. The consumption of mercury increases instead of diminishing.

In view of these facts and considerations it is, in my judgment, the best practice to conduct the treatment of the torta moderately and with vigilance and upon the least sign of excessive heat to apply the remedy at once in the form of a quantity (calculated as exactly as possible) of lime, precipitated copper, or ashes, to forestall the effects of a "hot" torta upon the mercury, as is the case when the torta is hot.

As already observed, the proper amount of sulphate of copper required in this process for any particular ore should be as carefully determined, according to the law of chemical equivalents, as the amount and nature of flux required in a smelting process. And it follows that for this process, as for smelting, different ores might be so mixed, after proper analysis of each, as to diminish the necessary amount, or increase the effectiveness of the metallurgical reagents added. Empirical mixtures of "docile" and "rebellious" ores are known to have given excellent results in many Mexican localities; and there is a wide and promising field for the thorough study and systematic application of this practice, which would raise it from the plane of local tradition or happy accident to that of definite purpose and foreknowledge.

In this, as in other respects, the Mexican amalgamation process has never had opportunity to exhibit its full technical and economical capacity. I firmly believe that it can successfully compete with smelting, especially in a country like ours, in which, by

*Transactions Am. Inst. Min. Eng.

reason of topographical conditions and the cost of fuel, freight will always be high.

With regard to methods for diminishing the loss of mercury and amalgam, I would here recall the experiments in connection with the amalgamation of gold, described in the first part of this paper. I have similarly employed the electric current in connection with the patio process also—not to affect the treatment itself, but to join the metallic particles. The result was, as I had expected, the same as that which had been accomplished with gold. The quantity of silver and mercury recovered was considerably increased; and I succeeded in saving 97% of the humid-assay value of silver with a loss of only 5.1% of the mercury employed.

The apparatus consisted of a series of amalgamated copper plates connected to the poles of the dynamo and grouped in tension, so as to obtain, per square meter of surface, from one to two volts and forty amperes of current. These plates were so suspended by means of the canals and inside of the drain of the patio in such a manner as to interrupt, to a certain extent, the free passage of the slimes and water, but without seriously hindering or complicating the washing of the torta. I am fully conscious that, after more than seven years spent in establishing facts, overcoming difficulties and perfecting details, my work in the economic utilization of the facts and theories set forth above is, like my attempt to state them here, still far from complete and satisfactory. Nevertheless, this paper, begun two years ago, is now published, in the hope that the suggestions and experiments of others may aid in the improvements and the due recognition of our Mexican patio process, so little understood, so often undervalued and so worthy of a better fame and fate.

The New Home of the Paraffine Paint Co.

The Paraffine Paint Co. will move into their new building at No. 24 Second St., San Francisco, Cal., about Feb. 1, 1903.

So popular have become the P. & B. products and the demand for them has grown so rapidly within the past years that the company has recently added to its factory equipment in Paraffin, Alameda county, Cal., and now intend to increase their office and salesroom, to meet the demands of this increased

New Home of Paraffine Paint Co., San Francisco, Cal.

business, by occupying the three lower floors in the handsome new structure built for them.

This building is centrally located, being within a few steps of Market street and just within a half block of the Palace and Grand hotels. The floors are 26 feet wide by 90 feet in length and are connected by freight and passenger elevators.

The street floor will be used as main offices and sample room, while on the other floors a good-sized stock of ready roofing, building papers, paints, etc., will be carried for the San Francisco trade. Out-of-town orders are shipped direct from the factory.

The Paraffine Paint Co. have been located at No. 116 Battery St., San Francisco, Cal., for the past sixteen years.

The Mining Industry of the Cœur d'Alenes, Idaho.*

NUMBER II.

By J. R. FINLAY, Colorado Springs, Colo.

METHODS OF OPERATION.—The mining industry of the Cœur d'Alenes may be divided into three departments: 1. The extraction of the ore from the ground, or actual mining. 2. The concentration or milling, which, at every property in the district, with two exceptions, includes transportation of several miles from mine to mill. 3. The shipment and sale of the concentrated ore.

In general terms, there is a loss in concentration of from 20% to 30% of the gross values, and the

nearly of the same depth, 2000 feet or more.

These three mines are equipped with Corliss hoisting engines of the same make and size, which were made by Fraser & Chalmers, with 20x60-inch steam cylinders, flat ropes and reels, designed to hoist as much as 2500 feet. They can be run with or without counterbalance.

No mechanical devices of special interest are peculiar to the district, with the exception of an electric light hoist signal system, recently installed at the Standard mine. It is possible that this device may in time become more widely known and extensively used. It consists of a signal box in the hoisting room and at each station in the shaft. Electric lights are placed in these boxes behind ground glasses, on which are marked the desired signals. Switchboards placed near the boxes enable the station tenders to turn on the signal lights, which burn until they are turned off by the engineer with a throw-out

Timbering and Filling Stope, Bunker Hill & Sullivan Mine.

freight and treatment charges amount to 40% of the gross selling price of the concentrates, leaving the mine owner from 42% to 48% of the gross value in the ore to cover the cost of mining and milling.

For example, I have said above that the ores mined in the district would average by assay about 10% in lead and seven ounces silver per ton. The lead and silver are sold to the smelters say at "brokers' quotations," the smelter paying for 90% of the lead and 95% of the silver in the ore. At present prices the gross value of the above mentioned ore would be:

90% of 200 lbs. = 180 lbs. lead, at 3.5 cents.....	\$6.30
95% of 7 ozs. = 6.65 ozs. silver, at 55 cents.....	3.66
Total.....	\$9.96

Of this total gross value, after deducting concentration losses and freight and treatment charges, the mine owners' residuum of 42% to 48% amounts to from \$4.20 to \$4.80 per ton. The cost of mining and milling will be, under varying circumstances, \$2.50 to \$3.50 per ton, and the net profit remaining will be, therefore, from \$0.70 to \$2.30 per ton.

MINING.—At least 70% of all the ore thus far mined in the Cœur d'Alene has been extracted through tunnels, without hoisting or pumping. Of the remaining 30% which has been hoisted, at least two-fifths has been hoisted through underground shafts, to be subsequently hauled out through tunnels. The Tiger-Poorman is the only mine which has always been operated by shafts from the surface. This large proportion of tunnel work has been a great advantage to the district.

There are many long and well-constructed tunnels, designed to serve for the final exploitation of the mines. The principal ones are: The Sweeney (Wardner, about 5000 feet long); the Reed (Wardner, about 5500 feet); the Kellogg (Wardner, about 12,000 feet); the Frisco (Gem, about 1200 feet); the Standard (Mace, about 3000 feet); the Mammoth No. 6 (Black Bear, about 3600 feet); the Hecla No. 3 (Burke, about 2400 feet); the Morning No. 5 (Mullan, about 3000 feet); the Morning No. 6 (Mullan, now being driven, 10,000 feet).

Each of the mines operating the above tunnels has a number of other adits, some of them of great length; but these are of earlier and less elaborate construction, and serve for the working of upper levels.

The principal shafts of the district are the following: The Tiger-Poorman (sunk from surface 1700 feet); the Hecla (300 feet); the Standard (in Campbell tunnel, 3000 feet from the surface and 850 feet deep); the Frisco (in Frisco tunnel, 1200 feet from surface and 1400 feet deep).

Measured vertically below the outcrops, the Tiger-Poorman, the Standard and the Frisco mines are

device. The chairs for landing the cages in the shaft are provided with an attachment which, when the chairs are thrown out to receive the cage, automatically turns on, in plain view of the engineer, a warning light, marked with the number of the level at which the chairs are out. The signal lights burn both in the stations from which the signals are given

Timbering and Filling at the Standard Mine.

and in the engine room. This enables the station tender instantly to see and correct any false signal. It is practically impossible for the engineer to receive a false signal, and, as he knows the exact position of any chairs which may be out in the shaft, there is no excuse for smashing cages.

Three methods of mining are used in the district: 1. Back stoping and timbering. 2. Back stoping,

*Trans. Am. Inst. Min. Eng.

timbering and filling. 3. Back stoping and filling without timbering.

At the Bunker Hill & Sullivan the most interesting feature of the underground mining is the extraction of wide bodies of low-grade ore by stopes which are filled, as the work progresses, with waste rock sorted from the broken ore. There is usually more than enough of such material to keep the stopes full, and provision has to be made for tramping the surplus waste away. Sometimes this hack stoping is done without any timbering other than an occasional prop to support a suspicious looking piece of ground in the roof; but more commonly the stopes are timbered with light square sets. (Fig. 7.)

In stoping the ore at the Standard (see Fig. 8) it has been found necessary to fill up the stopes with barren material from the vein. This is done by the simple process of sorting out part of the waste rock from the barren streaks and from the walls, and throwing it down among the timbers below. It is easy, in most parts of the mine, to secure in this way enough filling to keep the stopes full within two or three floors of the hack. As the levels are 200 feet apart, it is necessary to build massive cribbed chutes up through the timbers.

The timbers are of two kinds, square sets and stull sets. The square sets are 9x5x6 feet, and are built in the usual way. The stull sets are merely caps, cut, if possible, long enough to reach from wall to wall, set horizontally and supported by two posts. If the vein is over 15 feet wide the cap is made in two sections, joined together on a third post. Three-inch plank is used for flooring or lagging.

The timbering has always been massive and elaborate. Only the abundant supply of cheap timber, which is one of the advantages of the region, renders such heavy timbering economical.

Every facility is provided for the easy handling of the timbers inside and outside of the mine. Each level is equipped with two good hoists, operated by compressed air, to hoist the pieces into the stopes. To provide for these hoists and for the ropes and sheaves, the first floor above the track floor is left open and free from filling.

(TO BE CONTINUED.)

Wallace Steel Crusher.

The Wallace sectional steel crusher illustrated herewith is stated to have a daily capacity of from twelve to thirty-six tons. The parts subject to the hardest wear are made of steel to resist a strain of 120,000 pounds. As there is no strain on the framework, it is made of iron or wood as desired.

The vertical lever or crusher bar is built up with 1x7-inch steel bars. The bars are separated by hard-wood timbers of sufficient thickness to bring the lever to required width, bolted so as to bring the strain edgewise on the steel bars. The crusher bar

Wallace Steel Crusher.

has both a vertical and lateral motion. The movable jaw or crushing plate is attached to the lever. The jaw is held in place by means of a clamp at top of jaw. The jaws can be taken up 1 inch by an adjustment and designed to still retain the same degree of fineness in the work. The crusher is provided with a safety or breaking pin. Should a foreign substance get into the crusher, this pin will shear off and allow the movable jaw to drop back and permit the obstacle to pass through without injury to the machine. The bolt can be easily replaced. The mill is designed for crushing and pulverizing of rock, clay, cement, graphite, or anything else desired to crush. It can be adjusted from $\frac{1}{8}$ to $\frac{3}{4}$ of an inch. It is designed to be well adapted to a jig proposition, with intent to prepare the material for the jig without any further crushing machinery, and is intended to work equally as well on wet or dry material. Each mill is provided with one loose pulley and two fly wheels, one of which serves as a driving pulley. This crusher is manufactured and for sale by Chas. Wallace, 1420 Market street, Denver, Colo.

The Hendrie & Bolthoff Establishment.

The Hendrie & Bolthoff Manufacturing & Supply Co., for the past thirty years manufacturers and dealers in mining machinery and supplies, Denver, Colo., has recently moved into their new building 17th and Wyncoop streets, opposite the Union depot, Denver, Colo. The building has been remodeled to

light and handsome exhibition room. The gallery extending around this floor is also used for exhibiting machinery.

On the second floor is the private office of the president of the company, Mr. E. B. Hendrie. On this floor also is a commodious drafting room and large fire-proof vault for filing drawings. About one-half of the second floor is occupied by fine tools and machin-

The New Building of the Hendrie & Bolthoff Mfg. & Supply Co., Denver, Colo.

meet their requirements. It is built of red pressed brick and is 125 by 150 feet, four stories and basement, giving them approximately 100,000 square feet of floor space. The cellar extends under the entire building and is used for the storage of heavy pipe fittings, of which they carry about 100 carloads in stock. To handle goods economically they have put in a hydraulic elevator in the basement to the ground floor and an electric elevator from basement to fourth floor, in addition to which they employ an electric passenger elevator.

The rear of ground floor is devoted to the shipping

ists' supplies, which are all kept in cabinets built for this purpose. The remainder of this floor is taken up with brass goods, valves and mining screens.

The third floor contains helting, hose, packing and rubber goods, etc. A large space is allotted to shovels, several carloads being carried in stock. On this floor the firm has fitted up a large room with tables and chairs for the use of its employees as a lunch room.

On the fourth floor they carry a large stock of Dodge wood pulleys, arranged on racks, jack screws, pumps, gasoline engines and other material. They

An Interior View of the Hendrie & Bolthoff Mfg & Supply Co.'s Establishment, Denver, Colo.

department, a portion of the space being arranged to permit of the wagons driving into the building and loading under cover direct from the shipping platform. The orders are assembled on benches and each order checked by two men to avoid errors before being loaded for shipment. The shipping facilities are excellent, having as they do railroad tracks on both the east and west sides of their building. This gives them special advantage in the economical handling of both incoming and outgoing shipments.

The offices are handsomely fitted up and occupy about one-third of the ground floor space. The remainder of the space on this floor is entirely devoted to displaying purposes and at the present time shows one of the largest displays of mining and milling machinery ever placed on exhibition in a sales room. An open court extending to the second floor makes a

have an electrical repair shop where the firm makes its own switch boards and does its own electrical repairing. They intend also putting in a large stock of electrical supplies.

They have four large warehouses, having a combined floor space of 150,000 square feet, situated on the railroad tracks, in which are stored the heavier machinery and supplies, sheet steel, pipe, rail, boilers, engines, concentrators, compressors, hoists and electrical machinery.

The firm report greatly increased business since occupying their new quarters. The officers of the company are: E. B. Hendrie, president; H. Bolthoff, vice-president; C. F. Hendrie, treasurer; H. P. Waterman, secretary. The accompanying engravings give a good idea of the appearance of the establishment.

Fifth Annual Report Lincoln Mine.

The fifth annual report of E. C. Voorheis, superintendent of the Lincoln Gold Mining Co., Sutter Creek, Amador county, Cal., dated Jan. 5, 1903, is at hand, and is in part as follows:

On May 24th we completed sinking the main shaft to a depth of 2000 feet. Fifteen feet above the bottom of the shaft we drove a crosscut into the footwall 81 feet, 10x12 feet in size, to increase the capacity of the sump. At a point 1950 feet from the surface we cut a station and chute, which we call the 1950 level. The chute will hold 100 tons. This work was completed by June 30th.

DETAILED STATEMENT OF COST OF SHAFT SINKING.—Following is a detailed statement of cost and time required to sink the Lincoln shaft 740 feet, from 1260 feet to 2000 feet. The size of the excavation is 8x17 feet. Material encountered in sinking, greenstone and hard black slate.

The labor cost of sinking and putting in timbers was as follows: It required 3864 holes drilled in the bottom of the shaft, or 5 2 per foot of shaft, which took—

2956 days' labor at \$2.75 per day.....	\$7,129 00
One day foreman, 350 days at \$4 per day.....	1,400 00
One night foreman, 282 days at \$3.25 per day.....	916 50

Total cost of sinking 740 feet and putting in timbers..... \$9,445 50

Labor cost per foot for sinking 740-foot shaft..... \$12 76

12,450 pounds Hercules powder were used, costing..... 1,307 25

Cost of powder per foot of shaft..... 1 76

Amount of powder used per foot of shaft, 16.8 pounds..... 125 30

35,800 feet of fuse were used, costing..... 17

Cost of fuse per foot of shaft..... 17

Amount of fuse used per foot of shaft, 48.4 feet..... 46 00

Forty-six boxes of Lion caps were used, costing..... 06

Cost of caps per foot of shaft..... 06

2400 pounds of candles were used, costing..... 288 00

Cost of candles per foot of shaft..... 39

Three and two-tenths pounds of candles were used per foot of shaft.....

148 sets of timbers were put in place, requiring 207,200 feet of lumber at an average cost of \$18 per M..... 3,729 60

Cost of lumber per foot of shaft..... 5 04

Amount of lumber used per foot of shaft, 230 feet.....

Total cost of labor, lumber, light, blasting material..... \$14,941 65

Cost per foot for labor, lumber, light, etc..... \$20 19

Total cost of labor for engineers, blacksmiths, framing timbers, and skip tenders..... 6,224 00

Cost of top expense per foot of shaft..... 8 41

Total cost for fuel for sinking 740 feet..... 5,893 50

Cost of fuel per foot in sinking 740 feet..... 7 96

Total cost of sinking shaft, including all expense except office expense..... \$27,059 15

Total cost per foot of shaft..... \$36 56

During the time the shaft was being sunk 60,025 tons of water were hoisted.

9456 tons of waste were hoisted from the bottom of the shaft to the surface, making a total of 69,481 tons hoisted.

COST OF RUNNING LEVELS AND CROSSCUTS.—The following is a detailed statement of the cost of running 1175 feet of drifts and crosscuts on the 1950 level. Most of the rock was hard greenstone:

1428 days labor (miners at \$2 75 per day and car men at \$2 50 per day) amounting to..... \$3,772 50

168 days for day foreman at \$4 per day..... 672 00

134 days for night foreman at \$3.25 per day..... 435 50

Total labor cost for drifting and crosscutting 1175 feet..... \$4,880 00

Average labor cost per foot..... \$4.153

11,150 pounds of powder were used, costing..... 1,226 50

Average cost of powder per foot..... 1.043

26,500 feet of fuse were used, costing..... 79 50

Average cost of fuse per foot..... .068

Thirty-five boxes of Lion caps were used, costing..... 35 00

Average cost of caps per foot..... .03

800 pounds of candles were used, costing..... 96 00

Average cost per foot for candles..... .082

Total cost per foot..... \$5.376

Total cost..... \$6,317 00

3258 blasting holes were drilled.

Average number of holes drilled per foot, 2 77.

The average amount of powder used for each blasting hole was 3 42 pounds.

Average amount of fuse per foot, 22 feet.

Average number of caps per foot, 3.

Average amount of candles per foot, 68 100 pound.

Average size of tunnels, 5x8 feet.

Following is a detailed statement of the work done at

the mine from January 1st to December 31st, 1902:

16,103,400 gallons of water were hoisted from the mine during the year; 10,487 tons of waste were hoisted; 77,592 total tonnage hoisted from the mine during the year; 4547 blasting holes drilled; 16,250 pounds of dynamite used; fifty-six boxes of Lion caps used; 41,100 feet of fuse were used; sixty-three 40-pound boxes of candles used; 4047 barrels of oil were burned for fuel during the year; the compressor ran 2782 hours; the engineer made 41,797 trips with water, waste, timbers, etc. All buildings, machinery and tools are in good condition. Rainfall from January 1 to December 31, 1902, 24 68 inches.

Total disbursements since organization of the company, \$197,951.06.

E. C. VOORHEIS, Superintendent.
Sutter Creek, January 5, 1903.

New Coal Dust Burning System.

Written for the MINING AND SCIENTIFIC PRESS by C. O. BARTLETT.

We have perfected and put into practical operation a system for burning soft coal which we believe is worth the careful consideration of all users of soft coal. By this system we get a perfect combustion—in other words, no black smoke; a saving of 25% in the amount of coal used; no cinders at all and scarcely any ashes. It requires no change in the grates used under any ordinary boiler to install this system, and in case of accident coal can be fed at the

Rowe Feeder System.

furnace doors the same as before. The supply of feed can be changed at a minute's notice by simply turning a hand wheel. The doors are not opened at all, thus doing away with all undue contraction and expansion caused by the admission of cold air through the furnace doors as in the old way of firing. No fireman is required.

The writer maintains that to get perfect combustion three things are necessary: The coal must be of uniform size; it is impossible to get the same results from burning a chunk of coal as big as a man's head and another piece as big as a pea. The coal must be made of even size before perfect combustion can be had.

The coal must be of equal moisture; the same result cannot be obtained from burning coals of different moisture. Run of mine coal containing 5% to 6% moisture will not give the same combustion as slack coal containing 10% to 12% moisture. The idea of wetting coal before putting it in the furnace or admitting steam jets under a boiler is nonsense.

Powdered coal must be burnt in suspension. If it is swept or pushed into the furnace the heavy particles will fall to the bottom and become a solid clinker, which is objectionable and almost impossible to get out, but by burning in suspension absolute combustion is obtained.

With these three important features in view we have perfected and are now using under our boiler at Cleveland, Ohio, a system by which we first dry the coal, using the cheapest kind of slack coal and drying it down to 2% moisture, then grinding it down to eighty-mesh fine, which makes it practically coal dust. We then use what is known as the Rowe feeder system, which is described as follows, accompanied by drawing shown: The ground coal is stored in an iron storage hopper or tank above or near the boiler. An air pipe, "A," is connected with feeder spout at the furnace and above the boiler in the breeching or stack, a blower fan is attached to this pipe of sufficient size to furnish the necessary air for burning the coal dust. The operation is as follows:

The coal is conveyed by a special conveyor from the bottom of the storage bin to a spout, "B." The speed of this conveyor controls the amount of coal used and can be changed at a moment's notice by turning a hand wheel, that is, to feed faster or slower according to the amount of fuel desired. From the conveyor the coal is fed direct to the air spout, "A." There is a nozzle, "C," on the inside of the air spout which concentrates the air just as it strikes the coal as it comes down from the conveyor, which gives a thorough mixture of the coal with the

air and at the same time prevents any danger of clogging. The coal is caught by the current of air and blown along the air spout to the furnace spout. Just before entering this spout there is another nozzle, "E," which again concentrates and mixes the air with the dust just before it enters the feed spout, "D." This feed spout is made of cast iron and has a semi-circle opening or mouth so as to spray the coal dust up and against the arch wall, where it is ignited and burned in suspension. This spout is covered with firebrick for protection, and the current of air continually passing through it also protects it from burning out. In fact, there is nothing about this system which is not very durable, and this we consider a very important feature in any system. There are slides or valves on the different places in the air pipe so as to admit just enough air to get perfect combustion, all of which are under the complete control of the operator.

A Shift in the Mill.

Written for the MINING AND SCIENTIFIC PRESS.

"How're they stacking up, old man?" I remarked to my partner coming off shift. "Rotten, Jim, rotten! I've had a lively old night of it—broke a shoe in number eight, two feeders on the bum, tappets slipped in three and ten, and two or three screens

broke. The ore has been low and the feeder man had to be in the ore bin half the time picking down; then lazy Jack down there on the concentrators went to sleep after eating his lunch and let his sulphuret boxes run over. You'll find the plates in pretty good shape; but I guess you'll have to feed a little more, silver, as they're sending us some rock from the 1650. Well, so long, Jim; hope things don't buck as hard with you." "So long, Bill; this is good weather for you night men to sleep."

After changing my clothes an examination of the plates shows they are getting thick. As Bill had remarked they are sending us some of that buncy rock from the 1650. The helper having things ready we start to dress the plates. Looking down on the lower floor, the vanner man seems to be cussing about something. Oh, yes, one of those old worn out belts has broken and he's trying to patch it up. Super says the stockholders are howling for dividends, and it's pretty hard to get new things in a hurry. Well, by the time we have gone over the plates of the whole sixty, and the amalgam cleaned and squeezed out, it is nearly 9 o'clock.

Going down to the safe to lock up the amalgam, I hear a lively hammering, and look around to find that the feeder tappet on number six has slipped. Catching sight of Henry sweeping up, I hold up six fingers. He runs upstairs, hangs her up, and sets the tappet.

"Henry," I said, after making a round to feed "silver," "just keep an eye on the batteries while I take Jim's report over to the office, and stop at the blacksmith shop to have this tappet key drift fixed up." Returning, who should be looking for me but my old partner, Jack Winkle. You know, about five years ago, Jack and I run the little 10-stamp mill, opposite shifts, at the Howling Coyote, down near the desert, and this is the first time I've seen him since. Well, sir, he is now on his way to British Columbia to take charge of a 40-stamp mill. Making a round of the batteries, and finding things going along all right, Jack and I sit down on some timbers outside the door and have a chat over old times. He has been working at Jackass gulch, about 10 miles back of us here, for the past six months, and neither of us knew the other was so near. As the whistle blows for noon he starts down the road toward the hunk house to catch the stage. Well, I guess I'd better eat my lunch.

My ears tell me that some of the stamps are not hitting right, and glancing out I see the feeder man hiking down the line with a piece of bread and meat in hand and his jaws working vigorously. He stops at number nine and changes the feed, and soon the stamps resume their steady roar. Lunch being over, the first thing in order is to set the tappets on four and seven—the drop is getting too long.

First thing I know here comes the feeder man with a worried look on his face: "Say, Jim, come take a look at number eleven; one of the stamps is wobbling all over—first it drops about 2 inches and then about 10," he shouts in my ear. "A broken shoe, my boy," I yell at him as I reach for the cam stick. "D—those foundry people, any way; why can't they send us decent castings? That last lot of shoes are the hummest I ever saw." Going down stairs: "Hey, Henry! open up number eleven and drive off that broken shoe." Well, that job done, and operations resumed, let's sit down and have a quiet smoke

for a few minutes. Wonder what will happen next?

Long about 4 o'clock here comes the super. "Jim, you boys will have to keep your eyes peeled a little closer down here; the tailings are running high the last few days." "All right, Mr. Spry, we'll make a change or two. You know we have been getting some of that buncy rock from the 1650—an occasional carload." I thought there would be something doing—life would be too easy if there wasn't a kick coming from somewhere once in a while.

A half hour later: "A-ha, that feeder man again," at sight of dark streaks on number two's plates, indicating grease. "Look a-here, Joe, haven't I told you to be more careful when you are oiling those stems? I'll not tell you many more times."

Well, I guess as soon as I've weighed up the "silver" and made out the day's report, it will be about time to wash up and change my clothes.

"Hello, Bill—yes, it has been a little strenuous to-day. Not much time to sit down and think about it. Sleep well, to-day?" "Best I've done for a month." "Say, Bill, the super says tailings are going too high. I had Jack raise his vanners a bit. Well, good night, Bill." "Good night, Jim."

BOSS HEAD.

Mining and Metallurgical Patents.

Patents Issued December 30, 1902.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

AMALGAMATING APPARATUS.—No. 717,195; J. J. Hill, Denver, Colo.

In amalgamating apparatus, combination with supporting frame, of basin for holding body of quicksilver, copper cylinder having ribs at intervals on surface and supported in frame to rotate in basin with its surface always above surface line of body of quicksilver below it, and pulp passage formed between basin and cylinder and constricted toward its overflow side.

CONVEYER.—No. 717,063; C. J. Allen, San Francisco, Cal.

Conveying apparatus consisting in combination of single, rigid inclined track, having return bend and lower terminal adjacent to higher end of track, burden carrier, hoisting rope secured to higher end of track, fall rope secured to lower end of track, guide sheaves in line with track and above respective ends thereof through which ropes pass, connections between ropes whereby they are raised and lowered in unison, and stop means at lower end of track operated by movement of ropes by which carrier is prevented from leaving track while hoist is being operated.

DRILLING DEVICE.—No. 717,095; L. A. Hardison, Santa Paula, Cal.

In well drilling machine, combination with tool operating shaft, same having usual operating means; duplex rope engaging drum revolvably mounted upon shaft, and provided at one end with internal and external bevel gears, and band engaging channel on outer circumference; sleeve longitudinally movable on shaft and provided at one end with external beveled gear, adapted to engage, at extreme of longitudinal movement, with internal gear on drum, and having at other end worm gear; bull wheel revolvably mounted on sleeve, sleeve having longitudinal movement therein, bull wheel having internal beveled gear, adapted, at one end of stroke, to engage external beveled gear on drum, and means to throw gear in and out.

SLUICE OR RUNWAY.—No. 717,301; G. Telford, Oroville, Cal., assignor to Risdon Iron & Locomotive Works, San Francisco, Cal.

Sluice or runway provided with deflecting plates 5 pivotally secured at upper ends to sides of sluice or runway and being suspended longitudinally thereof, free end of each deflecting plate being provided on under surface with series of transverse strips 6 rigidly secured thereto, strips being inclined or beveled in the direction of flow through sluice or runway.

VALVE FOR AIR COMPRESSORS.—No. 717,029; E. Reynolds, Milwaukee, Wis.

In combination with cylinder-head having opening extending therethrough; valve seat mounted in and resting against shoulder formed in forward end of opening; valve guide also mounted in opening having central stem G formed with pockets I, J; head H formed upon end of stem; enlarged portion O connected to stem by ribs Q, and ports P; cup shaped valve mounted upon head H; shell N intermediate

valve seat and enlarged portion O; and springs K and L mounted in pockets I and J respectively.

ROCK DRILL.—No. 717,027; J. H. Redfield, Spokane, Wash.

The combination with drill shaft having fixed collar, of cam shaft recessed intermediate of its length to permit passage of collar, and cam mounted on shaft having operating face extending approximately from axis of rotation of shaft; pair of actuating cams mounted on shaft at each side of recess, cams each having curved operating face and straight radial face, curved face extending approximately from center of rotation of shaft, and radial face being in alignment with recess of cam shaft.

BOSH PLATE FOR BLAST FURNACES.—No. 717,248; J. C. McCausland, Pittsburg, Pa.

Bosh plate provided with continuous horizontal chamber which extends from front to rear and from side to side thereof, horizontal division plate extending through chamber from rear nearly to front and dividing chamber into upper and lower compartments which communicate only at inner end of bosh plate, and water connections located at outer edge of bosh plate and on opposite sides of line of union between division plate and outer end wall of bosh plate.

ATTACHMENT FOR ROCK DRILLS.—No. 717,028; J. H. Redfield, Spokane, Wash.

An attachment for rock drills, comprising auxiliary crank shaft, bracket carrying same, tube to which bracket is secured, socket member carried by tube and adapted for application to and pivotal movement on main crank shaft of drill, and gearing connecting the shafts.

Specimens Received.

C. B. Ferguson of Copper Mountain, Alaska, sends to the office of the MINING AND SCIENTIFIC PRESS handsome specimens of crystallized epidote, associated with fine quartz crystals and iron ore; also, several specimens of beautifully crystallized grossularite—a variety of lime alumina garnet. These minerals are of common occurrence in the gangue of copper ores, but not often found in such handsome specimens.

The rock specimen received from Michigan Bluff, Placer county, Cal., is green chert, or jasper (quartz), and has no commercial value. The color is probably due to iron. It is probably a greatly altered sandstone.

Mining Summary.

Specially compiled and reported for the
MINING AND SCIENTIFIC PRESS.

ALABAMA.

CALHOUN COUNTY.

It is reported at Anniston that for two years a 20-stamp mill has been in operation near there on ore averaging \$36 a ton. The mine is 20 miles from Anniston and 70 miles from Birmingham. The ledge runs 1½ mile northeast and southwest. The paystreak varies in width from 2 feet to 4 feet.

ALASKA.

A. Wacberg, who has quartz and placer claims on Kodiak island, says he has been prospecting on the island for ten years and speaks well of the quartz mining outlook, but denies the report that there are good placers. He has several placer claims, but says they are of little value. Wacberg, with the Uyak G. M. Co., has built a 10-stamp mill, which will be in operation March 1, and expects to have other mills in operation.

A miners' meeting was held at Valdez January 2nd to consider the adoption of miners' rules for the Valdez recording district. The principal topic discussed was that of restricting the location of claims by power of attorney.

A report from Douglas says the Seven Hundred mill at Treadwell is to be moved across the channel to Silver Bow basin back of Juneau. The company expects to have the mill in operation there by June. A 10-stamp mill has been ordered for the Nevada creek properties and will be in operation by March 1. The company will employ 200 men next season. M. Hudson of Douglas is superintendent of the work at Nevada creek.

ARIZONA.

COCONINO COUNTY.

J. J. Penhale, manager the Hance Asbestos M. Co., whose properties are in the Grand canyon north of Williams, says he has twenty men at work and is packing the product of the mines to the rim of the canyon, using thirty burros. He shipped their first car of asbestos to the Eastern market this week.

COCHISE COUNTY.

The Copper Glance M. Co., near Bisbee, employs thirty-two men and will establish eight hours for all kinds of work, says the Review.

The Dos Cabezas G. M. Co. has now developed water and their machinery is being put in place.

At the Lowell mine, near Bisbee, they are driving a tunnel from the railroad to the shaft, where they will put in a landing station. At the Calumet and Arizona property the tramway is in operation.

GILA COUNTY.

J. P. Faull and P. Oates have given an option on their coal claims, the Reed group, in the San Carlos district, northeast of Globe, to the Saddle Mountain M. Co., who want coke with which to smelt their ores. Manager Chittenden of the Saddle Mountain Co. says he will begin operations next week.

MARICOPA COUNTY.

Work is resumed in the White mine near Wickenburg.

Griffin and Breed have bonded the Vermonter group to the Arizona Leader Mineral Syndicate of Cleveland, Ohio. This group consists of four claims in the Hassayampa district, south of Prescott, near the Senator mine.

The Monte Verde M. Co. will be organized to develop these claims. W. G. Reese, of Prescott, is manager.

MOHAVE COUNTY.

Work on the German-American mines, near Kingman, is going ahead. On the Treadwell the shaft is down 200 feet and in ore. At the Pioneer the shaft is down 100 feet and the company is putting up a hoisting plant. Electric drills will be used. At the 35th Parallel a tunnel is being driven on the ledge.

A gasoline hoist is being set up at the Queen Bee mine, near Chloride. The collar of the main shaft has been retimbered. H. Lefler is foreman and J. Deter, superintendent. The Elkhart mill is in operation. J. Barry is putting up a hoist on the Town mine. Superintendent L. Hoffman is shipping ore from the Samoa mine by pack train.

PINAL COUNTY.

W. A. Langhorn and partners several months ago bonded a number of claims on Picocho peak to California men. They have run a tunnel 186 feet and 100 feet of

drifts and crosscuts and have cut the main lead.

The Bonanza G. M. & S. Co., near Casa Grande, will put in steam hoisting works, air compressor and drills. J. C. Loss is manager.

YAVAPAI COUNTY.

At the Morning Star mine, near McCabe, Superintendent M. J. Enright is making a paying mine out of a promising prospect.

It is reported a good body of ore has been opened in the Gold Dust mine of the Hudson group, near Prescott. The ore is grey copper and runs \$50 per ton in gold.

The Poorman mine at Walker is being developed under bond by J. W. Francis of Flagstaff. The shaft has been enlarged and is being sunk. A vein 4 feet wide carries values in gold and silver. The owner of this property, A. H. Mitchell, is superintendent.

The Treadwell smelter at Mayer is in operation with oil burners, the change from coal burners being completed.

A hoist and other machinery are being installed at the Lelan mine at Chaparral. The main shaft is down 200 feet, with 600 feet of drift and tunnel. E. Wells is superintendent.

J. Caspar has bonded his group of claims, near McCabe, to Douglas, Lacey & Co., who have put on three shifts sinking. Caspar remains in charge of development. A hoist is being put in at the Cypress mine. The Parker mine, southwest of McCabe, is putting up a hoist.

It is reported that the mine fire in the United Verde copper mine at Jerome, that has burned for the past four months, has been extinguished by employing carbon dioxide in large quantity and excluding oxygen.

CALIFORNIA.

AMADOR COUNTY.

The Bay State mine, north of Plymouth, has begun sinking the shaft 300 feet deeper, which is down 800 feet. Rock is being milled from two ledges. Twenty-four men are employed by the company. W. W. Worthing is superintendent.

The Southerland Bros., sinking a shaft on their claim on the ochre lead west of Plymouth, are down 45 feet.

A body of ore was cut last week in the south drift on the 1000-foot level of the Fremont Con. near Drytown. C. E. Purington, superintendent.

CALAVERAS COUNTY.

The company owning the Occident-Keystone mine at Mokelumne Hill have begun the construction of a cable suspension bridge. They will put in cars, tracks and machinery for an 80-ton per day plant.

Work is reported suspended at the Last Chance mine, near Angels.

A shaft is being put down on the Independence gravel mine on the Birney ranch, 1 mile from Angels. It is intended to go to bedrock. Several attempts have been made to reach bedrock in this ancient channel, but thus far have failed, owing to large volume of water found.

The Chronicle says at the Keystone-Occident mine, near Mokelumne Hill, a winze is being sunk in the tunnel, and at a depth of 10 feet 4½ feet of ribbon quartz has been cut, carrying free gold and galena, assaying \$15 per ton. On the Belvoir mine, an extension of the Keystone-Occident, the ore has developed a pay shoot. These properties belong to the Black Cat Oil & M. Co.

The Beatrice mine at Murphys has its machinery in and mining is resumed.

DEL NORTE COUNTY.

The North Del Norte mining district, south of Waldo, Or., is attracting attention. Since the copper discoveries made last spring miners have gone into the district and many claims taken up are being developed. H. W. Jackson and C. W. Baker of Del Norte have 1100 feet of tunneling done on ore that carries silver and gold.

P. Clark of Spokane has a bond on the Albright mine, in the district. He has men at work.

EL DORADO COUNTY.

The Glebenhain Bros.' stamp mill last week finished a run on ore from their mine at Poverty Point, near Placerville. —C. Edner is said to have made a strike in his gravel mine at Omo.

During the year 1902, 333 location notices and 249 certificates of labor were filed for record with the county clerk upon claims in El Dorado county.

In the Volcanoville district, at the Two Channel mine men are sluicing and preparing for the winter's run. Water is running in the Daggett ditch and men are at work on Buckeye hill. The Josephine tunnel No. 5 is being driven.

At the Montezuma mine at Nashville the north shaft is down 400 feet and the 10-stamp mill is in operation.

KERN COUNTY.

The December cleanup of the Butte mine, near Randsburg, from eighty-nine tons at the Red Dog mill resulted in three bars worth \$6000.

LOS ANGELES COUNTY.

Crude oil is advancing in price. It is now worth 74 cents a barrel in the local market. Fourteen gravity oil which sold for 40 to 50 cents a barrel the last twelve months now commands 74 cents.

The Home Oil Co. has its third string of tools at work at Whitlier, drilling well No. 18, south of No. 15.

G. Robinson has the contract for drilling a well for the Central Oil Co. at Whitlier.

NEVADA COUNTY.

The Telegraph says an estimate on the amount of ore produced during the last twelve months is placed at \$1,200,000. The amount of ore crushed was 83,000 tons. In developing properties 27,500 feet of work has been done at a cost of \$225,000. The amount of money paid for wages was approximately \$520,000.

The Ironclad M. & M. Co. property, at Rough and Ready, is sold to the Gear-Ironclad G. M. & M. Co. H. M. Black, E. F. Irwin, S. J. McConnell, A. Wright, G. C. Hay is superintendent.

PLACER COUNTY.

At the California M. Co. at Shady Run fifteen men are working and gravel is being taken out. R. A. Watson, superintendent of the Shady Run M. Co., says the lower tunnel will be extended 3000 feet to tap three pay shoots. The upper tunnel is in 400 feet. It is expected that the first shoot will be reached in 500 feet. The ledge is 22 feet in width. The property has a 5-stamp mill.

At the Rawhide Con. M. Co. twenty men are at work. The main tunnel is in 720 feet. Ore from the mine is conveyed from the ledge to the mill at the river, a distance of 2100 feet, by an aerial ropeway with buckets.

G. Nissen, owner of the Annie Laurie mine, near Colfax, is building a ditch to carry water to his claim.

The Alameda G. M. Co. at their mill in Black canyon, near Westville, have ten stamps dropping and they have battery space for ten more when required.

Superintendent C. D. Akers of the Hidden Treasure mine, above Forest Hill, says the company is taking out an average of 2500 cars of gravel per week.

The new mill at the Bonnie Bee mine, near Emigrant Gap, is in operation. The main tunnel is in 500 feet. Twenty-eight hundred tons of quartz have been taken out. The Zebright mine, 200 yards east of the Bonnie Bee mill, and an extension, is to have a 20-stamp mill in the spring, says the Sentinel.

At the Great Channel mine, southwest of the Hidden Treasure, near Sunny South, the tunnel is in 1920 feet and an upraise started to strike the gravel.

ORANGE COUNTY.

Well 34 on the Santa Fe lease, in the Fullerton field, is down 2600 feet. The company is said to be looking for light oil in this well.

PLUMAS COUNTY.

A. W. Whitney has reopened the New York mine in Indian valley, near Greenville, and has started up the mill, ten men being at work underground. —At the Johnny Bull mine, recently bonded to C. Droege and M. Connell, Eastern parties, a cyanide plant is being installed.

SANTA CLARA COUNTY.

After twenty years' idleness the original shaft of the Guadalupe quicksilver mine is again open and work is in progress. Since August 12, 1902, pumps have been working to unwater the mine. The 200-foot level is opened and it is reported that the ore is rich.

SHASTA COUNTY.

The Mountain Copper Co. is unloading twenty-five carloads of coke at the smelters at Keswick. This is what remains unsold of recent large importations.

C. F. Nourse has sold to the Iron Mountain Inv. Co. the Alice Fraction quartz mine in Flat Creek district.

The heavy rains of the past few days have swollen the little streams in small gulches, and placer miners are doing well. Near the old town of Shasta, L. Seiler, a school boy, found a nugget that he sold for \$49.21. At Newtown, in Buckeye district, I. Quinn found a \$35 nugget.

The Mountain Copper Co. is refusing entrance to mail and passenger stages to its property at Iron Mountain. The company also refused to accept rent money from occupants of its cottages near the mine, and has ordered all of its houses occupied by employees' families to be vacated. It is reported that should the strikers declare the strike off and desire

to return to work unconditionally the company would not allow them to do so. The company are credited with the assertion that they will not take back into its employ a single miner or smelter man who walked out when the strike was declared.

All the lands belonging to the Keswick Crude Oil Co. were jumped New Year's morning. Sixteen hundred acres were relocated by a party of twenty men. The land is in Sand Flat region, 3 miles east of Keswick. The claims jumped include the hole drilled by the Keswick Co. to a depth of 1000 feet. No work was done in 1902, as the company was involved in litigation and had no money in the treasury.

The strikers of the Iron Mountain Co. no longer ask for the reinstatement of the five men who were discharged for cause. All that is asked now is the recognition of the union. Work has resumed in a small way at the mine, where non-union men are caring for leaching vats and working at timbering and mining in the mine itself. No union men are allowed on the mine reserve, where a dozen patrolmen do guard duty.

SIERRA COUNTY.

Oklahoma capitalists will develop gold mines near Poker Flat. They are known as the Rose and Harold properties. A company has been incorporated for this purpose at Guthrie, Ok.

SISKIYOU COUNTY.

Whitney & Co. have pumped out their claim on the Klamath river, near Oak Bar, and are taking out pay gravel.

TUOLUMNE COUNTY.

The Altadena M. & I. Syndicate has sold to W. L. Holmes of Detroit ninety acres near Columbia, also the Kearsarge No. 2 and Altadena quartz mines.

Superintendent Bryant of the Prudhomme mine, near Carters, says he made on Jan. 1 a \$900 cleanup for nine days, the mill running one shift daily.

The compressor at the Big Casino mine, near Groveland, is in operation. —At the Two Brothers sinking is resumed and will go down 130 feet farther, at which point drifts will be run. —It is reported that a 6-foot vein of ore has been cut in the tunnel at the Shoenberg mine. —At the Mount Jefferson mine the mill is running on ore from the drifts east and west on the 400 level. A gasoline engine and pump are being set up to raise water from the creek for battery use.

The Banner reports during the year 1902 there were 448 locations of quartz claims recorded in Tuolumne county. There were seventy-one placer and gravel locations, fifty-six water rights taken up, seventeen millsites located and seven reservoir sites claimed and recorded.

COLORADO.

The Denver Post says the following figures represent the official reports from authoritative sources of the gold, silver, lead and zinc output of Colorado for the calendar year 1902. The only account omitted is that of the Colorado & Ohio smelter, located near Salida, which opened for business about December 1 and details of its production for the limited period are lacking:

Gold.....	\$27,416,941.94
Silver.....	8,146,092.21
Lead.....	5,221,109.20
Copper.....	1,088,763.34
Zinc.....	1,901,448.00
Total.....	\$43,774,354.69

According to the official report of H. A. Lee, State commissioner of mines, the output of 1901 was:

Gold.....	\$27,679,445.04
Silver.....	10,901,365.89
Lead.....	6,419,131.61
Copper.....	1,303,297.17
Zinc.....	1,095,224.00
Total.....	\$47,398,463.71

This shows an apparent loss of gold, silver, lead and copper, due largely to the demoralized condition of the metal market during the year, but a gain in zinc output. Another cause is the lower average grade of ores treated. While the tonnage output has been larger, particularly in Cripple Creek district, owing to improved processes, much lower grades have been handled. During 1902 the zinc ore sold and exported amounted to 60,000 tons, which averaged 32% metallic zinc. At an average price of 4½ cents, the total value was \$1,728,000. The Canyon City Zinc Works produced 3,854,400 pounds, all of which went into the manufacture of paint. At an average value of 4½ cents, the value was \$173,448. During 1903, by reason of the erection of two other reduction plants at Pueblo and Canyon City for the treatment of zinc ores, the yield will be increased.

BOULDER COUNTY.

Manager R. S. Earhart, the Colorado Northern G. M. Co., near Wallstreet, says they have completed the installation of their electric plant and have two box electric drills in operation. Regular shipments have begun from the body of ore opened in the winze sunk in the 1330-foot drift.

Sinking has been discontinued in the shaft on the Gold Lode, near Wallstreet, and drifting east and west from the shaft is under way.

Another strike is reported in the Long-fellow mine at Jamestown. The ore shoot on the second level, from which this company has been shipping for several months, has been opened at the third level 425 feet west of No. 2 working shaft. The new body is 3 feet wide, 12 inches of which runs \$250 a ton. Selected ore runs eight ounces gold and 1400 ounces silver per ton.

Last week two more strikes were made in the Boulder oil belt. The 2:10 - Mars joint well has 1000 feet of oil in the hole and will begin pumping this week. The Boulder-Valmont has struck the sand and oil is filling the hole. The sand has not yet been drilled through. Oil was reached at 1935 feet. The output for the belt was 13,304 barrels during the year.

M. S. Rafeld, treasurer of the Valley Forge G. M. Co. of Boulder, says operations will be resumed. The Valley Forge tunnel will be driven to the Fortune dyke which crosses the property.

The Tripp R. Co. has bought the Blast mine and mill at Ward. They will overhaul the mill and install a plant for the use of the Tripp process, of which roasting is a feature.

CHAFFEE COUNTY.

The W. B. Martin Leasing Co. has been incorporated at Colorado Springs to operate on the Raven claim of the Prudential M. Co. at Granite. The lease runs for three years and work was started this week. There are two shafts on the property of the Prudential, but the leasing company will sink another. In a 40-foot shaft on the property there is a streak of ore running \$35 per ton. This shaft is narrower than required by law, however, and it will be necessary to either enlarge and refit it or else sink a new one on the same vein.

CLEAR CREEK COUNTY.

The Clear Creek M. & R. Co., F. R. Carpenter general manager, whose smelter is at Golden, gives the following record for 1902:

	Value.
Gold—22,128.55 ounces.....	\$457,397
Silver—124,133 ounces.....	62,000
Copper—232,764 pounds.....	27,931

Total\$547,328

This was extracted from ores having an average value of \$10 per ton and largely from a single furnace. A second furnace has been added which will probably double this output in 1903. All of its product was sold in the form of copper matte and is included in the returns.

The Terrible mine at Georgetown is installing a 150 H. P. engine and boiler to be used as an auxiliary to meet emergencies.

Texas men have control of the Little Flat mines on Ute creek, near Idaho Springs, and are putting in a hoist and boiler and will sink the shaft to 1000 feet. W. A. Gable is manager.

The Waldorf properties near Georgetown, including the Paymaster, Commonwealth and Independence, are shipping out ore by pack train.

The Yankee Con. Co. will build a 100-ton amalgamating and concentrating mill at Yankee. A water power plant and dynamo will be installed to drive the mill and furnish power to the mines. A wire tramway 1½ miles long will be built between the Lombard and Faust mines to the mill.

The Manhattan tunnel will be continued and bids are being called for, for 200 feet. The sinking of the Faust shaft will begin and twenty-five men will be employed in this.

A contract has been awarded Craze & Freeman to drive the Central tunnel near Idaho Springs. The face is in 1542 feet.

Manager Teagarden, the St. Paul G. M. Co., has begun operations on the extension of the Aliunde vein. The company has five claims on the Aliunde vein. The tunnel will cut the lode 2000 feet in and give 1000 feet in depth.

CUSTER COUNTY.

It requires five four-horse teams to remove the concentrates from the Bassick mine near Silver Cliff to the depot for shipment, though the mill is working but one shift a day.

Work has been resumed at the Bull-Domingo, near Querida, one shift in the 550 and the other in the 1000 level. Fif-

teen tons a day are being hoisted. It will be treated at the Le Rand mill.

The Hillside R. Co. will put up a plant at Custer to treat the ores of the Rita Alta C. Co., of which H. L. Comstock is superintendent.

EL PASO COUNTY.

The United States Reduction Co. at their plants at Colorado City and Florence report for 1902 as follows:

	Tons.	Ounces Contained.
Standard plant.....	150,442	188,053
Colorado City plant.....	100,000	130,000
Union plant.....	125,000	156,250

The United States R. & R. Co., operating zinc works at Canon City, reports for 1902: Four thousand tons of zinc-lead pigment containing 60% zinc oxide and 40% sublimed lead white, having a valuation at the works of \$225,000; 400,000 pounds copper, 1200 ounces gold, 100,000 ounces silver.

The United States R. & R. Co. at Colorado City have bought the patent of D. Hawkins and H. W. Fox for manufacture of chlorine gas by application of electricity. The company will erect a plant for the manufacture of chlorine gas which will cost \$100,000.

FREMONT COUNTY.

The Stadacona Oil Co., a Canadian corporation, has leased oil land south of Florence, and has let the contract to A. Gullinger.

The Hector mine, near the Bassick, near Florence, is sold to the Melrose G. M. Co. and the name changed to Contact No. 2. Manager C. W. Haskell says the company proposes to erect a mill. Heavier machinery will be put in to further develop the property.

The Royal George Coal Co. has leased the Price coal mine near Canyon City and is installing machinery to reopen the property. E. G. Bettis is manager.

The Copper King concentrator and mill-site at Dawson camp, near Canyon City, have been sold by the sheriff to satisfy claims of men who built it, amounting to \$2500. The cost of the concentrator was \$17,000. J. S. Harris of Canyon City was the buyer.

The inflow of water in the Valley View M. Co. property near Florence is ninety gallons a minute. This is handled by the pumping plant recently installed. Three shifts are at work on the shaft.

Electric drills will be used in exploration work by the Peerless Copper Co., near Florence.

GILPIN COUNTY.

A company of New York men has been formed to operate the Freedom mine on Bates hill, near Central City. Two 80 H. P. boilers and an engine will be put in at the mine. The company is also negotiating for the Ridgewood mine. The pumping will be done from the Ridgewood, as there has been connection made between them.

The Gowers Mine Syndicate of London has taken a lease and option on the Pierce mine, above Central. Machinery is being placed. E. M. Messiter will have charge of the properties.

The shipments of ore from the Gilpin county mines to the smelters for December were 340 cars, or 6800 tons. For the entire year the shipments amounted to 4469 cars, or 89,380 tons. To this must be added 15,000 tons of concentrating ore shipped to the mills at Idaho Springs, which brings the total to 104,000 tons. The shipments to the local mills were a little higher than in the previous years, owing to the fact that a good deal of mill ore was formerly sent to the Golden smelter. Comparing these figures with those of 1901, the production of the county is over \$4,000,000. The shipments from Black Hawk for 1901 amounted to 70,946 tons, showing that for 1902 there has been an increase of almost 25%.

GUNNISON COUNTY.

It is reported that the Raymond, near Ohio City, will resume.

HINSDALE COUNTY.

L. Sherbino has let a contract for 300 feet of work on the Pennsylvania group in the Burrows Park district, near Lake City. Five men are at work on the property. The Dupre Co. has let a contract for 100 feet of work on the Cashier lode, Park district. Work began last week.

LAKE COUNTY.

The Fryer Hill Mines Co. at Leadville have completed dead work in the El Paso and are now breaking ore. Some of the ore in the old stopes carries fifty ounces in silver and a little gold. From the Jamie Lee, Cora Belle and Bangkok, shipments are going out regularly at the rate of 500 tons per day.

The Long Tom, on Sugar Loaf mountain near Leadville, is being prospected by a party of miners. They have cut the

lead at 125 feet in the shaft and are drifting on the vein. Taylor and Greene are in ore in their lease off the 600-foot level of the Little Ellen incline, Leadville. Fifteen tons daily are shipped of gold-lead ores.

The Bohn, at Leadville, is being operated under lease by E. L. Daniels. They are shipping iron ore and prospecting.

At the Rex combination, near Leadville, operated by the Keystone M. Co., the shaft is unwatered and sinking resumed. The shaft will be sunk another 100 feet and at that point it is expected to cut the mineral found by the diamond drill.

The Lillian mine on Printer Boy hill is producing 100 tons a month of gold ore through the different set of lessees. In addition to this, bodies of low-grade milling ore have been opened up which will be cyanided.

Superintendent Linderman says in the spring a mill will be put up at the Little Louise property, near Birdseye, Leadville district.

The Herald-Democrat's figures on production of the Leadville district show a total valuation for the past twenty-five years of \$298,000,000. The product for 1902 is \$9,468,544, divided as follows: Gold, \$1,302,680; silver, \$3,051,195; lead, \$1,694,410; copper, \$308,409; spelter, \$3,103,448; manganese, \$8400. The total tonnage for the year is given at 748,746.

P. K. Connolly has resumed operations at the Dolly B. in Evans gulch, Leadville.

The Valentine M. Co. near Leadville have completed the unwatering of their properties.

The Peerless and Peerless Maud, operated by H. Dyatt in the Horseshoe district, are shipping ore. Two pockets of lead carbonates have been opened and the ore will average \$25 per ton. Dyatt is building a concentration mill in connection with the Last Chance mine and will concentrate most of the product of these two mines.

MINERAL COUNTY.

Output from Creede Camp for 1902:

	Cars.	Tons.
January.....	291	4,803
February.....	256	4,563
March.....	281	4,710
April.....	275	4,778
May.....	267	4,593
June.....	384	6,475
July.....	361	6,596
August.....	377	7,003
September.....	347	7,079
October.....	366	7,719
November.....	337	7,362
December.....	176	4,210

Total	3,728	69,891
Silver, ounces.....	1,400,000	
Gold, ounces.....	17,560	
Lead, tons.....	31,000	
Zinc, tons.....	3,100	

This shows a decrease from 1901 of 851 cars, or 9600 tons; but the concentrates shipped in 1902 amounted to 3 to 1 in proportion to 1901. The price of silver operated against an increase in its production. The shipment for December is short, owing to a two weeks' suspension of shipments by the railroad changing from narrow to broad gauge. The shipments tabulated were made from the Bachelor, Commodore, New York-Chance, Del Monte and United Mines, on Bachelor mountain; the Ethel, Solomon, Ridge, Champion and Punxsutawney, on Campbell mountain; the Molly S, on Mammoth, the Corsair and Alpha, on McKenzie Mt., at Sunnyside. The principal development work of the district was the extension of the Humphrey tunnel 1000 feet and 3000 feet of drifting on the United Mines property.

The Manhattan M. & D. Co. has incorporated to operate at Creede. They own four claims joining the Alpha on the south. The vein has been prospected by shafts, varying from 20 to 30 feet, to ascertain its strike and dip, but the principal one is an incline 60 feet in depth, from the bottom of which a crosscut was run 70 feet, cutting the vein.

J. M. Jennings and R. H. Jackson have a contract to drive 100 feet in the Iowa tunnel, near Amethyst.

OTERO COUNTY.

The La Junta Oil & Gas Co. has struck oil in its well 2 miles south of La Junta at a depth of 1600 feet.

A second well is being put down at Manzanola, but the oil sand has not as yet been reached.

OURAY COUNTY.

Ouray production in 1902:

Gold.....	\$2,850,000
Silver.....	1,750,000
Lead.....	430,000
Copper.....	40,000
Total.....	\$5,070,000

Du Prau and others, leasing on the Grizzly Bear, near Ouray, have closed

down for the winter on account of snow.

B. H. Du Prau and Arps Bros. have a lease on the Eggleston group of five claims in Mount Sneffels district, between Ouray and Camp Bird.

The capacity of the concentrator at the Camp Bird, Ltd., near Ouray, has been increased by the addition of two Huntington mills.

PARK COUNTY.

Park county during 1902 produced: Gold (lode), \$150,000; gold (placer), \$100,000; silver, \$40,000; lead, \$35,000. Total, \$325,000.

The lessees on the Maverick, in the Badger mountain district, 8 miles from Lake George, have resumed sinking in the shaft, which is down 80 feet.

PITKIN COUNTY.

Pitkin county output for 1902:

Production of silver ore.....	\$1,800,000
Payroll per month.....	60,000

Number of men employed 700. The most important event of the year was the discovery of gold ore.

SAGUACHE COUNTY.

The Miner says the mill on the Crestone townsite will be remodeled by New York men for the treatment of Sunbeam ore. Concentrating tables will be put in. Miners are at work on the Sunbeam property.

SAN JUAN COUNTY.

The San Juan output in 1902 is reported:

Gold	\$2,100,000
Silver.....	1,000,000
Lead.....	300,000
Copper.....	100,000

Total.....\$3,500,000

A steam plant is being installed at the Silver Ledge mill at Chattanooga. The engine used at the old mill is being overhauled at the Gold King shops to be placed in the new mill. At the mine seventy men are taking out ore and opening new ground.

SAN MIGUEL COUNTY.

This county reports production for 1902 as follows:

Gold	\$1,800,000
Silver.....	1,100,000
Lead.....	100,000
Copper.....	50,000

Total.....\$3,050,000

The crosscut tunnel driven on the Butterfly-Terrill, near Telluride, several hundred feet below the old workings, has cut the lode and drifts are being driven both ways by two shifts.

SUMMIT COUNTY.

The mineral output for Summit county in 1902 was as follows:

Placer gold.....	\$150,000
Gold from ores.....	250,000
Silver.....	160,000
Lead.....	159,000

Total.....\$719,000

A gouge has been cut in the Marcelle Co.'s crosscut tunnel at Montezuma. This is considered evidence that the vein has been cut. The company is still driving the tunnel with the same force and better progress is being made. The company is figuring on machinery to be installed early in the spring, also a tram to convey the ore from the tunnel to the road where it can be shipped.

TELLER COUNTY.

At the Oil Creek tunnel, on North Oil creek near Gillett, Superintendent R. Lynch is crosscutting in the tunnel, which is in 300 feet.

The Bolivia Co., near Gillett, have resumed after an idleness of nearly two years. A few weeks ago their shaft house was burned, destroying the machinery, but a new and larger plant has been installed. The company expects to sink the shaft another 100 feet.

The total tonnage of Cripple Creek district treated by mills and smelters for December amounts to 55,700 tons, at an average of \$36 per ton, making a total of \$2,005,200. During the year the total number of tons of ore mined in this district and treated by mills and smelters amounted to 635,357 tons, having gross value of \$21,177,800. Dividends were declared during the year to the amount of \$2,170,522. Aside from this it is estimated that leasing companies and lessees, who keep their business private, made a profit of \$350,000.

At the mines of the Portland G. M. Co., Cripple Creek, besides the new battery of boilers and the air compressor, the company will install belt conveyors. Skips are to be used in the shaft, doing away with the cages. The work of sinking No. 3 shaft has passed the 1000-foot mark. Work has begun on the proposed drain-

age tunnel for Cripple Creek. The funds for the tunnel have practically been raised, chiefly among the mines along the west border. The tunnel will start from the southwest edge of the district and will run northeast, connecting with the El Paso shaft at a depth of 600 feet. From that point it will be run an additional 1000 feet, tapping the first main water course. It is expected that the draining of the district will be begun by the beginning of next October and will result in the further development of the Elkton, Moon-Anchor and Anchoria-Leland mines, and also greater activity in the El Paso, Mary McKinney, Gold King, Midget and other producers on the west side.

The Rocky Mountain Leasing Co., operating on the south end of the Delmonico, Cripple Creek district, are making steady shipments of ore of \$60 average value. This ore is being broken at the 200 level, where the vein of pay rock is 3 feet wide. A drift has been run 80 feet on it. A contract has also been let for 100 feet of additional sinking. A leasing company operating on the Dexter, on Bull hill, is taking out ore at the 300 level. Waldron and associates, leasing on the Chiclehawk, on Guyot hill, have cut the south extension of what they believe to be the Mary McKinney vein at the 600-foot level. The pay portion of the dyke is 4 feet in width and of smelting grade. An output of ten tons a day is being made. The lessees operating on the War Eagle are outputting forty tons daily. All the ore is being broken at the 60-foot level, where the ore body is 12 feet in width.

McDade and associates, leasing on the Pharmacist, Cripple Creek district, are breaking ore at the first and second levels in the old workings. A shipment of twenty-five tons was made last week. The Olympia Co. has resumed on block No. 7 of the Cameron townsite.

General Manager W. F. Rock, the Gold Sovereign M. & T. Co., Cripple Creek district, in his annual report says the main shaft was sunk 100 feet during the year, making it 550 feet deep. That portion of the property is under lease to the Cripple Creek & G. T. M. Co. The operators' lease runs to August 1, 1903. There are five sets of lessees and seven sets of sublessees operating on the company's property, employing in all forty men. Ore is being produced by three of the lessees and all of the sublessees. No work was done north of the shaft during 1902.

Superintendent Burch says work is resumed on the property of the Little Giant Co. in Pony gulch, Cripple Creek district. The company let a contract for 50 feet of sinking, which will make the shaft 150 feet deep.

President Neville of the Free Coinage Co., Cripple Creek, says ten leases have been granted on the Free Coinage estate. Among the principal lessees are Goldsworth and Wilhelm, who have a lease of one year on the Wilson claim, being an extension of one year; Shell & Co. a lease on the Pinto grounds; Lagstaff will work on the Pueblo claim of this company. All the leases extend for one year, and royalties are graded from 20% to 35%.

Three hundred men are at work on leases granted the first of the year. Mine owners believe that more work is done under the leasing system with better results for the company than under company direction.

At the Blue Flagon, Raven hill, Cripple Creek district, machinery, including a cage, has been bought. An old shaft is being enlarged and retimbered, while miners in another shaft are breaking and hoisting ore. When worked formerly the shaft was lost and for a long time the claim was idle. The vein now being worked is supposed to be the extension of the Joe Dandy.

During December the Golden Cycle mine, Cripple Creek district, made a total production of 3500 tons, the greater part being taken from the main workings, as the lessees were hindered by legal complications. The main shaft, which is down 925 feet, will be sunk to the 1100-foot point.

The output of the Independence Con. (Hull City placer), Cripple Creek district, is averaging 70 tons daily of \$40 ore. For December the output was 2000 tons from the company's workings and from leases on the ground away from the main workings. A contract is let for 200 feet of sinking. The present shaft is down 1150 feet. Two oil wells were opened up in the Florence field last week. Other wells are to be drilled.

Sinking is resumed on the Delmonico claim of the Union Co., Cripple Creek district, and the three-compartment shaft will be lowered to 500 feet. Until all the ore is stoped out above the 200-foot level to surface it is the intention of the leasing company to hoist the ore through the old shaft, down the hill, and which is connected with the three-compartment shaft.

The El Paso Con. M. Co. has the contract to drive the Cripple Creek drainage tunnel. Ore heading starts south from

the El Paso south drift and another will run easterly from the El Paso's northeast crosscut. As both of these headings will start in the El Paso mine, that company can use its air and steam lines and hoist the rock through its three-compartment shaft. Machinery will be installed in Arequa gulch, where a shaft is to be sunk to enable two headings to be started from there and also at the portal on Cripple Creek.

Horn & Archibald, leasing below the 200-foot level of the E. Porter Gold King, Cripple Creek district, have received returns on two carloads of ore that was settled for at \$30 per ton.

In prospecting the ground at a depth of 450 feet, J. Wright, operating the Thompson of the Elkton Con. Co., Cripple Creek district, is reported to have opened up the extension of the "hull pen" stope, worked in the fourth level south of the Elkton shaft.

Sinking is resumed on the Zoe, on Beacon hill, Cripple Creek, and will go down an additional 75 feet. The shaft is down 600 feet. The property is being worked by Best & Hanson, who have a bond and lease.

IDAHO.

ADA COUNTY.

The Five Bars M. Co., with headquarters at Boise, has been incorporated. The directors are E. Brannon, S. W. Roberts of Boise; A. E. Hostler, W. Eyre of Chicago; C. E. Whipple, Little Fiddler, Idaho; G. J. Porter, St. Louis. The properties are on Boise river.

BLAINE COUNTY.

At the Shamrock mine in the Smoky district, near Hailey, the tunnel is in 115 feet, and ore is being taken out which assays \$12 in gold.

CASSIA COUNTY.

S. McIntyre reports that at the Belcher mine, near Albion, in the tunnel being run to the main ledge at a depth of 1500 feet, at 1600 feet from the opening a cross ledge was cut showing values in silver, lead, copper and gold. Work continues as the main ledge is still ahead.

IDAHO COUNTY.

Superintendent B. Haug says the Dewey mill at Thunder Mountain is hung up till spring. Twelve men will work in the mine. The upper tunnel is in 200 feet and a winze sunk 30 feet from the tunnel. A flow of water prevented sinking to a greater depth. The lower tunnel will be driven 730 feet to the ore body and will be 100 feet under the upper tunnel. It is now in 360 feet. The Sunnyside Co. has sunk a shaft 180 feet. This company is running a tunnel to be 600 feet long, which will tap the ore at depth, and is in 300 feet.

OWYHEE COUNTY.

W. C. Orem and associates of Salt Lake City, Utah, have closed a deal for the Palmer group at Silver City. The group is on Florida mountain, adjoining the Trade Dollar.

Salt Lake people have taken the Palmer group of gold claims near Silver City. The prospects consist of seven claims on the extension of the Trade Dollar mine, and the consideration is \$50,000. It is the intention to form a company and develop the mine. W. Orem is manager.

SHOSHONE COUNTY.

The Park copper property, in the vicinity of Stevens peak, near Wallace, has its tunnel in 165 feet, and for the past 60 feet has been producing chalcopryite. The ledge is 25 feet wide, 6 feet of which is shipping ore. The tunnel is being run on the side of the ore chute and a crosscut driven every 20 feet.

The Little Giant, 2 miles south of Mullan, has resumed. There is galena showing in the upper tunnels, and another tunnel started on the east side of the mountain will tap the ledge at a depth of 500 feet. This tunnel will be 1000 feet long.

The Mullan M. Co., on its property in Deadman's gulch, 1 mile above Mullan, recently encountered a 5-foot ledge containing galena and copper ore.

The Little Chief, near the Hunter mine, at Mullan, is reported to have good ore and will put on an extra shift of miners.

The American-Commander, near Wallace, resumed this week; the company has let a contract for an extension of its tunnel 200 feet.

The Ajax M. Co. is rushing work in the tunnel adjoining the Hercules, near Wallace.—The Tamarack, north of the Custer mine, has cut the lead at a depth of 400 feet near the end of a 1000-foot tunnel. They found 4 feet of galena and carbonate ore. Another contract will be let.—The Snowstorm is making 100 feet per month on its lower tunnel.—Ore bodies have been encountered in the Tarbox and two shifts are drifting each way on the ledge. Work on the lower tunnel, known as

No. 6, at the Morning mine, near Mullan, has passed the 4000-foot mark. When completed, it will be 10,000 feet long, and it is estimated it will have cost \$150,000. The tunnel is 6x8 feet in the clear, and will cut the lead at 2400 feet below the cropplings.

It is reported the main shaft of the crusher at the Bunker Hill & Sullivan mill at Wardner broke last week, and it will probably be two or three weeks before repairs can be completed. The haulage of ore through the long tunnel had to be suspended. So as not to stop the operation of the mine entirely, the old tramway is being used. There is a small crusher at the end of the tramway, above Wardner.

The Oom Paul, a silver-lead property, above Burke, will resume, says H. J. Read, one of the owners.

Improvements to the extent of \$10,000 are to be made to the Northwest Sampling Works, near Wallace. The capacity of the plant will be increased to 1000 tons per twenty-four hours. Electric power from Spokane will be used.

Because the mining companies of the Cœur d'Alenes refuse to pay the taxes levied on the valuation of their mines, the county is unable to meet the payment of bonds to the amount of \$25,000. Some of the mine owners say they do not intend paying taxes and will fight the matter in the courts. The owners of the Hercules mine are the only ones willing to pay their taxes. The property of that company was assessed at \$50,000. The company, it is reported, was offered \$2,000,000 for the property. The other companies have already paid their taxes on the improvements on their property, which they have always paid. On most of the producing properties of the district the assessor assessed at \$500,000 each. Among these were the Bunker Hill & Sullivan, Empire State, Mammoth, Standard, Hecla and Morning. The Hunter was valued at \$200,000 and the Crown Point at \$100,000.

INDIANA.

During 1902 there were 3944 wells completed, of which 631 were listed in the gas well and dry hole column. The average production of completed wells is above that of any previous year in the record of the field. The daily production of crude oil of the Indiana field averaged between 24,000 and 27,000 barrels. Since operations for oil and gas were begun in the State there have been 22,252 wells completed, at an average cost of \$2000 each.

MONTANA.

BEAVERHEAD COUNTY.

A 15-stamp mill is at work on free-milling ore at Indian creek, near Wisdom.

It is reported that the mines of the Hecla Con. M. Co. at Glendale have closed until the price of silver advances to a point at which the property can be operated at a profit.

BROADWATER COUNTY.

Four men are at work in the Champion group at the head of White Horse gulch. At 500 feet from the mouth of a tunnel, in a 140-foot crosscut from the tunnel, a blind lead has been found 6 feet in width in which there is an 18-inch pay streak. The point where the lead was encountered is 175 feet below the surface.

S. Wisemiller says he has struck 6 inches of \$37 milling gold ore in the Lorna Doone claim in the Park district.

CARBON COUNTY.

It is reported F. W. Parker, G. Dygert and C. K. Gilfillen have bought the coal property at Joliet known as the Shanks mine. The railroad company will build a spur to the mine and development work will begin this month. T. Wilcher is superintendent.

DEER LODGE COUNTY.

The Ophir M. Co., which is working the Ophir mine in the southern part of Anaconda, contemplates sinking the shaft on the property 500 feet deeper, giving a total depth of 800 feet.

FLATHEAD COUNTY.

The Mustang Con. G. M. Co. has bought the Alabama group in the West Fisher district, near Libby.

Larson & Greenough, of Spokane, Wash., have taken a bond on the Banner & Bangle property, near Troy, in the Grouse Mountain district, which is close to the line between Montana and Idaho. The bond is to run a year and calls for the payment of \$50,000.

The Libby Placer M. Co. recently made a payment on the purchase price of the Howard brothers' placer ground on Libby creek. The property contains 1000 acres and two ditches, one of which conveys water from Libby creek to the diggings and the other from Ramsey creek.

Baeger & Scarlett have sold the Cedar group of claims on Libby creek, near

Libby, to Cleveland, Ohio, men for \$30,000. There are five claims in the group.

JEFFERSON COUNTY.

The Basin Reduction Co. has incorporated to operate at Basin. D. A. Howell, J. Maas, H. Smith, directors.

G. Benjamin and partners are developing a group of claims between Elkhorn creek and Boulder which contain manganese.

B. F. Forbes and A. M. Holters of Helena are shipping iron ore to Flinn station from their mine on Dry gulch, east of Elkhorn.

LEWIS AND CLARKE COUNTY.

Work on the Evening Star mine, in the Scratch Gravel district, 3 miles north of Helena, has reached the depth of 30 feet and a 30-foot tunnel run therefrom. A shipment of ore netted \$18 per ton in gold. The property is owned by E. R. Furnell and associates.

B. F. Forbes of Helena says he has arranged to open the Union mine, which is an extension of and joins the Holter lead.

The Columbian M. Co., operating in the York district, north of Helena, is installing electric motors to replace the ones destroyed by fire last fall. The motors will be operated by water power and will run the power drills in the Golden Messenger mine.

MADISON COUNTY.

The Chili M. Co.'s mill on Sand creek, 8 miles from Pony, is being torn down to be removed to Butte. The company is composed of Milwaukee men.

MISSOULA COUNTY.

Superintendent Short of the Tarbox mine, 2 miles from Saltese, reports a strike in the west drift about 150 feet from the double-compartment shaft, which has been sunk 225 feet. The last 40 feet of this drift showed from 5 to 7 feet of concentrating ore. He says the east drift is in 150 feet from the shaft and the lead is being crosscut. The Tarbox Co. will sink the shaft to open the vein to a depth of 325 feet.

The Copper Bell mines, near Clinton, says Superintendent Ketcham, will buy a diamond drill to prospect the property.

SILVER BOW COUNTY.

The hoisting plant of the Lexington mine, between Butte and Walkersville, was destroyed by fire on January 1; loss, \$50,000; no insurance; cause of fire unknown. The Lexington is a silver mine and has not been extensively worked for some years. A few months ago the property was sold to L. Giard.

A number of Butte miners who have previously won prizes in drilling contests are training for the contest to be held during the Mid-winter Carnival at El Paso, Texas, this month.

J. J. Barry, Deputy State Inspector of Mines, in his annual report on the mines of Silver Bow county, shows that the Amalgamated Co. has the greatest number of men employed and next in the list is the United Copper Co. Following is a table showing the number of men employed at the Amalgamated properties:

	Top Miners.	Engi- Men. neers.
Anaconda.....	2,356	468
Boston & Montana..	982	153
Butte & Boston.....	464	83
Parrot.....	320	66
Colorado.....	350	26
Washoe.....	125	30
Total.....	4,597	826

The grand total of the Amalgamated Co., exclusive of the lumber yards, Butte & Boston and Colorado smelters, is 5497.

The appended table shows the number of men employed at each of the mines of the Heinze properties, exclusive of the employees of the smelter:

	Top Miners.	Engi- Men. neers.
Rarus mine.....	420	55
East & West Cora....	200	25
Nora.....	59	20
Total.....	679	100

W. A. Clark employs 615 men at his mines, and 250 men at smelter, making a total of 865 men.

The totals:
Employed at Amalgamated mines.. 5,497
Employed at Heinze..... 788
Employed at Clark's mines..... 615
Other mines..... 275

Total.....	7,175
Number of employees in the lumber yards and the two smelters of the Amalgamated.....	525
Number of employees at the Heinze smelter.....	150
Number of employees at Clark's smelter.....	150
Total.....	925

Total of all men employed at both mines

and smelters and lumber yards, 8100.

During the period covered by the inspector's report there were thirty-three men killed in the mines of Butte and forty-two accidents to employes that were not fatal.

The Sailor's Dream mine and mill, 14 miles northwest of Butte, owned and operated by A. Barton and P. Kendrick, is closed till spring. Owing to a scarcity of water in the gulch in which the mill is located, no runs have been made this winter.

J. S. Harris, receiver of the Snohomish and Tramway mines at Butte, has filed his thirty-third monthly report in the United States Court. Unlike former reports, this one shows that in November there were no receipts, while expenditures amounted to several thousand dollars, due to the recent decision of the Circuit Court at San Francisco, Cal., which had the effect of closing down the two mines pending a further hearing of the suit between the Boston & Montana M. Co. and F. A. Heinze.

NEVADA.

ELKO COUNTY.

Manager A. Carlson of the Deer Creek mine, near Charleston, says he will put up a stamp mill having a capacity of fifty tons per day. The property is 45 miles northeast of Tuscarora and 8 miles east of Gold Creek, and carries gold-silver ore running \$25 per ton.

LINCOLN COUNTY.

At the Rambler mine, at Searchlight, Superintendent C. E. Maud says the 22 H. P. gasoline hoist is in operation, and sinking is resumed in the shaft.

The double-compartment shaft on the Green Monster mine at Sandy is down 175 feet and in ore. This mine is owned by the Hearst estate. F. O. Wilkinson is superintendent.

LYON COUNTY.

At the Mazuma mine in Pumpkin Hollow, near Yerington, Glines, Cavanagh & Clark are drifting north and south on the 150 level. The ledge is 2 to 3 feet in width and the ore will average \$20 per ton. Shipments will begin in the spring.

The Silver City M. & Drainage Co. has men at work enlarging the Daney tunnel, the ultimate object of which is the drainage of the Silver City and Devil's Gate districts mines.

NYE COUNTY.

The McNamara Co. have let a contract to sink their main shaft 1000 feet, and to drive 600 feet of crosscuts at the 500 and 1000 levels when reached.

The Indiana-Tonopah, near Butler, whose properties adjoin the California-Tonopah on the north and east, has begun a double-compartment shaft. The contract for buildings was let last week. F. Dunn is superintendent. At the Golden Anchor, northwest of the Mizpah, the shaft is down 100 feet in gray porphyry containing seams of quartz. J. Y. Kane is superintendent.

The 50 H. P. boiler and engine of the West End Co., near Butler, are being set up, and next week sinking from the 200 station to 500 feet will begin. Work on the Rescue Co.'s property began last week with M. Sheridan as superintendent—enlarging the shaft to a double-compartment. The main shaft of the Halifax, 1 mile east of Mount Oddie, is down 300 feet and crosscutting begun. At this depth water has been encountered. The main shaft of the Tonopah Chief is down 45 feet in mineralized porphyry. At present a whim is being used for sinking, but a steam hoist will be put in.

STOREY COUNTY.

At the Con. California & Virginia, Virginia City, the total extraction of ore for the week ending Jan. 3 was eight cars, assaying \$48.76, and 147 cars, assaying \$21.12. At the Hale & Norcross the tunnel was advanced 12 feet during the week; total length, 3362 feet. The face is in diorite.

WASHOE COUNTY.

A group of claims at Olinghouse is reported bonded to J. J. Mahoney of Wadsworth. A double-compartment shaft will be sunk to develop the group.

WHITE PINE COUNTY.

J. A. Traylor, manager the New York & Nevada C. Co. mine, near Ely, shot and killed J. Staggs, J. Smith and S. Johnson and severely wounded three others when attacked in his office at Keystone on the 7th inst. by several men said to be members of the Miners' Union. The shooting was the outcome of the strike declared against the company several weeks ago owing to wages being cut from \$3.50 to \$3 a day. The men claimed that Traylor was responsible for the reduction, and it is said that threats were made against his life. Traylor received information that he would have to leave

town. He announced that if assaulted he would defend himself. Traylor was in the company's office at Keystone when the men entered with the avowed intention of running him out of camp. One of them grabbed him by the throat while several others caught him from behind. Traylor broke away from his captors, drew his revolver, and fired six shots. The uninjured men ran out of the office after the shooting, leaving three dead and three wounded on the floor. Traylor's home is in Denver, Colo. He was employed by the copper company at Durango, Mexico, previous to taking charge of the mine near Ely.

NEW MEXICO.

GRANT COUNTY.

Shipments have been resumed from the Granite Cap, near Silver City. An effort has been made by the owners to have freight rates and treatment charges reduced.

The Beck mine has been bought by the National G. & S. M. Co. for \$5000.

OREGON.

BAKER COUNTY.

Superintendent L. Walker of the Cracker-Oregon mine, near Baker City, reports that calaverite has been struck in the Cracker-Oregon. He is sinking on the ore shoot. The shaft will be double-compartment, the foundation for the hoist being already laid and the gallowes frames up.

D. Grant and J. Bumgardner of Bourne have sold to J. W. Hughes, F. S. Shaw and A. Saylor of Seattle for \$11,500 the Porcupine, Greenback, Victor and Victor Fraction claims, 1½ miles from Bourne.

BAKER COUNTY.

The Black Jack group, near Sumpter, is reported sold to Nebraska men. This group is south of the Red Boy mine and is the southern extension of the Oregon Monarch group.

The Oregon S. & R. Co. have 100 men at work on the buildings of their smelter being erected at Sumpter. The sampling mill of 700 tons daily capacity is partially completed and the foundations for the ore bins are laid. The dust chambers are finished and the steel smoke stack, which will be 130 feet high, is going up.

Manager O. Townsend of the Baby McKee and Last Chance mines in Cable Cove district says a two-compartment shaft 4½ x 9 feet is being sunk at the junction of the Eagle and Last Chance veins and is down 55 feet. A crosscut is being run to the hanging wall. After this work is finished the shaft will be sunk to 100 feet and a drift run under the old tunnel. The Bonanza mill at Geiser is dropping twenty stamps. A crosscut from the 850 level of the main shaft has cut the ore body.

GRANT COUNTY.

Near Susanville, Hughes & Sanderson have opened up a 6-inch vein of free-milling ore at a depth of 50 feet. The entire ledge is 24 inches. The claim lies north of the Badger mine and near the mill built by the Badger Co. The Badger Co. put a pump in the Bull of the Woods last week where they have a 20-foot ledge of ore. W. Cooper sold to N. C. Haskell of Baker City his one-half interest in the Monarch and Oreolo quartz claims. Graham & Heaton Bros. have begun work on the Daisy. Smith Bros., at the Princess mine, have cut a 4-foot ledge at 60 feet in the shaft.

The Old Arastra M. Co., whose property is on Granite creek, 4 miles north of Granite, have decided to drive the tunnel 50 feet farther and upraise to the crosscut tunnel 96 feet above. It is also the intention to run a crosscut tunnel west.

JACKSON COUNTY.

J. W. Coffman has sold 240 acres of placer ground on Forest creek, near Ashland, to E. A. Spaulding et al. of Tacoma for \$10,000.

The Hicks quartz mine on Blackwell hill, near Medford, is reported sold to C. A. Greigson of Gold Hill.

JOSEPHINE COUNTY.

J. Shaska and P. Robinson have bonded their property in Owl Hollow, east of Grants Pass, for \$40,000 to Colorado men represented by T. J. Pearce of Gold Hill.

East of Baker City, near Medical Springs, development work has been in progress at the Sanger mine under management of J. K. Romig. Some time ago the property was sold to Eastern people. A company has been formed to be known as the Sanger Gold Mines Co. President, F. W. Paine, Walla Walla; superintendent, J. K. Romig. The company has bought water rights on upper Eagle creek and early in the spring will install an electric plant operated by water power.

PENNSYLVANIA.

PAYETTE COUNTY.

On the 2d inst. the abandoned workings of the Eddy creek colliery beneath the town of Oliphant caved in and engulfed four buildings. The loss is \$40,000. No one was killed.

LUZERNE COUNTY.

A further increase in the number of men in the mines is reported by coal companies throughout the region. There are now 85% working. The operators are urging the men and more coal is being mined per man than at any other period in the history of coal mining.

SOUTH DAKOTA.

CUSTER COUNTY.

A strike of gold ore is reported on the Roosevelt group of the Grantz G. M. Co., 8 miles from Custer, in a drift started from the bottom of an old shaft, half a mile from the main shaft, near the southwest corner of the Roosevelt group. The ore is said to contain free gold and sylvanite.

LAWRENCE COUNTY.

According to the most reliable report, the mines of the Black Hills produced \$3,373,392 during 1902. The output for December is estimated on the basis of production of November. The gold product for 1901 was \$7,500,000. Following is the table of tonnage and production of mines for 1902:

Mine.	Tons Milled.	Gold Values.
Homestake.....	1,339,200	\$4,663,930
Golden Reward....	177,800	1,393,000
Horseshoe.....	62,100	760,510
Imperial.....	50,600	220,000
Spearfish.....	47,206	211,030
Holy Terror.....	17,800	206,000
Dakota.....	44,032	174,000
Lundberg & Dorr..	18,720	116,000
Clover Leaf.....	24,480	98,300
Wasp No. 2.....	31,000	93,200
Portland.....	12,000	84,000
Alder Creek.....	13,822	59,428
Hidden Fortune.....	45	45,000
Deadwood-Stand'rd	10,289	40,444
Columbus (3 mos) ..	3,850	38,500
Golden Slipper....	3,000	20,000
Placer (est.).....	100,000
Intermittent producers.....	5,000	50,000
Total.....	1,860,944	\$8,373,342

The average value per ton was \$4.44. The output will be increased from 30% to 40% by six new cyanide plants now in course of building. These plants will be running before March 1. Following are the new mills and their respective monthly capacities:

	Tons.
Horseshoe.....	30,000
Hidden Fortune.....	7,500
Penobscot.....	6,000
Jupiter.....	4,500
Hall & McConnell.....	1,800
Golden Crest.....	1,500
Total.....	51,300

The Penobscot 40-stamp mill, near Deadwood, is in operation. The cyanide process is used. F. R. Byrnes is superintendent. The Golden Crest cyanide mill and cyanide plant, near Deadwood, is in operation. These two plants will add 200 tons to the daily amount of ore treated in the county.

At Garden City, the Penobscot M. Co. cyanide plant and mill are in operation.

UTAH.

The mineral output of Utah for 1902 is estimated as follows:

146,978,597 pounds lead, at 4 cents per pound.....	\$ 5,879,143 88
26,373,780 pounds copper, at 11.59 cents per pound....	3,048,608 10
15,692,733 ounces silver, at 52.15 cents per ounce.....	8,160,325 84
194,863 ounces gold, at \$20 per ounce.....	3,897,260 00
Total.....	\$20,985,337 82
Production for 1901.....	17,580,457 88
Increase for 1902.....	\$ 3,404,879 94

BEAVER COUNTY.

Foreman C. Price of the Old Hickory mine at Milford reports a strike of copper ore at 200 feet in the tunnel.

The ledge in the Erie mine, near the O. K., has been cut at the bottom of the shaft, down 132 feet. The shaft will be continued to 150 feet, when drifting will begin.

Manager B. T. Lloyd of the Copper Ranch and Copper Mountain Co.'s mines, near Milford, says operations will be resumed. A gasoline hoisting plant will replace the whim on the Jewel Mound shaft, and later another hoist will be in-

stalled on the east end of the property. At the Copper Mountain it is intended to sink the vertical shaft deeper, which is now down 230 feet.

moth mine, Tintic district, in a section of the mine hitherto unexplored, being to the west of the old workings.

A strike is reported in the north drift from the 1000 level of the Ajax at Mammoth.

PIUTE COUNTY.

Manager B. Luce of the Mt. Baldy mine at Marysville has let a contract for 100 feet of tunnel work.

BOX ELDER COUNTY.

The Brooklyn of Pine canyon, Park Valley district, has been bonded to Wisconsin men.

JUAB COUNTY.

Manager McIntyre of the Mammoth at Tintic says the repairs to the hoist are completed and operations at the mine resumed.

Ore is reported opened up between the 1100 and 1200 levels of the Lower Mam-

SALT LAKE COUNTY.

Near Bingham, at 330 feet in depth, on the Zelnora's incline, a drift is being run easterly in carbonate ore carrying copper, lead, silver and gold. It is expected that the Frisco tunnel will cut the Zelnora vein at 1200 feet. The tunnel is in 900 feet.

The Big Mitt G. M. Co. is incorporated to operate the Pacific mining claim in Little Cottonwood district, near Alta. G. C. Kittle, A. W. Clayton, E. H. O'Brien, W. J. and D. Wolstenholm directors.

The Chloride Point mine, near Salt Lake City, has resumed, says H. Brown, who controls the property, and two shipments have been made.

W. H. Tibbals says he has bought the Papea and Trida, two patented claims at Bingham. These two claims are near the Dewey mill.

Manager J. A. Jacobson of the Centennial of Bingham says a body of galena ore was struck last week in a drift which is being run 400 feet from the mouth of the tunnel.

SUMMIT COUNTY.

Foreman McDonald of the Little Bell, near Park City, says the shaft is down 450 feet. He is raising and drifting from the 300 level. The drift is in ore.

Superintendent Rood, the Ontario mine, Park City, says the force has been reduced by one-half, but there is no intention of ceasing operations. "In 1901 we thought that the price of silver had reached as low a point as would permit a reasonable profit from mining our ores and selling them to the smelter under our contract. The annual report showed a net profit of 12 cents per ounce of silver on ore mined. Yet the present quotation is 10 cents lower than our average sale price for 1901. It has been considered advisable, therefore, to discontinue the extraction of ores until existing conditions are bettered. There is yet a large tonnage to be taken out above the 1500 level, and no ore has been extracted below it, except in the drifts and raises. Development of the mine between the 1500 and 2000 levels will be continued."

The hoisting plant at the Creole at Park City is in operation.

UTAH COUNTY.

It is reported S. A. King has bought the Deseret mine in the Gold Mountain district, near Provo, for \$20,000. The property consists of seven unpatented claims.

WASHINGTON.

FERRY COUNTY.

Superintendent J. C. Cale says the tunnel on the Nova group, southeast of the Mountain Lion mine, near Republic, is in 250 feet, passing through quartz and stringers of spar in porphyry.

OKANOGAN COUNTY.

At Nespelem Wheeler & Chapman of Vermont will install a custom mill on the Hattie E. early next spring. E. K. Jacobs has been working on the Kickapoo, employing four men on a contract, and has been making 2½ feet per day. They are in ore that runs \$30 in gold and silver. The property has been bonded by Jacobs & Brown to A. D. Walker of Seattle. Dr. Hudnutt is working six men on the Multnomah claim and will drive a tunnel to tap the veins at depth. He is taking out ore.

The Ventura group of eight claims has been bonded by Hollis & Hunter of Spokane. The Ventura group is on Robinson creek, in the Methow district, on the line of the proposed Methow railroad.

The Ben Harrison group, near Chasaw, has been bought by the Opal M. Co. of Ohio for \$25,000. It is a copper proposition carrying gold values.

SNOHOMISH COUNTY.

The tunnel on the Toledo, owned by J.

Walter, on Granite peak, near Index, is in 70 feet and shows copper, gold and silver ore. The formation is quartzite.

At the Golden Rule claim of the Golden Eagle M. & D. Co. above Mineral City, the work on the new tunnel and black-smith shop 300 feet below the present tunnel has been started. On the Mountain Beauty an open cut has been made, showing the ledge. On the King William two tunnels each 45 feet on the ledge have been driven.

WYOMING.

H. C. Beeler, State Geologist of Wyoming, says in his annual report for 1902 in the past five years over 500 miles of wagon roads connecting various camps in southern Carbon county alone have been made, of which 300 miles were built in the last two seasons. There are nineteen recognized oil fields, of which twelve are being developed. The largest field is located in the Salt Creek district of Natrona county, where the Pennsylvania Co. has thirteen producing wells and owns the only refinery in the State.

CARBON COUNTY.

The Elkhorn mine in Whisky park, near Dillon, is reported bonded and sinking is resumed.

The Northwestern Co. is sinking an incline shaft on the Eclipse on Cow creek, near Dillon. The shaft is down 90 feet and is following a vein of copper ore. A. Woodruff is superintendent.

A vein of coal 3 feet in width has been encountered in a tunnel of 130 feet by the Carbondale Coal Co. at Carbondale. The new coal bin is 20x40 feet in size with a capacity of 200 tons. The tippie will be 68 feet high.

CONVERSE COUNTY.

Work has been resumed on the Aetna, near Beaver, with R. Daniels in charge.

LARAMIE COUNTY.

A syndicate of London and Denver men is said to have bought the onyx quarries at Hartville, in the northern part of this county. Two carloads of this onyx were recently shipped to Denver.

FOREIGN.
BRITISH COLUMBIA.

(Special Correspondence) — Notwithstanding the drawbacks of the past year, for which neither mine owners nor mine workers were responsible, the year 1902 has shown a decided advance in the Boundary district, both as regards the amount of development work and the results as shown by ore shipments from the mines.

The records show that in the year 1900 — the year that the C. P. railroad completed its branch line into the Boundary — a little short of 100,000 tons of ore were sent out from several shipping mines. In 1901 the shipments increased nearly four fold, the total being a few tons short of 390,000 tons for the full twelve months. In 1902, the figures for the last few days being estimated, as the figures are not yet made public, the total is over 500,000 tons.

Had it not been for the events following the explosion in the Fernie coal mines in East Kootenay in May, whence the only coke supply can be obtained at a price that will admit a profit on these ores when smelted, there is reason to believe that this record would have been much larger.

Throughout the year a few mines have been regular shippers from Boundary district. Six of these have shipped steadily and have been locally known as the "Big Six." They are the Granby and Snowshoe in Phoenix camp, the Mother Lode and Sunset in Deadwood camp, and the Emma and B. C. in Summit camp. The only one of these that has shipped every week of the year is the Granby, although the Mother Lode can show a nearly similar record.

In relative importance, as shown by the tonnage, these mines may be placed in the following order: Granby, Mother Lode, Snowshoe, B. C., Sunset and Emma. Three of these have shipped only to their own smelters, namely, the Granby, Mother Lode and Sunset.

Granby, Phoenix camp, 319,713 tons; Snowshoe, Phoenix camp, 21,153; Mother Lode, Deadwood camp, 144,671; Sunset, Deadwood camp, 11,615; B. C., Summit camp, 15,024; Emma, Summit camp, 11,478; Winnipeg, Wellington camp, 785; Golden Crown, Wellington camp, 625; No. 7, Central camp, 482; Jewel, Long Lake camp, 2175' sundry small shipments, 2300. Total for 1902, 520,026.

The month of December shows the largest tonnage of any single month, notwithstanding that three of the seven blast furnaces in local smelters were cold a part of the month. About 60,000 tons were shipped during December, the next largest month being October, when 55,000 tons were sent out.

During the year 1902, two of Boundary's

three smelters—the Granby and Mother Lode—were running continuously for the twelve months, with the exception of the time when coke supplies were cut off in summer. The Sunset smelter began operations about the time that coke supplies failed, but this has also run steadily since coke was steadily forthcoming.

The Granby smelter is located at Grand Forks, having four blast furnaces, two copper converters which handle the matte from the other two Boundary smelters also. Two additional furnaces have been ordered recently in Chicago, which will give a capacity for these works of 2200 tons of ore daily. This smelter takes little custom ore, with the exception of some from Republic, in Washington, largely used as converter linings.

The Mother Lode smelter is at Greenwood and has two blast furnaces. Two more furnaces will be added the coming year. Mother Lode and some custom ores are reduced at this smelter, including those of the Snowshoe and B. C. mines.

The Sunset smelter at Boundary falls, 4 miles below Greenwood, was originally built by the Standard Pyritic S. Co., but was not blown in till bought and remodelled by the Montreal & Boston C. Co. last spring. The same company owns and operates the Sunset mine in Deadwood camp, taking also ores from the B. C. and Snowshoe mines. The Sunset smelter has one furnace and is installing a second, to be ready in January, and has placed the order for a third.

Boundary mines have not yet gotten to the stage where dividends have been paid. As is usual with low-grade properties, it requires years of preparation and the investment of large capital to reach this point, but several promise to enter the dividend class this coming year. Nothing official has been given out as to the values of the ores. The ore of this section is nearly all of the copper-gold variety and low grade—but there are mountains of it, so that the expense of extraction is reduced to the minimum. The values have been estimated at \$4 to \$6 per ton; \$5 is probably a fair average. On this basis the mines of the Boundary have produced during the year ore that is valued at \$2,500,000.

A few mines have been developed during the year showing high values, notably the Providence, near Greenwood, from which a few cars have been shipped, running from \$100 to \$150 per ton. But the general run of the ore is low, and it is only by using the best modern equipment in mines and smelters that the properties can be made to reach a paying basis, as it is now believed they have. One feature of the mining development the past year is the system of open quarrying of ore. By this plan all hoisting is done away with, the ore being broken down and run through chutes or by trams to the railway by gravity.

Phoenix, B. C., Jan. 2.

The combined output for the three principal districts of British Columbia for 1902:

	Tons.
Rossland.....	319,714
Boundary.....	520,026
Slocan.....	28,429
Total.....	868,169

The ore shipments from Rossland camp for 1902, being the dry tonnage returns from smelter reports, were:

Mine.	Net Tonnage.	Est. Gross Value.
Le Roi.....	202,530	\$2,600,000
Le Roi No. 2.....	52,500	800,000
Center Star.....	35,820	437,004
War Eagle.....	21,819	334,048
Rossland G. W.....	2,400	36,000
Giant.....	2,850	42,000
Cascade.....	300	4,000
Kootenay.....	30	300
Bonanza.....	90	1,500
Velvet.....	1,350	25,000
Spitzee.....	20	400
White Bear.....	5	100
Totals.....	319,714	\$4,280,352
Total for 1901.....	279,133	

The following is the payroll for 1902, which the Miner says is accurate with respect to the big mines and estimated in the case of the smaller properties, from which actual figures were not obtainable:

Le Roi.....	\$ 463,150
Le Roi No. 2.....	214,500
Center Star.....	168,397
War Eagle.....	123,913
Rossland Great Western.....	50,000
White Bear.....	18,000
Kootenay.....	15,000
Giant.....	5,000
Velvet.....	50,000
Spitzee.....	3,000
Cascade and Bonanza.....	5,000
Other mines.....	5,000
Total.....	\$1,120,960

The Slocan ore shipments for 1902, with average value of ore per ton, were:

	Tons.	Av. Val.
Payne.....	1,976	\$100
Ivanhoe.....	637	75
Sunset.....	827	125
Reco.....	490	250
American Boy.....	1,134	50
Arlington.....	3,560	150
Hewett.....	805	40
Bosun.....	2,040	65
Last Chance.....	168	75
Wonderful.....	181	90
Enterprise.....	2,220	50
Queen Bess.....	180	75
Silver Glance.....	257	250
Whitewater.....	2,962	40
Slocan Boy.....	158	80
Neepawa.....	123	40
Monitor.....	1,306	80

Wakefield.....	220	50
Rambler.....	4,187	75
Molly Gibson.....	2,100	60
Washington.....	187	80
London Hill.....	115	100
Ruth.....	846	100
Antoine.....	207	100
R. E. Lee.....	144	80
26 small mines (total).....	685	...

Total.....28,429

The Osoyoos & Similkameen Coal & Exploration Co. of Spokane, Wash., has secured 6400 acres of coal land in the Similkameen country, and will start development work in the spring. The company has also secured the Princeton townsite.

The Fern mine at Hall Siding, near Ymir, has been bonded to E. Rammelmeier.

New agitating tanks are being installed at the Bullion Extraction Works at Silica.

The Gold Coin P. & D. Co., at San Javier, have their fifty-ton smelter running. The fuel used is the natural coke from La Barranca, obtained 4 miles distant, which is delivered at \$7.50, Mexican, per ton. Some of their ores require concentrating, and a plant for that purpose will be put in.

An option has been given on a one-third interest in the Spotted Horse group near Ymir to E. Cole of Portland, Ore.

The Standard Development Syndicate, of Nelson men, has been formed to operate the Hunter V. mine, on the divide between Porcupine and Hidden creeks. The property consists of the Hunter V. and the Double Standard claims.

KLONDIKE.

There are fifty litigants over claim No. 4 in Lovett gulch at Dawson. The Gold Commissioner has the matter under advisement. The ground was staked in three ways. One class of stakers, the plaintiffs, planted their posts on the base line, claiming 250 feet up and down stream. Others staked on the right limit and claimed 1000 feet as hill property. The majority of the claimants staked in this manner. Some others staked the property as a fractional claim. Forty out of the fifty claimants gave testimony to establish their particular claims. The number testifying was the greatest ever participating in one case in Dawson's Gold Court. The Gold Commissioner will take several weeks to go through the mass of testimony before deciding which miner is entitled to the property. The claim pans well in gold all over the surface and was the central location in one of the fall stampedes.

MEXICO.

SINALOA.

A new mining district is being developed 40 miles southwest of Tierra Blanca. Two hundred American miners have within the past month gone into the section.

SONORA.

Near Bacoache a strike upon the extension of the Picacho gold property is reported. An American bought it from a Mexican for a small sum. At 103 feet the vein was cut. Assays give similar values to those from the Picacho.

President W. C. Greene, the Greene Con. C. Co., at Cananea, says the company is planning to double the capacity of the plant, which will give when completed a capacity of from 12,000,000 to 15,000,000 pounds of copper per month. A contract has been let for a 10-inch pipe line, 10 miles long.

The Cananea Herald reports the gold mines in the Pilares de Capteras, 60 miles south of Douglas, bonded by W. C. Greene for \$250,000, have been abandoned by him and have been sold by their owners to a Philadelphia corporation for \$300,000. It is stated that twenty men are at work there taking out ore.

SOUTH AFRICA.

A correspondent of the London Daily Mail reports that large and rich diamond fields have been found north of Pretoria.

PERSONAL.

FRANK LONGMAID of Montana is in Oakland, Cal.

DANA HARMON has returned to San Francisco, Cal.

W. DAVIES is assistant superintendent of the Lightner mine, Angels, Cal.

W. A. GABLE is manager the Little Flat mines near Idaho Springs, Colo.

J. N. HAMILTON of the Dewey mines, near Ibapah, Utah, is in Chicago, Ill.

C. PETERS of the McNamara mine, Tonopah, Nev., is in San Francisco, Cal.

W. BECK is superintendent at the Black Jack mine at Diamond, Juab county, Utah.

S. CURTIS, secretary of the King M. Co., Phoenix, B. C., is in New York City.

H. W. DURRELL is now chemist for the Avino Mines of Mexico at Durango, Mexico.

B. HAUG, superintendent Dewey mine, at Thunder Mountain, Idaho, is in Boise, Idaho.

SUPERINTENDENT CRANE of the Wedekind mine, near Reno, Nev., has resigned.

PRESIDENT J. DERN of the Con. Mercur M. Co., Mercur, Utah, is visiting in Nebraska.

SUPERINTENDENT F. CHAPPELLET, the Mohican mine, near Groveland, is in Oakland, Cal.

MANAGER G. B. UPTON of the Oro Grande mine, near Wickenburg, Ariz., is in the East.

A. WANBERG of Kodiak, Alaska, has returned to his mines there from San Francisco, Cal.

R. BELL, State Mine Inspector of Idaho, has returned to Boise from a visit to Salt Lake City, Utah.

T. WILCHER is superintendent the Shanks coal mines at Joliet, Carbon county, Montana.

J. A. MCINTYRE, of the South Keystone mine, near Sutter Creek, Cal., is in San Francisco, Cal.

J. K. ROMIG, superintendent Sanger gold mines, Medical Springs, Or., has gone to Milwaukee, Wis.

W. C. RALSTON, manager Melones M. Co., Melones, Calaveras Co., Cal., has returned from Boston, Mass.

MANAGER A. CARLSON, the Deer Creek mine, has returned to Charleston, Nev., from Salt Lake City, Utah.

B. HASTINGS, superintendent the Ramrod group of mines near Kingman, Ariz., has returned from the East.

J. W. SKELTON of Tonopah, Nev., is examining placers in the Hassayampa district, south of Prescott, Ariz.

SUPERINTENDENT MCMAHON, the Butte mine, near Randsburg, Cal., has returned from San Francisco, Cal.

E. M. MESSITER is superintendent Gowers Mine Syndicate operating the Pierce mine, near Central City, Colo.

F. E. WARE, superintendent of the Mount Shasta mine, near Redding, Cal., has returned from San Francisco, Cal.

W. L. WATTS has returned to Los Angeles, Cal., from Carters, Cal., where he has been making mine examinations.

J. R. CUNNINGHAM, secretary the Advance and Forest M. Cos., Sumpter, Or., goes East on business for both concerns.

C. F. BUNKER goes to Prescott, Arizona, near which place he will build a cyanide plant for the Golden Link M. Co.

H. S. ANDERSON, manager of the Shannon Copper Co., has returned to the mine, Clifton, Ariz., from Los Angeles, Cal.

R. W. ATWATER of London succeeds J. R. Robertson, deceased, as general manager the Ymir Mines, Ltd., at Ymir, B. C.

EDGAR KIDWELL, representing the Stirling Boiler Co., transfers his office this month from San Francisco to Denver, Colo.

L. D. RICKETTS, consulting engineer for the Greene Con. Copper M. Co., Cananea, Mexico, was in Los Angeles, Cal., last week.

W. CLIMO, superintendent of the Shannon mines, near Clifton, Ariz., has returned from a three months' trip through California.

L. HANCHETT has returned from Pittsburgh, Pa., where he had been in the in-

terest of the Old Town and Calumet, to Idaho Springs, Colo.

C. T. DURELL of Lewistown, Mont., is at his former home in Denver, Colo. Mr. Durell is manager Central Montana M. Co., operating in Fergus county, Mont.

A. G. LARSON, superintendent the Nickel Plate and Kootenay mines since November, is general superintendent the Rossland-Kootenay M. Co. at Rossland, B. C.

G. V. HOPKINS has resigned the management of the Bullion Extraction Works at Silica, B. C. Mr. Hopkins leaves for England this week. He is succeeded by C. M. Eye, late of Aspen, Colo.

THE annual election of officers of the California Academy of Sciences for 1903 was held at San Francisco on the 5th inst. W. Alvord was elected president, to succeed D. S. Jordan; A. Bull, vice-president; H. H. Behr, second vice-president; J. O. B. Gunn, corresponding secretary; J. W. Hobson, recording secretary; L. H. Foote, treasurer; L. Falkenau, librarian; L. M. Loomis, director of the museum; W. M. Pierson, J. F. Houghton, W. H. Crocker, C. E. Grunsky, E. J. Molera, G. C. Perkins, G. W. Dickie, trustees.

Obituary.

CHAS WESSEL, the metallurgist, died in New York City January 3, 1903. Deceased was 65 years of age.

JAMES HUTCHINSON, formerly manager of the Trade Dollar mines at Silver City, Idaho, died at Boise, Idaho, Dec. 31, 1902, of apoplexy. Mr. Hutchinson was 65 years of age and was widely known throughout the West as a mining man. For twenty years he was superintendent of the Gregory mine, in Gilpin county, Colo., and afterward superintendent of the Aspen mine at Aspen, Colo. In 1889 he was appointed State Mine Inspector for Colorado. Mr. Hutchinson was a native of Cornwall, England.

HENRY A. VEZIN died in Denver, Colo., Dec. 27, 1902, of angina pectoris. He was educated in Germany. Served throughout the Civil War in the Ninth Pennsylvania cavalry. At the close of the war he went to Colorado. During the past fifteen years he had an office in Denver, where he acted as consulting, mining and mechanical engineer. His advice on sampling and smelting machinery was much sought after. He was the inventor of the Vezin sampler. He was eminent in his profession and noted for his thoroughness in everything he undertook. The remains were taken to Philadelphia, the city of his birth, for interment.

Commercial Paragraphs.

N. B. LIVERMORE & Co. remove from 320 Sansome street, San Francisco, Cal., to the Rialto building, February 1.

THE S. S. Machinery Co., Denver, Colo., has an order for a 10-stamp mill complete, boiler, engine, etc., from the Southern Mexico G. M. Co.

ON New Year's Day, the Canton Steel Co., 1621-1639 Seventeenth St., Denver, Colo., kept open house to their friends. Refreshments were served to several hundred guests. Mr. P. P. Bush, Western manager, reports a most satisfactory business for 1902.

FAWCETT & WOOD of New York, who have been on the Comstock, have contracted with Superintendent Kinkead for one of his mills of 25-ton daily capacity, to be installed on mining property at Downeyville, Nye Co., Nev., of which they are the owners.

THE S. H. Supply Co., Denver, Colo., has recently purchased the compressor and boiler plant of Portland G. M. Co., Victor, to make room for a larger outfit, and also dismantled two electric light plants at Manitou, Colo., which they now have in their warehouse in Denver.

THE Austin Mfg. Co. of Chicago have recently installed a large crushing plant for the California Portland Cement Co., Los Angeles, Cal., consisting of a No. 3 and No. 6 crusher. The California company say that they now have the most complete crushing plant of the kind on the Pacific coast.

THE Colorado Iron Works Co., Denver, Colo., has orders for two reverberatory furnaces, 16x64 feet, for the Ohio & Colorado S. & R. Co., Salida, Colo.; one 36-inch round copper matte furnace for Tacoma Smelting Co., Tacoma, Wash.; one 5-stamp mill complete, and three Frue vanners for El Carmen Copper Co., Durango, Mexico.

Catalogues Received.

From the American Engineering Works, Chicago, is received a further installment of their handy cataloglets, on switches and trackwork, Amew hose, coupling, never-slip car movers, perfect wheels, self-oiling axles, trommel and heavy screens, any of which will be sent on request from mining men.

The Allis-Chalmers Co. of Chicago have issued Catalogue No. 5 on Rock Crushing Plants, which is up to the standard of former catalogues on this subject. It deals with rock breakers, revolving screens, elevators and conveyors, and gives sectional drawings of construction of several concentrating plants, together with much information on the subject of crushing and sizing of rock and ores.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

FOR THE WEEK ENDING DECEMBER 30, 1902.

- 717,062.—RANOE FINNER—A. A. Adams, Ebbensburg, Ariz.
- 717,063.—CONVEYER—C. J. Allen, S. F.
- 717,336.—BOTTLE HOLDER—W. E. Brown, Los Angeles, Cal.
- 717,337.—NUT THREADING MACHINE—F. P. Burnett, San Carlos, Ariz.
- 717,163.—VEHICLE COUPLING—L. H. Campbell, Portland, Or.
- 717,314.—TUBE EXPANDER—J. Carmichael, Franklin, Wash.
- 717,074.—DUMP—T. Carroll, Anaheim, Cal.
- 717,078.—MUFFLER—C. E. Christman, San Jose, Cal.
- 716,987.—EVAPORATOR—Cook & Maschke, Vancouver, Wash.
- 717,360.—SHIELDS IN CANS—W. E. Dement, Blaine, Wash.
- 717,363.—SAW—C. W. Eccleston, Centralia, Wash.
- 717,087.—GANG PLOW—L. G. Fairbank, Oakland, Cal.
- 717,089.—CELL BOX—W. H. Ferguson, San Jose, Cal.
- 717,094.—TOOTH CROWNS—B. W. Haines, S. F.
- 717,095.—DRILL—L. A. Hardison, Santa Paula, Cal.
- 717,097.—STOVE—Holmes & Hampden, S. F.
- 717,102.—SHIRT—B. Lichtig, S. F.
- 717,223.—PENCIL HOLDER—E. E. Long, Los Angeles, Cal.
- 717,233.—VAPOR BURNER—J. W. Master, San Diego, Cal.
- 717,341.—OFFICE INDICATOR—W. H. Mercer, Portland, Or.
- 717,245.—OLIVE CRUSHER—Morris & Smith, Woodland, Cal.
- 716,929.—SPEED GEAR—J. M. Ough, S. F.
- 716,930.—SPEED GEAR—J. M. Ough, S. F.
- 716,928.—SPEED GEAR—J. M. Ough, S. F.
- 717,028.—ROCK DRILL—J. H. Redfield, Spokane, Wash.
- 717,023.—ROCK DRILL—J. H. Redfield, Spokane, Wash.
- 717,120.—POULTRY ROOST—J. M. Reid, Pomeroy, Wash.
- 716,936.—STEAM TURBINE—J. Richards, S. F.
- 717,033.—SON CUTTER—C. A. Sager, Los Angeles, Cal.
- 717,230.—STOVE—F. R. Shafer, Burlington, Wash.
- 717,237.—BALLOT MARKER—T. C. Spelling, S. F.
- 717,301.—SLUICE—G. Telford, Oroville, Cal.
- 717,492.—WATER HEATER—J. F. Yoho, Seattle, Wash.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

SIDEHILL GANG PLOW.—No. 717,087. Dec. 30, 1902. L. G. Fairbank, Oakland, Cal. The object of this invention is to provide a gang plow to be used particularly upon sidehills and in which the various adjustments of the frame and plow may be effected in the simplest manner possible. It consists of a frame mounted upon front and rear wheels, said front wheels adapted alternately to serve as furrow and land wheels, connections between the axles of said wheels by which the frame may be raised and lowered, a centrally pivoted beam, standards on said beam, reversible plows turnable in a horizontal plane about said standards and the relative position of the front wheels as land or furrow wheels reversed simultaneously with the oscillation of the plow beam.

BOX TOOTH CROWNS AND ADJUSTABLE FACINGS.—No. 717,094. Dec. 30, 1902. B. W. Haines, San Francisco, Cal. This invention relates to improvements in pivot teeth and dental bridge-work. It comprises a new article of manufacture, consisting of a box or receptacle open at the top and corresponding to a tooth space and a facing secured thereto, said receptacle having means on its under side by which it may be secured to a root.

COLLAPSIBLE CELL BOXES.—No. 717,089. Dec. 30, 1902. W. H. Ferguson, San Jose, Cal. This invention relates to improvements in boxes or packages such as are designed to contain eggs, fruit or like substances; it consists in the construction of a multiple cell box or package made from a single piece of pasteboard or like material cut to the proper shape and folded to form the cells or compartments.

Latest Market Reports.

SAN FRANCISCO, Jan. 9, 1903.

METALS.

SILVER.—Per oz., Troy: London, 22½d (standard ounce, 925 fine); New York, bar silver, 48c, refined (1000 fine); San Francisco, 48c; Mexican dollars, 38 @39c San Francisco, 38½c New York.

There is practically no change in the silver situation, though it seems unlikely that it will go lower than at present.

COPPER.—New York: Standard, \$11.25; Lake, 1 to 3 casks, \$12.25; carload lots, \$11.30; Electrolytic, 1 to 3 casks, \$12.25; carload lots, \$12.00; Casting, 1 to 3 casks, \$12.15; carload lots, \$11.10. San Francisco: \$14.00. Mill copper plates, \$17.00; bars, 18@24c. London: £52 6s 3d spot per ton.

Bi-monthly statistics show a decrease of 952 tons in stocks and 627 tons in the visible supply in London. There is an upward tendency, but it is not likely that the price will go above \$12.50 at present, as the condition of the market does not justify it.

LEAD.—New York, \$4.50; Salt Lake City, \$3.50; St. Louis, \$4.00; San Francisco \$4.50, carload lots, 4½c 1000 to 4000 lbs.; pipe 5½, sheet 6, bar 5½; pig, \$4.75. London: £11 1s 3d per ton.

SPELTER.—New York, \$4.70; St. Louis, \$4.50; London, £19 17s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c. ANTIMONY.—New York, Cookson's, 9½c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 10c; 300 to 500 lbs., 11c; 100-lb. lots, 13@15c.

TIN.—New York, pig, \$27.25@27.50; San Francisco, ton lots, 29c; 500 lbs., 29c; 200 lbs., 29½c; less, 30c; bar tin, 35c. London, £124 15s spot.

PLATINUM.—San Francisco, crude, \$18.00 ½ oz.; New York, ingot, \$19.00 per Troy oz. Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, \$45.50@46.50; large lots; London, £8 15s; San Francisco, local, \$46.00 ½ flask of 7½ lbs.; Denver, \$49.50. Export, \$43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 35c; Eclipse, 37½c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30c to 34c. SOLDER.—Half-and-half, 100-lb. lots, 19c; San Francisco, Plumbers', 100-lb. lots, 16.10c.

NICKEL.—New York, 50@60c ½ lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$22.00; gray forge, \$20.15; San Francisco, bar, 3c ½ lb., 3½c in small quantities.

During 1902 San Francisco received 28,768 tons pig iron by water. Of this 26,852 tons were foreign.

STEEL.—Bessemer billets, Pittsburg, \$28.00@30.00; open hearth billets, \$30@34.00; San Francisco, bar, 7c to 12c per lb.

LIME.—Santa Cruz, \$2.25; Roche Harbor, \$2.25 per bbl.

LUMBER.—(Retail): Pine, ordinary sizes, \$20.00@22.00; extra sizes higher; redwood, \$22.00@23.00; lath, 4 feet, \$4.25 @4.50; pickets, \$19.50; shingles, \$2.35 for No. 1 and \$2.00 for No. 2; shakes, \$13.50 for split and \$14.50 for sawed; rustic, \$26.00 @32.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, \$3.30; Cut, \$3.30; 10d to 16d, Wire, \$3.35; Cut, \$3.35; 8d, Wire, \$3.40; Cut, \$3.40; 6d and 7d, Wire, \$3.50; Cut, \$3.50; 4d and 5d, Wire, \$3.60; Cut, \$3.60; 3d, Wire, \$3.75; Cut, \$3.75; 2d, Wire, \$4.00; Cut, \$4.00. Special rates for carload lots.

GENERAL SUPPLIES.

POWDER.—F. O. B. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2 per keg.

CAPS.—3x, \$5.50 per 1000; 4x, \$6.50; 5x, \$8; Lion, \$9, in lots not less than 1000.

FUSE.—Triple tape, \$3.60 per 1000 feet; double tape, \$3.00; single tape, \$2.65; Hemp, \$2.10; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10½c ½ set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 25@26c ½ lb.; carloads, 24@24½c; in 10-lb. tins, 35c; sulphuric acid, in carboys, 66½ B, 2c ½ lb.; soda ash, \$2.00 ½ 100 lbs.; hyposulphite of soda, 2½@3c ½ lb.; blue vitriol, 5½@6½c ½ lb.; borax, concentrated, 7@8c ½ lb.; chlorate of potash, 12@13c; roll sulphur, 4@6c; ground sulphur, 4@6c; flour sulphur, French, 2@3c; alum, \$2.00@2.25; California refined, 2@2½c; nitric acid, in carboys, 8c ½ lb.; caustic soda, in drums, 3@4c ½ lb.; Cal. s. soda, bbls., \$1.25 @1.50 ½ 100 lbs.; sks, \$1.05; chloride of lime, spot, \$3.00@4.00; nitrate of potash, in bbls, 8c; caustic potash, 10c in 40-lb. tins; sulphide of iron, 9c ½ lb.; copper sulphate, 5@7c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.50; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lots, Eastern and foreign: Wallsend, \$6.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8; Cumberland, \$12; Cannel, \$9.00; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13 in sacks; Sunnyside, \$8.50, long ton.

During 1902 San Francisco received coal as follows:

From—	Tons.
British Columbia.....	591,732
Australia.....	197,328
England and Wales.....	95,621
Scotland.....	3,000
Eastern States (Cumberland and anthracite).....	24,133
Mt. Diablo, Cal., Coos Bay, Or., and Tesla, Cal.....	111,209
Japan, and Rocky Mountains, by rail.....	47,380
Seattle, Wash.....	165,237
Tacoma, Wash.....	209,358

During 1902 San Francisco received 64,916 tons coke by water, as against 34,533 tons in 1901. Of this, about 50% came from Great Britain, 18,000 tons from Belgium and Germany, the remainder from Australia and British Columbia.

OILS.—Lined, boiled, bbl., 54c; ca., 59c; raw, bbl., 52c; ca., 57c; lots of 5 bbls., 1c less; Lucol oil, boiled, bbl., 48c; ca., 53c; raw, bbl., 46c; ca., 51c. Kerosene—Pearl, per gal., 22½c; Astral, 22½c; Star, 22½c; Extra Star, 22½c; Eocene, 23½c; Elaine, 23½c; Water White, in bulk, 16c; Mineral Seal, iron bbls, 18c; wooden bbls., 20c; ca., 24c; Mineral Sperm, ca., 26½c; Deodorized Stove Gasoline, bulk, 17c; do., ca., 23c; 86° Gasoline, bulk, 21c; do., ca., 27½c; 63° Naphtha or Benzine, deodorized, in bulk, per gal., 16c; do., in ca., 22½c; Lard Oil, No. 1 bbl., 95c; ca., \$1.00; Neatfoot oil, bbl., 70c; ca., 75c; No. 1 bbl., 55@57½c; ca., 57½@60c; Sperm, crude, 50@60c; Natural White, 65c; Bleached do, 70c; Whale Oil, ca., 50@55c.

California's 1902 oil production was 13,000,000 barrels, equal to 3,000,000 tons coal. Kern county produced about 18,000 barrels daily.

RED LEAD.—One ton and over at one purchase, per lb., 6c; 500 lbs. and less than 1 ton, per lb., 6½c; less than 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8 @9c per lb.

BONE ASH.—Extra No. 1, 5@6c per lb. No. 1, 4@5c.

BORAX.—Concentrated, 7@9c per lb.; powdered, 9@12c; fused, 25@30c.

BISMUTH.—Subnitrate, per lb., \$1.60.

BONE ASH.—4c ½ lb.

BORAX.—Crystal, 7c; calcined, 25c.

CHROMIUM.—(90% and over) per lb., \$1.25.

COPPER.—Sulphate, 5@7c.

MANGANESE.—(90% and over) ½ lb., \$1.25.

MERCURY.—Bichloride, ½ lb., 90c.

MOLYBDENUM.—25c ½ gramme; 1000 grammes=2½ lbs.

PHOSPHORUS.—(American) ½ lb., \$1.00.

SILVER.—Chloride, ½ oz., 75c; nitrate, 55c.

SODIUM.—Metal, ½ lb., \$1.25.

URANIUM.—Oxide, ½ lb., \$3.50.

ZINC.—Metallic, chemically pure, ½ lb., 50c; dust, ½ lb., 10c; sulphate, ½ lb., 04c.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

At What Depth Do Wet Mines Become Dry?

The question that many mine managers would like to solve is, At what depth may they expect water in the mine workings to cease to give trouble? That this important question can be determined without actual test by sinking until the desired condition is found does not appear possible. A careful inquiry into the history of deep mines throughout the world shows no uniformity in either conditions nor the quantity of water encountered in depth. It is true that there are districts where the upper levels of mines are far more wet than the lower levels, but the reverse is as often the case. The Kennedy mine, near Jackson, Amador Co., Cal., which has the deepest vertical shaft in California, and in fact all of the mines along that portion of the gold belt of California whose workings extend below 1500 feet from the surface are comparatively dry in the lower levels, although there are large amounts of water in most of them above the 1000-foot level. All of the principal shafts of Amador county are not only far below the drainage level of the neighborhood, but many hundred feet below sea level.

The shaft of the Silver Islet mine, sunken within a coffer dam on a small rock in northern Lake Superior, developed a comparatively dry mine, and yet the levels extended hundreds of feet beneath the lake. The mines of Leadville are very wet, and will always be so unless drained by tunnels. The geological conditions are such that there is little hope of finding a drier zone at moderately great depth.

The Ontario mine, Park City, Utah, has always been a very wet mine even to its lowest levels, below 2000 feet from the surface. The mines of the Comstock lode at Virginia City, Nevada, are very wet, with no indication of diminishing flow even in the deepest workings—over 3300 feet.

The mines of Pioche, Nevada, were dry to about

1200 feet from the surface, when large volumes of water were encountered which practically resulted in closing the mines. The deep copper mines of the Lake Superior region—one vertical shaft, the Red Jacket of the Calumet & Hecla Co., being nearly 5000 feet deep—and the deep inclined and vertical shafts of the majority of mines of the Witwatersrand, in South Africa, are not to be placed in the category of very wet mines. Some of those on Lake Superior are even dusty in the lowest levels.

In fact, among deep mines are found those which are extremely wet and those which are practically dry in their deepest portions; and while undoubtedly there is a point below the earth's surface where the interior heat either dries up all the moisture or turns it to steam, it is evident that this point has not as yet been reached nor even approached in

mine workings. The character of the rocks traversed by veins and the number and condition of the fissures and dikes other than veins that intersect it have an important influence on the flow of underground waters.

A mine after long and continuous drainage becomes comparatively dry perhaps; but let operations cease, and permit the water to rise to its natural drainage level, and then attempt to unwater the workings, and it will be found that the quantity of coming water to be handled vastly exceeds the amount flowing in normally after not only the mine workings, but the surrounding country, have been drained.

Mining in Honduras.

Honduras, Central America, is possessed of great undeveloped mineral resources, but the inaccessibility of the mining regions has greatly retarded the development of that country. There are few wagon roads in Honduras. All mining and milling machinery is packed on animals, or carried by men. The greater number and more valuable mines, so far as known, are in the interior of the country, from 100 to 400 miles distant from seaports. The mines are of various kinds, though chiefly gold, silver and copper. The most noted gold mining section is in the Department of Olancho. In that department are many gold-bearing veins, few of which are developed. Extensive placers also are found in Olancho, but these have been worked for many years. There are large beds of conglomerate which may prove on investigation to be gold-bearing, as they are in a gold gravel country. In many respects these conglomerates resemble those of the Witwatersrand. They are intercalated in red sandstones and are intersected by dikes of diabase or other basic rock. These are well exposed in the region of the Guayape and Parnal rivers, but are without development.

ARIZONA should have statehood in 1903. Precedent, policy, business, good faith, all favor the creation of that commonwealth into the forty-sixth State of the Union. The Territory has the resources, population and prosperity that entitle it to statehood, and its advance in all that goes to make an American State would be the quicker therefor.

IT is hardly necessary to remind the several Legislatures of the mining States of the desirability of making proper appropriations for suitable representation of the mining industry at the coming St. Louis Exposition. This is an age of advertising, and that exhibition affords a fine chance for good advertising that will aid in the mineral development of the country. It will be money well spent for every mining commonwealth to make suitable appropriation for good display at St. Louis in 1904.

THE general advance in costs of everything purchasable is as yet not manifest in any great increase in the cost of expert service, though it is inevitable. In this regard may be noted in a general way that the price of personal service in the mining and engineering world is not at present commensurate with the quality of service required. While there has been a constant advance in the requisite technical skill and attainments of engineers, there has not been a corresponding advance in the salary paid. Particularly is this noticeable in the case of the electrical engineer, who is often expected to supply skilled service at very ordinary wages. In this, as in all other cases, "the laborer is worthy of his hire," and a position demanding the services of a trained and practiced man, in a place of importance, should have sufficient salary accompanying it. The engineering profession, whether mining, electrical, civil or mechanical, is entitled to such professional recognition.

Mining Stock Contracts.

The Supreme Court of the United States has decided in the case of Otis & Co., plaintiffs in error, vs. E. A. Parker, defendant in error, that section 26 of article IV of the constitution of the State of California is not unconstitutional. This section is in reference to dealing in lotteries and stock gambling on margins, and declares that the buying of stocks on margins in stock boards, exchanges or markets, or a contract for stocks to be delivered at some future time is illegal and all such contracts shall be void. All contracts for the sale of shares of the capital stock of any corporation or association on margin, or to be delivered at a future day, shall be void, and the money paid on such contracts may be recovered by the party paying it by suit in any court of competent jurisdiction. This law is aimed directly at the stock brokerage business, as carried on in the exchanges of San Francisco, but it is an open question to what extent it may affect dealings between the directors of mining companies and subscribers to the stock of such companies. A great many mining companies in California are organized on the progressive plan, wherein those desiring to become interested in the enterprise agree to pay stated sums at regular intervals—usually monthly—until the entire sum agreed upon in the contract shall have been paid, when the secretary of the company issues a certificate entitling the subscriber to a given number of shares of stock in the corporation. Previous to this time the subscriber holds only a certificate, contract or agreement, which sets forth the terms under which the subscriber shall be entitled to shares in the company, but he is not in the meantime an actual stockholder in the company. From the language of the statute it may readily be seen that this method of disposing of mining shares may come directly under this decision of the supreme court.

THE returns for 1902 are nearly all in for the mining States. The result is moderately satisfactory. Among the most noticeable features is that the base of the metal mining industry is what is called the "low-grade proposition." Few indeed, and noticeable because of their fewness, are the "high-grade propositions." It is the many thousands of low-grade producers that make up the bulky figures for 1902. It is in them that lies the greater profit. And it is mining and scientific progress that has made such profit possible. It is only by close economy and skillful operation that the most of the low-grade producers can afford employment or reason for continuous operation. Upon these rests the prosperity of the mining industry, a base that is dependent in its turn in a larger degree every year upon the knowledge and ability of the miner and metallurgist. What is required of the mining engineer who is placed in charge of most large properties in these days is not that he shall know how to make a rich mine pay, but how to make a low-grade mine pay. He must be familiar with every device, mechanical and otherwise, that will cheapen cost, and the men most in demand are those who have demonstrated their ability to engineer low-grade properties at a profit. The equipment of new property is no longer a haphazard matter. It is not hastily planned, but all the details are carefully studied out and comparisons made before final decision is arrived at. The object is to reduce labor, and labor means expense. To increase capacity during a stated time (and time is money), and this whether in the mine, the mill, cyanide works or smelter; mechanical underground haulage; thoroughly equipped shafts; complete and well-arranged metallurgical works, all tend to reduce expense, and are features of well-equipped and properly managed mining enterprises.

THE industrial growth of this country is strikingly exemplified in the one case of electrical progress. In the single item of electrical construction and repairs, which is but a small detail of the amount represented, it is of note that in 1850 there were two establishments in the United States for supplying electric appliances, with a total capital of \$3750, and a product valued at \$5100. In 1902 there were 1938 such establishments, with a capital of \$95,684,376, and an output valued at \$116,984,743.

Advancement in Cyaniding.

The cyanide process was first successfully introduced in America about 1890, though it was known as early as 1806 that gold was soluble in a solution of potassium cyanide. L. Elsner in 1844 published the results of investigations made by him on the reactions of various metals in an aqueous solution of potassium cyanide. From a comparatively small beginning and a stage of great uncertainty the process has developed into commercial success, and plants are now in operation in America having capacities reaching to 1200 tons daily. While it is still true that the adaptability of any untried ore to the process is an experiment, the methods of determining whether any particular ore is amenable to cyanide treatment have been reduced to an exact science, and there are now few gold ores that cannot be made to yield up a large percentage of their values, though this may involve preliminary preparation in the way of crushing, grinding and sometimes roasting. The process, as practiced to-day, has been evolved from a long series of experiments, mostly made by men entirely competent to make them, and it is a story of hope, failure and final success. These men have given freely of the knowledge thus gained, publishing not only the results of their experiments, but the methods pursued, in detail. It is not the outcome of one man's knowledge or effort, but that of all engaged in the investigation and practice of cyaniding gold ores. Very material changes have been made in the mechanics of the process as well as in its chemistry, and while the process of to-day seems to have approached perfection, there is no doubt that the future will see its broader and still less expensive application.

UNDER the agreement between the leading mining men of the Witwatersrand and Colonial Secretary Chamberlain, it is understood that the Transvaal mines will guarantee the interest on \$300,000,000, half of which is to be devoted to public works, while the other half will constitute a war contribution to the government. This is considered in London an equitable adjustment of the matter, and now that uncertainty has been removed renewed activity in the mines of the Rand may be looked for. The labor question has become a serious one, however, as the mines cannot work at a profit without cheap labor. The bringing of large numbers of natives from Uganda, on the east coast, has been considered, but owing to the difficulties experienced and anticipated in this direction it is now thought the Imperial Government will consent to the importation of Chinese laborers for the mines.

ADVICES from various points indicate that smelting companies are making determined effort to break up the petty swindles occasionally perpetrated upon them. At Northport, Wash., the smelter company has been the victim of a gang of thieves who have stolen matte worth from \$3.50 to \$6 per pound, one of them, who was arrested, having about 200 pounds of the stuff in his possession. This was just an ordinary case of stealing. At Val Verde, Arizona, the company has had difficulty with some of its customers, who are accused of having scientifically salted their ore, in raising the value of samples of a carload of ore to the amount of nearly \$2000. But the salting was not done scientifically enough, as the smelter's employes, by accurate processes of sampling and assaying, were able to detect the over-values.

SECRETARY of the Interior Hitchcock has a bill before Congress to amend the present land laws that is of sufficient merit to warrant endorsement. It is in the interest of the forests of this west half of America, and if it passes will place all public forest lands under a proper system of protection from fire or destructive lumbering. The proposed repeal of the timber and stone land law is a little too radical a remedy for timber frauds and despoilation, but the bill fostered and presented by the Secretary of the Interior will afford adequate protection to the mining and manufacturing interests, and also stop speculation in forest reserve scrip. The bill partakes of a form of remedial legislation that deserves endorsement.

CONCENTRATES.

It was long since determined that battery screens inclined outward at the top facilitated discharge.

ECLOGITE is a fine-grained granular rock, consisting of red garnet in a base of grass-green smaragdite (a thin foliated variety of amphibole).

"OIL OF GOLD" exists—in the brains of fanciful men, but nowhere else. "Oil of gold" in its nascent state is in close connection with the tangible effect of a chimera revolving in a vacuum.

ANY coining U. S. mint will give gold coin for gold bullion, the only charge being for the necessary copper to make the 900 fine alloy, or for parting should the bullion be below 900 fine.

AIR entering the cylinders of an air compressor should be as cool and pure as possible, as the lower the temperature of the inlet air the greater the efficiency, and the warmer the air the greater the loss.

THE fact that two or more rock quarries are located in the same district does not signify that the rock taken from each has equal value as a building or ornamental stone. Often there is a wide difference in quality.

IT has been claimed that petroleum has been successfully solidified for ocean transmission, and E. J. Hoffman of Chicago is said to have made satisfactory transatlantic shipment of solidified oil, but the accounts seem to lack verification.

PROSPECTORS will probably get better average results in searching for veins or deposits containing gold, silver, lead, copper, zinc and tin than in looking for rare minerals which usually have an uncertain and frequently changing valuation.

IN the case of Shattuck vs. Costello, 68 Pac. Rep., Arizona, 529, it was decided that other mining claims may properly be used in a mining location to designate the boundaries of the claim, as it is a sufficient reference to natural objects and permanent monuments to comply with the statute.

GARNETS of brownish color and resinous luster are sometimes mistaken for zinc blende. The great difference in hardness—garnet 6.5 to 7.5 and zinc blende 3.5 to 4, and in specific gravity, garnet 3.1 to 4.3 and zinc blende 3.9 to 4.2—should serve at once to distinguish them apart. A drop of nitric acid on pulverized zinc blende will evolve fumes of sulphuretted hydrogen. Garnet fuses easily before the blowpipe, while zinc blende is difficultly fusible.

THE oxidized zone in veins and ore deposits is produced by the alteration of the original deposit through atmospheric agencies and drainage. In some mines the oxidized zone ends abruptly, the ore changing within a foot from an oxidized to a sulphide or normal condition. In many others the ores change by imperceptible gradation from the oxidized to the sulphide condition. This latter condition is not uncommon where the sulphides are encountered before the water level is reached.

IN the case of the Alaska United G. M. Co. vs. Muset, 114 Fed. Rep., U. S., 66, it was decided that where a corporation owning two mining plants has a general superintendent, with a general oversight over both plants, and a foreman of each mine, who employs and discharges the men, and directs and controls the entire operations of his mine and of the various gangs of men there employed, such foreman is a vice-principal, for whose acts and negligence in the conduct of such mine the owner is responsible.

IN extracting copper from ore assaying 2.5% Cu it is common practice to mix about 200 pounds of salt with 2000 pounds of ore, that quantity being about 107 pounds in excess of what is theoretically required by the copper. A ton of ore assaying 25% Zn would require theoretically about 900 pounds pure salt, or 1000 pounds if the same excess were used as in copper extraction, but in all likelihood an excess would be needed, as a considerable portion of the lead would likewise be converted into chloride, soluble in hot water, insoluble in cold.

THE best height of discharge, the best screen to use, the proper amount of water in the battery, the height of drop of stamps, and grade of plates are all things that must be determined by practical experiment. The motto "get all the capacity possible" is a good one when coupled with "get all the gold possible." The exact point where these two should meet must be determined by the good sense of the mill man or the superintendent. When it costs 10 cents per ton more to save an additional 5 cents per ton from the tailings the point of greatest economy has been passed.

THE latest method of hardening the face of armor plate is by heating the face with electrical currents by means of large carbon anodes instead of applying the heat in a furnace. It has been found that during the

electrical treatment a portion of the carbon of the anodes enters into the composition of the steel, producing great hardness of that metal. The depth to which the hardening proceeds is regulated by the length of time during which the treatment is applied. It is claimed to be superior to the Harvey system or that of Krupp. By the latter process plates require fifteen to twenty days treatment. With the electrical method the desired result is accomplished in five hours.

A GERMAN SCIENTIST, H. Jansen, N. W. 7, Dorotheen Str. 49, Berlin, Germany, is now essaying the very task suggested by our Mexican correspondent, viz., a technolexicon; a dictionary of all technical terms used by French, German, English or American engineers, so that the compilation shall contain equivalent words and expressions in all three languages. The general idea is commendable, but two obstacles readily suggest themselves: First, To what limits shall go the definition of the word "technical?" second, No matter how circumscribed, these limits may be the manifest magnitude of the task and the apparent impossibility of accurate progress except by a systematized and extensive collaboration.

MONAZITE is an anhydrous phosphate of cerium, lanthanum and didymium. In color it is light yellow, honey yellow, reddish, brownish or greenish yellow, with a resinous to vitreous luster, and is translucent to sub-transparent. It is brittle and is 5 to 5.5 in hardness. It is only obtained by sluicing the sands and gravels and never by rock mining, as the mineral occurs usually in small disseminated grains, though crystals of monazite have been found in a dike at Mars Hill, Madison county, N. C., which were 1½ inches in length. These occur in a pegmatite dike. Gold frequently is found in regions where monazite occurs. It is then recovered as a by-product in placer mining for gold. Monazite has not been reported in California as yet. It is usually found in regions of granite and its gneiss and schist.

THE fact that the ore shipped from the district shows less value per ton than it did five years ago does not necessarily imply decreasing values. It may mean, more likely, that increased treatment charges and decreased transportation charges enable ore to be mined and shipped that formerly would not pay for handling. It is not uncommon for mining districts now to ship annually thousands of tons of ore that ten or even five years ago would have been left in place as worthless. The increased tonnage, of course, decreases the average, and superficial figures may make it seem that ore values are decreasing; but it may be that the fact is where 10,000 tons of \$50 ore were shipped that now 200,000 tons of \$30 ore go out, the aggregate being \$100,000 more for the district, even though the average per ton value might seem much less.

IN the Knox system of blasting employed in quarrying, reference to which was made herein in the issue of Dec. 27, 1902, it is sometimes considered necessary to cut at either side of the holes drilled V-shaped notches to render the rising of the rock more certain in the desired direction and also to expedite the process. At the Raymond granite quarry, Madera county, Cal., two holes drilled 8 inches apart, but not having the V-notches cut in the line of fracture, have been known to split the granite in a true vertical plane for a distance of more than 60 feet and to a depth of 20 to 25 feet to the next underlying joint plane. The block of rock between the joints in this quarry are of great size; one measuring 360 feet in length, from 4 to 6 feet high at the ends and 25 feet thick in the middle, and exposed on the surface for a width of over 60 feet, all without a single crack or flaw. It is in rock of this character that the Knox system works to the best advantage.

THE capacity of a stamp battery depends upon a number of factors, and no constant can be given. Things which affect capacity are weight of stamps, height of drop, number of drops per minute, kind of screen employed and superficial actual space of discharge, height of discharge, and quantity of water used in the battery. The width and length of the interior of the mortar also has an important bearing on this matter. In addition to this no fixed set of conditions is ever maintained for any considerable period, as the wearing down of the die increases the height of discharge, which is again adjusted by inserting a lower chuck block. The weight of the stamp is variable by reason of wearing down of the shoe, the height of drop constantly increasing, unless the taps be reset to equalize it. Besides these few things the character of the ore is a very important factor in discharge. A flinty, flaky ore will not discharge through a round aperture as rapidly as through a slotted screen. A hard but easily crushed brittle ore will discharge more rapidly than a soft, spongy ore that will clog up the screens, etc.

CHROMITE, or chromic iron, occurs in a number of States, notably Pennsylvania, Maryland, North Carolina and California. It occurs only in the peridotites and allied igneous basic magnesium rocks or in serpentine which results from an alteration of these rocks. It always occurs as pockets or hunches of irregular extent, often the solid ore graduating by almost insensible degrees into the surrounding rock mass. Where chromite is mined there are often large quantities of the low-grade ores left standing in the mine or thrown out on

the dumps. Ordinarily, on exposure this material disintegrates rapidly and a high-grade product can be obtained by simply sluicing, the gangue being washed away, the chromite filling the riffles. The chief use of chromite is in the manufacture of chromate and bichromate of potash. It is also employed in the manufacture of hard, tough steel, particularly shoes and dies in rock crushing machines and stamp mills. The standard ore must contain 50% chromium oxide, and must be low in silica. It is sometimes used in lining furnaces for smelting copper and other ores, for which purpose it is superior. Bricks for this purpose are made of a mixture of chromite, bauxite and milk of lime. The mineral is well adapted to this use, as it is infusible, does not become friable when heated and cooled, and is not attacked by the acids or gases arising from smelting of ores.

CRYOLITE is fluoride of sodium and aluminum, and in appearance resembles ice. It occurs in great snow-white masses which are partially transparent. Its hardness is 2.5 and it has three cleavages. It is obtained exclusively from Ivigtok, in Greenland, on the Arksuk Fjord. The cryolite occurs as a large bed in a granitic vein in gray gneiss. It is limited to the granite, the richer portion being about 500 by 1000 feet in area. Associated with the cryolite in small amounts are quartz, beautiful crystals of iron carbonate (siderite) and galena, with smaller quantities of sphalerite, pyrite, chalcocopyrite, and wolframite. Surrounding the richer portion of the cryolite mass is a zone of quartz, feldspar and a variety of muscovite mica. Besides these there are fluorite, cassiterite (tin oxide) and arsenopyrite. The line of demarcation between the cryolite and the outer zone is clearly defined, but the outer zone passes gradually into the granitic mass. The cryolite is mined in a cut 600 feet long, 200 feet wide and 100 feet deep. Ships' cargoes have been obtained containing 99.5% pure cryolite. It is employed chiefly in the manufacture of sodium and aluminum salts, and more sparingly in making hydrofluoric acid. It is also used to a limited extent in the manufacture of an opalescent glass resembling porcelain. Cryolite has been discovered in small quantity in El Paso county, Colo., at the southern base of Pike's Peak, and in the Yellowstone National Park.

URANIUM and vanadium are in some demand, chiefly for experimental purposes. They are also employed in limited amount in steel manufacture. The chief sources of uranium are uraninite, gummite and carnotite, the latter containing considerable vanadium. The principal sources of uraninite are at the Wood, Black Hawk and Kirk mines, near Central City, Gilpin county, Colo., and on Dolores river, 80 miles west of Dolores, Montezuma county, Colo. It has been found at Paradox valley in Montrose county, Colo. In South Dakota it is found in small green scales incrusting the siliceous ores of the Ross-Hannibal mines in Ruby Basin, and on a porphyry mountain west of Terry's Peak, in Lawrence county. Carnotite is found on La Salle creek, southwest of Paradox, Colo. The mineral contains 47.654% uranium oxide, and 15% to 18% vanadium oxide. Vanadinite is lead vanadate, and is found in quantity in mines of Arizona and New Mexico. It was particularly abundant at the Vulture and Phoenix mines in Maricopa county and at the Mammoth mine, Pinal county, Arizona, and at Toke valley, Sierra county, New Mexico. Uranium and vanadium are employed in making ferro-alloys of these metals. They increase the tensile strength and toughness of steel to a remarkable degree. Thus far, however, it is only the product of laboratory experiment, no steel having been made with these metals in commercial quantities. Colorado is the principal producer of these minerals.

THE principal source of molybdenum is molybdenite (MoS₂). It is usually found in foliated masses or in scales with perfect basal cleavage and bright metallic luster. When crystallized it occurs in short or flat hexagonal prisms. It is very soft, 1 to 1.5 in the scale of hardness, of pure lead gray color. Molybdenite and graphite are often mistaken one for the other, but molybdenite is more metallic looking and has a bluish-gray cast. Its streak on paper also differs from that of graphite, the latter making a dull black streak, the former bluish black. Before the blowpipe, the best test, molybdenite gives forth sulphur fumes (sulphur dioxide), while graphite remains unchanged, giving no fumes when heated. Molybdenite occurs in scales in granite, gneiss, syenite, granular limestone and in quartz veins. In California it occurs in numerous localities, one important one being in Mono county, 12 miles northwest of Bridgeport. At this place it occurs in a large vein of vitreous quartz. Molybdenite is also reported in Alamo mountain in Ventura county, Cal. It is found in a vein 8 to 15 feet wide. Other occurrences are reported from Washington, Utah, Arizona, New Mexico, Montana and Alaska. The principal uses of molybdenum in recent years has been in the manufacture of certain chemical reagents, especially ammonium molybdate, used in determination of phosphoric acid. Also in the preparation of "blue carmine" for coloring porcelain. It is also employed in steel manufacture. Molybdenum is sold as the metal and as a nickel-molybdenum alloy. The quotations on molybdenite are variable, from 10 cents to \$1.10 per pound. To be marketable the ore must contain over 45% molybdenum and be free from copper. The amount used is limited, and the market could easily be oversupplied, with a consequent reduction in price.

The Cripple Creek, Colo., Drainage Tunnel.

Written for the MINING AND SCIENTIFIC PRESS by
W. B. WILSON, C. E., Colorado Springs, Colo.

The difficulties connected with handling the water in the deeper mines of Cripple Creek district have to some extent been exaggerated, and by constant iteration and reiteration in the newspapers of varying ideas on the subject, mostly by laymen totally unfamiliar with handling water, it has begun to assume the appearance of a very large bugaboo. For the benefit of your readers who are not familiar with the Cripple Creek district, it may be roughly described as located in an area of low, rolling hills, which lie between Pike's Peak and the Arkansas river, the extent of the district being approximately 2½ by 3 miles. For some years after mining operations began, the camp was generally considered to be a dry one, most of the mines then operating being located rather towards the tops of the hills. The first water encountered was in a short tunnel on the Blue Bell property in Squaw gulch, opposite the Mary McKinnie mine, and at an elevation of about 9500 feet, and as the water in this case came out with considerable force, showing a head of water back of it, the existing ground water level was probably 50 or 60 feet higher. As the various shafts over the western half of the district were gradually sunk to this elevation, it was found that each in their turn began to encounter a considerable quantity of water as soon as they commenced opening up their water levels. Fortunately, at about the same time, a tunnel formerly known as the Moffat, which was being driven into Gold Hill, got into water and helped that much towards draining the ground, some 2500 to 3000 gallons per minute flowing from it for some time.

Following this tunnel, another known as the Standard, at an elevation of 9031 feet, near the lower end of Beacon Hill, which had been extended into the phonolitic core of the hill, also began draining the water, and from late in 1898 until May, 1901, a very large stream of water—as much as from 3000 to 5000 gallons per minute—poured from this opening. The drainage effected by this tunnel was immediately noticeable over the greater part of the district, not only in the pumping shafts, but by the drying up of the Moffat tunnel shortly after the Standard began flowing.

There is nothing unusual or different in the water occurrence from that in other camps. The quantity to be pumped does not approach in amount that encountered in Leadville, and with the important difference that in the case of Cripple Creek, located in a comparatively arid region, with a total annual precipitation of only about 6 inches, the addition by saturation to the underground water is comparatively trifling. In Leadville, situated in the heart of the main range, where the snowfall is heavy in winter, and with hard summer rains, a constant addition is being made to the underground flow, and a cessation of pumping by the mines would mean a return to the original elevation at which water was encountered. In Cripple Creek the drainage of a vertical foot of water means just that much less to be pumped, as the annual increment from surface water is practically nil.

It has unfortunately been the case that during the drainage of the deeper pumping shafts in the western half of the district—where, on account of more or less openness and porosity in the north and south veins and connecting cross fractures, the elevation of the water has been practically the same in all of them—that when one got below the level of the other with its pump station, and began opening up the ground, it immediately had to pump more than its share, with the result that it was found to be too big a contract for any one mine to carry through. If it had been the case, as in Leadville, of a great many shafts all pumping at the water at the same time, and the cost distributed among many, we would have heard very little from any of the mines on the subject. In the case of the Elkton, which made probably the most determined and gallant fight of all, it was principally a case of biting off more than they could masticate that caused most of their trouble. The shaft had been sunk from 600 to 800 feet, where the pump station was cut out and large pumps installed, and later work began in opening up the veins in the 700 and 800 levels simultaneously. A sudden influx of a great volume of water from a cavernous opening in the south level on the 700-foot drowned the pumps at No. 8; the subsequent recovery of these by means of sinking pumps being a slow and costly process, it was only accomplished by first fighting the water back into the seventh level and bulkheading it, and by putting in another bulkhead in No. 8, when that level was finally recovered. These cement bulkheads served their purpose admirably, and permitted the drawing off of the water in such quantities as could be readily handled by the station pumps; but, even then, handling as they did some 2000 gallons per minute for many months, the cost was prohibitive in the extraction of medium and low-grade ore at any profit.

The steps which have been taken by the Mary Mc-

Kinnie, El Paso and Elkton mines toward the driving of a comparatively short drain tunnel to intersect the El Paso shaft at 585 feet depth, or 230 feet below the present water level in the deep shafts of the district, are steps in the right direction; but the matter should not be allowed to rest with the comparatively small amount of drainage which will be effected by this tunnel. It will be well to hear in mind that even when the tunnel has been driven into the water-saturated area and drainage begun, there will be a long period of waiting for the water to subside, or until the water will be drawn off to the tunnel level. Residents of the district will remember that, although the Standard tunnel begun draining in 1893, it was not until 1901, during which period the Elkton, Mary McKinnie, Doctor-Jack Pot and, for a considerable part of the time, the Moon-Anchor, were steadily pumping, that complete drainage was finally effected. The recession of the water, as noted in the Moon-Anchor during the time when pumping was being carried on most vigorously, and the Standard at the same time discharging its largest volume of water, was only about 1 inch per day; so that it is evident that, even after this proposed tunnel begins draining the water, a considerable period of time must necessarily elapse before some of the deeper mines will be able to resume sinking and opening up their working levels to the depth which will finally be drained by this tunnel.

Knowing that drainage at the best is extremely slow, it would be wise on the part of those providing funds for the completion of the first tunnel to at the same time make an effort to raise an additional amount for the purpose of beginning another and longer one to drain to a greater depth of from, say, 300 to 500 feet. Then, while the first was performing its duty, and during the waiting period, the second could be completed and share with the first one in giving more rapid action on drainage, so that by the time the ground above the first was worked out a greater depth free of water would be awaiting them.

It has been urged as a reason against the driving of a tunnel at great depth that it is possible that the water zone may not be of great thickness, and that there would be a probability of the tunnel penetrating dry ground, and, consequently, being of no value. A great many arguments can be made, both pro and con, on this subject, various writers on the genesis of ore deposits and the circulation of underground waters having widely diverging opinions, quite a number leaning towards a belief in a comparatively limited thickness in the zone affected by circulating waters, while many of our latest and best American writers give by far the greatest burden of proof in favor of very deep circulation in most cases. The mineralization in Cripple Creek has so manifestly been aqueous and caused by circulating ground water (or solutions) that there is no room for argument as to its origin; the question as to how deep it will go is mere theorizing. It is not meant to be implied that the now existing waters caused the deposition of minerals, or that a diminution of the quantity of water would mean a lessening of the mineralization, but it is an indication of the permeability of the veins and dikes to great depth; thus, 800 feet in depth at the Elkton shaft would correspond to 1900 feet at the Isabella, or about the depth that those arguing against deep circulation assert is the limit beyond which it can not exist.

This much has been demonstrated, that in many of the deeper mines, as the Portland, Vindicator, Ajax, Last Dollar, Golden Cycle, Gold Coin, Strong, Blue Bird, Wild Horse, Elkton, Mary McKinnie, El Paso, Gold King and others, there is as yet no sign of impoverishment in the veins; but, on the contrary, not only has the grade of the ore held its own, but there has been a very marked increase in the extent of the mineralization of the veins and dikes at depth, as compared with nearer the surface, the apparent lower average grade of the ore now shipped from the district being caused by increased tonnage from the mines and less discrimination in assorting.

A very good argument against one well-known writer's views on the subject of deep circulation is to be found in Cripple Creek. He strongly questions the circulation of water at all at great depth, and, among other arguments against the permeability of rocks, cites, as an instance, "that standing water in abandoned shafts is strong evidence of the impenetrability of rocks." The very fact that abandoned shafts are so generally filled by surface water also establishes that, while it ran in there, it carried with it a certain amount of clay and silt, which would naturally, after repeated fillings, close up small crevices and capillary openings and would have a tendency to make it watertight. It does not seem like a good argument for his side of the question. It was frequently noted that when it was necessary to close the bulkheads in the Elkton mine that the pressure gauges affixed thereto indicated very shortly after they were closed the exact height, within a few inches, of the standing water in the district and that the closing of these bulkheads was immediately noticeable in the Doctor-Jack Pot and Mary McKinnie, 1 mile distant, by an increase in their water flow. It is difficult to believe that, after the water is drained from a level in one of those mines, it could have been so wet, as they very often seem more than usually tight and hard and lacking in vugs and

cracks; yet when they were on the water level the water seemed to come out as if squeezed from a sponge through every pore, and from the natural cleavages in the basalt and phonolite as if from a syringe, and yet there was no opening that was visible to the naked eye.

Although it is more than likely that at greater depth the volume of water may diminish on account of the cessation of some of the shallower and lower fissures and the closing by sedimentation and pressure of capillary openings, causing a slower flow of the water into the mine workings, so far there has been no evidence whatever of decrease in the volume of water, nor in the area of the brecciated mass, in which the greater number of the producing mines are located. It is probable, however, that at great depth the water will percolate so slowly it will not be difficult to dispose of it by pumping when the mines get below that portion to be drained by a tunnel or tunnels.

The water question, although a grave one as a matter of course, will not be looked on as so serious after the first drain tunnel has been driven, and it is a comparatively small affair; but another should not be started or driven on too small a scale. The larger and longer the opening the greater the drainage, on the same principle that an oil well will flow more oil after it has been torpedooed than it did before, and the cost of excavating a larger opening is more than made up by the greater facility offered for faster work. The Newhouse tunnel, at Idaho Springs, some 2½ miles in length, was driven proportionately much cheaper than other tunnels in the State of smaller dimensions, plenty of room for the drill men and the handling of the broken rock being furnished in the liberal opening of 12x12 feet in the clear, the cost per foot, according to the superintendent's statement to the writer, being only a few cents over \$19.

When the immensity of the issue at stake is taken into consideration, when one stops to think of the greatness of Cripple Creek's contribution to the world's visible gold supply, some \$120,000,000 in gold already produced from an average depth in the larger mines of less than 700 feet, with every promise that a still greater amount will be produced by an added depth, it seems strange to the outside world—to those holding stock in some of the deeper mines, but with no say as to what shall be done with their property—that the directors and managers of these mines have been so dilatory in taking steps to inaugurate a system of drainage which will solve the problem for all time. The pumping system has been tried and found wanting; the enormous cost accompanying it has been found prohibitive in the production of medium and low-grade ores at a profit, and mine owners now generally recognize that tunneling is the easiest and best solution, the more especially as very great depth can be gained in a comparatively short distance.

During the time when the Elkton Company were having their hardest fight with the water, they engaged a competent engineer to make a complete report for them as to the advisability of continuing pumping operations. His investigations, covering a period of several weeks, and conducted with unusual care in securing data on the subject, lead him to believe that the volume per vertical foot, as indicated by the various records of the pumping mines, and the flow of water from the two tunnels—the Moffat and Standard—which greatly aided the drainage, varied from a maximum of 107,000,000 gallons to a minimum of about 40,000,000 gallons. He was inclined to believe that the volume of water showed signs of diminishing quantity per foot as depth was gained, although the greatest amount was indicated as existing some 40 to 50 feet above the present water level.

Assuming that 40,000,000 is approximately the number of gallons per vertical foot, the cost of unwatering the next 100 feet over the district would be as follows: Forty million gallons, at 8½ pounds per gallon, equals 166,666 tons; taking the rate of 4 cents per ton of water pumped, as is estimated to be the average Leadville cost for a similar average height to be pumped, this would imply \$666,660 as the cost of pumping out the next 100 feet, and, as pumping works by a sort of inverse ratio, the cost going up as the shaft goes down, there would need to be a very large decrease in the quantity of water to be pumped before taking off very much from these figures.

The committee having in charge the negotiating with the various mining companies for funds sufficient to complete the first tunnel have had a great many difficulties to contend with, the principal one of all being the indifference of many of the mining companies, whose property will be benefited and greatly enhanced in value when drained to great depth; all of them are perfectly willing that the tunnel should be driven, but preferably at the expense of others, and they have generally taken a very narrow view of the situation.

Can any one doubt that the driving of even this first tunnel will not give a new era of prosperity and an added value to every mine on the west side of the district which has a vein on their property—that the very fact that many of the former dividend-paying mines that have freely expended hundreds of thousands of dollars in draining the water to its present level will be again able to resume dividend paying—

that this will not give an added impetus to mining in Cripple Creek?

Why should there be such a strange hesitancy in doing what everyone is persuaded is the right thing to do? Why delay month after month in beginning action when everyone knows that the non-solution of the water problem is the only cause for the present state of depression, not only in the mining stock market, but in actual mining operations in the camp as well?

The Mining Industry of the Cœur d'Alenes, Idaho.*

NUMBER III—CONCLUDED.

By J. R. FINLAY, Colorado Springs, Colo.

USE OF WATER POWER.—All the mines make more or less extensive use of the water power of the region. An enterprise is now on foot to supply any deficiency of power by means of a 90-mile electric transmission from Spokane Falls. It is expected that, in view of the high cost of coal, this will prove cheaper than steam power. Practically all the power from the neighboring streams is now utilized for running mills, generating electric power and compressing air.

At three of the principal properties elaborate water power plants have been installed, but, by reason of the variation in the water supply during the year, each plant is, to a greater or smaller extent, supplemented by steam power.

At the Tiger-Poorman mine, on Canyon creek, electric power, generated by water power, is used for pumping on a large scale. The pumping station is more than 1500 feet below the surface, and the pumps raise the water through that distance in one lift. The plant consists of two independent pumps, which can be run either by steam or electricity, or both. The steam engines are 18x30x36 inch cross-compound condensing engines. The electric motors are each 200 H. P., alternating, 40-cycle, induction motors, using a current of 2300 amperes, which is brought down the shaft to the machines by a 2½-inch submarine cable. The pumps are geared, have 4½x36 inch plungers, and flywheels 16 feet in diameter, which carry 30-inch belts. These pumps have effected a vast economy in the operation of the mine. They raise from 400 to 1200 gallons (averaging about 500 gallons) of water per minute.

The Morning Mining & Milling Co. employs in exploitation a well-planned power system, most of which is used for making compressed air. The water is gathered from various streams high up on the mountains above the compressor site, and conveyed to the wheels by three pipe lines of 1400, 1200 and 140 feet head, respectively. The 1400 and 1200-foot heads are delivered by separate nozzles on a Pelton wheel 32½ feet in diameter. The 140-foot head is used to drive two 11-foot Pelton wheels, one on each side of the big one and on the same shaft. There are two compressors, one on each end of the water wheel shaft. They have 18x32½x42-inch cylinders, with intercoolers. The air is compressed to 28 pounds in the low-pressure cylinder, and delivered by the high-pressure cylinder at 90 pounds. Running at full speed, these machines compress about 6000 cubic feet of free air per minute. The pipes which convey this air to the mine cost more than the machinery. They comprise 9200 feet of 12½-inch pipe to No. 6 tunnel, at which point the air is divided into two lines of 9-inch pipe, one entering No. 6 tunnel, which will be 2 miles long, and another leading 4½ miles to No. 5 tunnel.

The Bunker Hill & Sullivan Mining & Concentrating Co. also uses water power to help run its large compressor at Kellogg.

MILLING.—The process employed is substantially the same at all the mines, and consists of coarse crushing and separation by jigs. Most of the ores contain the galena in segregated streaks of practically clean material, which separates under crushing and is easily caught. The difficulty increases greatly when the galena is intimately mixed with iron carbonate, zinc blende and quartz. Such ores require much finer crushing and the use of a greater number of vanners, buddles, shaking tables, etc., to separate the slimes. The following description of the process at the Standard mill will serve as a concrete example of the best current practice:

The crude ore from the mine is dumped from railroad cars into a bin of about 600 tons' capacity, whence it is fed by gravity to a No. 5 Gates crusher, which reduces it to something over 1 inch diameter. From the crusher a 15-inch belt conveyor carries it to another bin, whence it passes by gravity to the roughing rolls, which reduce it to pieces of ½ to ¾ inch diameter. From the roughing rolls it is elevated to a double set of trommel screens, which size it into an "oversize" of more than 15 millimeters diameter, and into sizes which pass through 15, 10, 7 and 3-millimeter screens. The fines which pass the 3-millimeter screens are not jigged, but go at once to V-hoxes or hydraulic classifiers. The slimes passing over the V-hoxes go to settling tanks, where the heavier material is caught and sent to Wilfey tables and Frue

vanners. All the tailings from tables and vanners, together with the overflow from the settling tanks, go to a "canvass" plant of fifty-two tables of 6 square yards each. Material caught on the canvass tables is reconcentrated on two Wilfey tables.

Returning to the coarse material classified by the trommels, the oversize—or what passes over the 15-millimeter screens—goes to the coarse or "hull" jigs, and what passes through the 15, 10 and 7-millimeter screens goes to finer jigs.

Part of the tailings from the coarse jigs is retained as "middlings," to be further treated, and part is allowed to go directly to the creek as worthless. The middlings thus saved are passed through fine rolls and then to Huntington mills, which reduce the pulp until it passes a 40-mesh screen.

The finer jigs—i. e., the 15, 10, 7 and 5-millimeter jigs—also select a percentage of the middlings, which are likewise passed through fine rolls, in three sets, according to the coarseness of the material. Thence this material passes to the middling jigs, which take out some clean ore. All of the tailings from these middling jigs are reground in another set of Huntingtons to 40-mesh. All the material ground by the Huntington mills goes to the Wilfey tables and Frue vanners with the slimes from the settling tanks and V-hoxes above described.

This mill concentrates about 500 tons of crude ore per day. Its machinery consists of the following: A No. 5 Gates crusher; two 15-inch belt conveyors; six sets of 15x26-inch belt rolls; four 5-foot Huntington mills; twenty-eight Hartz jigs, arranged in fourteen pairs; two lines of trommels; an "oversize" trommel for middlings; four elevators; eighteen Wilfey tables; three 4-foot Frue vanners, and fifty-two canvass tables.

Power for the main mill is derived from two Pelton wheels, one of 4 feet diameter under a 32-foot head, and one of 6 feet diameter under a 235-foot head. A third (24-inch) Pelton, under a 235-foot head, runs a dynamo for electric lighting, and a fourth runs the Gates crusher.

TRANSPORTATION.—The transportation of crude ore to the mills is a problem of considerable importance to all the mines except the Tiger-Poorman, the Frisco and the Crown Point, each of which has its mill at the place where the ore reaches the surface. The ore from the Standard, Hecla, Mammoth and Empire State is hauled to the mills by the Northern Pacific and Oregon Railway & Navigation Co. railroads, which reach the mines, and do the work for a reasonable price. The Bunker Hill & Sullivan has a Bleichert tramway about 2½ miles long. The Morning Mining & Milling Co. has a railroad of its own, several miles long, built on a 7% grade, and operated by means of Shea geared locomotives. It has proved very successful, hauling the ores to the mill for less than 10 cents a ton, inclusive of delivery of all timber and other supplies to the mine.

The cost of transportation varies from 8 to 20 cents per ton at the various mines.

PROGRESS AND PROSPECT OF DEVELOPMENT.—It is reasonable to expect that the Cœur d'Alene district will be able to maintain its present—and perhaps an increased—output for many years to come. Within the past two years three new properties have been opened up and brought to the dividend paying stage, while several others have shown more or less ore, and are likely to develop satisfactorily.

The Hercules, which is the latest discovery of great importance, promises to become a mine of the first rank. This vein is at the upper end of Canyon creek, high on the side of Tiger peak. Near the surface the lead values have apparently been destroyed by leaching, but at the depth of some 400 feet the ores are found to be very rich both in lead and silver. This is a good instance of that reconcentration of values near the surface which is beginning to be recognized by students of ore deposits as an important feature in the value of many metal mines.

Up to date the Hercules has not reached the point of concentrating its ores, but ships them crude, at a handsome profit.

In the Mammoth mine the ore almost invariably lies in a single streak in immediate contact with the fissure. The shear zone is much narrower than elsewhere, and the mining is simpler, in that no filling on an extensive scale is required. All the material broken is sent to the mill as concentrating ore. The timbering consists entirely of stull sets, with 6-foot posts, instead of 8-foot, as in the Standard. The chutes are built of planks, instead of the cribbing which is necessary when the stopes are filled.

At the Tiger-Poorman, Hecla, Frisco and Morning mines all the stoping is done with stull sets, about as in the Mammoth. Very little effort is made to sort the ore before concentrating, or to fill the stopes systematically. It is an open question whether it would not pay better to give more attention to sorting and filling, and less to timbering. With closer sorting the concentrates might be obtained by the milling and transportation of less material, and, as an additional advantage, the stopes would be left in a safer condition.

THE eighty-third meeting of the American Institute of Mining Engineers, being the thirty-third annual meeting, will be held at Albany, N. Y., beginning Feb. 17, 1903.

Relation of Apex and Side Lines in Locating a Claim.

Although the United States statutes usually state clearly the requirements of law in the matter of locating, holding and patenting mining claims, it seems to have left some in doubt as to their rights in the matter of the relation of the apex to the side lines. The following is in explanation and answer to a question of an Arizona correspondent: A locates a claim and takes the full statutory dimensions—600 feet by 1500 feet—but for reasons probably satisfactory to himself takes 100 feet on one side of the discovery point and 500 feet on the other side. Subsequently B, noticing this unusual proceeding, encroaches upon A's claim, and appropriates 200 feet by 1500 feet of it to form a portion of a new claim. The relative position of the conflicting locations, the position of the discovery shaft, and course of the outcrop of the vein are indicated in the accom-

panying sketch. The claims are laid out in an east-west direction, the dip of the vein being to the south. B's claim is indicated by the dotted lines, showing encroachments upon the claim as staked by A.

A's discovery point is seen to be at the extreme east end of his claim and to be upon the apex of the vein. The question arising is, did A make a legal location and can B legally dispossess A of a portion of his claim?

"Lindley on Mines" says, Sec. 364: "There can be no question but that the Act of July 26, 1866, as well as all subsequent legislation by Congress, contemplates that the location shall be made along the course or strike of the lode." And in Sec. 366 the same authority says: "The primary function of the side lines is to connect the opposite extremities of the end lines, and to complete the enclosure of a surface within which is found the apex of the discovered lode. As the width of the location is fixed with reference to the middle of the vein, the law contemplates that this must be ascertained by actual exploration and development, and cannot be assumed to be in an unexplored position."

"Where the vein outcrops at the surface there can be no question as to the point from which the lateral measurements must begin. When the discovery shaft develops the vein at some distance below the surface, and the locator does not determine by any further development that the nearest actual surface point is elsewhere, and the fact does not otherwise appear, the land department has ruled that, for executive purposes, the middle of the vein as disclosed in the shaft will be assumed to be the point from which lateral measurements are to be calculated."

Then follows a paragraph having a direct bearing on the question in point. It reads as follows:

"According to the regulations of the department, lateral measurements cannot extend more than 300 feet on either side of the center of the vein. Hence 400 feet cannot be taken on one side and 200 on the other; but if, by reason of prior claims, the full width allowed cannot be taken on one side, the locator will not be restricted to less than 300 feet on the other."

It is evident from the above that A did not make a legal location, and B had a right to take for himself all that had been taken by A in excess of 300 feet on the south side of A's discovery shaft. The law does not presuppose a prospector to be a civil engineer, and requires him to so locate his claim that his side lines shall be at all times about 300 feet distant from the center of the vein. Owing to the dip of many veins, and the uneven topography of the country, this may necessitate an elbow in the claim, but this is permissible if the end lines are parallel. The law permits the locator to have 1500 feet along the strike of a lead, the distance being measured horizontally, and does not require that the measurement be made along the line of a sinuous outcrop.

A's claim will stand 400 by 1500 feet, he losing the additional 200 feet on the south side, but it is not apparent that this loss will in any manner affect the value of the location in so far as it refers to the vein upon which discovery was made, as A is entitled to extralateral right and can mine his vein to his south side line and underneath B's location—and beyond, if he cares to. It is presumed that B also has made a discovery of a vein on his claim. Should B's vein by reason of steeper dip be found to unite with A's vein in depth, A would take both below the point of convergence, as A's location is senior to B's.

Stamp Milling and Amalgamation of Free Gold Ores.

Written for the MINING AND SCIENTIFIC PRESS by DANA HARMON, San Francisco, Cal.

I have been asked to revise and amplify a paper on stamp milling which I read before the Technical Society of the Pacific Coast in September, 1900.

It has never been my intention to write a text-book on milling—the field has been well threshed—but merely to reduce to writing some of my own thoughts and experiences in the hope that out of it some profit would spring to me at least. The very act of writing benefits by crystallizing the, perhaps, vague thought into concrete expression, and discussion does of itself tend to clarify. I had my own grave misgivings. Could anything new be said? There was no gain in giving the old ideas a new dress. From one point of view talk seemed idle—a species of assault and battery on the other man's good nature. Millmen are usually sure they are doing the right thing. But travel will prove up all sorts of methods, much guessing and rule of thumb, ruts deep and many. Experimenting has caused me to change methods and so may it, too, other men.

After weighing the matter, the best course seemed to be not to argue out all the details, but to whittle close, and yet to give some reasons. It is very clear to me if we could get a series of papers from the busy superintendents who are actually doing and studying, telling us what they are doing and why, that there would in a few years be built up a valuable literature on milling. The thought and effort of one man would stimulate another, so that in the long run the superintendents and also this now respectable business of mining would be benefited.

It is not at all the literary man—his text-book, or his account of everybody's work, with no sorting out of the good from the bad—that we are in need of. Let those who can get out in the open and give us a plain tale from the hills. The superintendents will come near turning out the genuine article. They are not academic. The chronicler must always precede the historian. Let the superintendents tell us what they are doing and let each read the other man's story.

Gold mining is the only business where it is impossible to offset increased costs of production by adding to the price of the finished product. It never suffers from competition, but it does suffer from ignorance as to what its traffic will stand, and from incompetent management. Fear of competition holds back many a manufacturer from disclosing his trade secrets. But in gold mining there can be no such fear and free discussion advantages all.

Quite as important is it to catch the gold as to find the ore. In these low-grade days a superintendent should be a milling man as well as an underground man. Mining has gotten down on all fours with any other business. To the capitalist there is no essential difference between a cotton mill and a quartz mill. The girl at the loom does not run the loom. No more should the battery boy decide how to amalgamate his ore. A superintendent should not have to run to and fro hunting for a "good millman"—he should be able to make one out of raw material.

In the smaller mills (not over 100 stamps) the actual load at the mine, both underground and on top, is upon the shoulders of the superintendent. When working on close ore margins, the difference between dividends and failure will turn upon the skill of this one man, who knows the ins and outs of every phase of his business. Many of the millmen, standing their twelve-hour shifts, are doing conscientious and excellent work. But it is not to be expected that these, toiling hard every day and tired out at night, can find time to study, to think, to compare. This is the duty of the superintendent. Daily toil, iteration and reiteration, dwarfs and dulls the human brain. Small wonder that so many millmen are "set in their ways." Rightly have these men disregard for the opinion of a superintendent who is manifestly beyond his depths in the mill building, and who can only fume over a poor cleanup. These same millmen will accept new methods from a live superintendent, who they can see is trying to reach the best results. The West is full of superintendents who don't know as much about the mill as they should, who are content to draw salary but won't think.

We learn to discard notions which were once holy as though from the Koran. Out of the din and hammer of the stamp mill there has come to me certain definite conclusions touching mortars, tables, mill construction and amalgamation. I believe that there are certain fundamental principles which underlie the treatment of all ores falling within the lines of my caption. The local variance which must be had for ores of different districts are mainly those of screen and water, matters determinable by assaying the tailings.

CONSTRUCTION.—Without going into the details of mill construction it may be well to note some points bearing upon the work to be performed. Millwrights are seldom millmen, and it will usually occur that the \$10 millwright will set small store upon the opinion

of the \$3 millman. Too much stress can not be laid upon the necessity for substantial work, especially on heavy stamp mills.

MILLSITE.—A millsite should be selected so as to permit: (a) plenty fall from track to concentrator floor (60 feet will do but 90 is safer); (b) straight-line tracks if possible, certainly no sharp curves; (c) additions to mill readily made.

There is often economy in original construction and also in operation by banking the mill directly against the mine head gear. But this is poor economy. In some States, on account of the danger from fire, the law wisely forbids buildings at the mine opening, so as to avoid the danger from suffocation underground.

It is also cheaper to put the rock breakers inside the mill building, but it is a vicious practice. Rock breakers make dust and should therefore be entirely separated from the mill building. The question of dust on the cams is worth considering. It will be found that with the same power applied to the line shaft, stamps dropping say ninety-three per minute in the morning, immediately after oiling up, will drop eighty-seven to ninety in the afternoon owing to dust on the cams and bearings—this dust arising from running rock breakers inside the mill building. This difference will vary as the ore going to the breakers is wet or dry. It may be noted in passing that clean quartz from even a wet stope is dry enough to throw out clouds of dust from the breaker.

Another point is the slope of the ground at the millsite. It is not always practicable to have exactly what is best. But a little foresight will save expense in the long run. A 20° slope fits well, gives minimum grading costs, and insures plenty of light behind the batteries. Having a choice between 15° or 30°, take the former. A level plain is not bad—necessary if it is a large mill with batteries back to back. The expense of elevating crushed ore to the bins by skip or belt conveyor is trifling. Upon ordinary mountain roads a 5-foot cut at the back finds solid rock or stiff subsoil. This is just about what a 20° slope affords.

A 20° slope will minimize the grading by having a 5-foot cut at the back line of the concentrator floor. This insures solid foundation for the wall usually erected between the battery and concentrator floors. With a rock outer wall the intervening space of the concentrator floor can be rock filled and finally cemented.

Where the pulp is to pass from the tables to the concentrators, the vertical distance from the lower end of the battery floor to the concentrator floor should not be less than 22 feet. This is a detail often overlooked. It is always best to have a classifier before the concentrators, and some of these require 12 to 14 feet head room. Moreover, launders use up grade fast at the rate of 1½ inch per foot.

BACK KNEE FRAME.—I prefer the back knee frame because of its solid bracing to the ore bin, the tapets are in plain sight, the pull of the belt is downward, it requires less lumber, and the plates are well lighted. A flat bottom ore bin will strengthen the anchorage and bracing of the battery frame. True, it retains constantly a large quantity of rock; but it is a phenomenal mine that does not yield enough poor ballast. The constant slide of ore on a sloping bin bottom tends to crowd the entire structure forward.

One objection that the line shaft is subjected to dirt need not be. Set the base of the mortar 6 feet above the top of the mudsills, instead of 3½ or 4 feet, as is customary with contractors. This will give plenty of head room around the shaft and pulleys. Tight wood boxes encasing the shaft for its entire length will keep out dirt, and will minimize the danger of accident to the man oiling the bearings. Plank or cement this mudsill floor. Whitewash every post and wall; oil cups on bearings. We often see a ¼-inch pipe leading from the feeder floor down to the shaft boxes. This is a lazy man's folly.

In figuring on power the uncertain factor is friction, and if bearings are to be saddled with dirt and gum, as in the dark they surely will be, power is wasted. There is a good bit of the personal equation in friction. A more serious objection to the placing of the line shaft—as is ordinarily done in back knee frames—underneath the feeder floor is the heavy strain on the cam shaft belt. This causes frequent delays to relace the belt. On this point note a suggestion below, which seems to me practicable, viz., rope driving.

MORTAR BLOCKS.—There are still radical differences of opinion as to the relative merits of concrete or wooden mortar blocks. The use of concrete is increasing, but it is undeniable that there are instances where the concrete has been blown out and replaced with wooden blocks—replaced either because the concrete crumbled or induced excessive crystallization of nuts, bolts and stems. It is not possible to ascertain the exact cause of failure. It may have been faulty construction. Nobody cares to talk about his failures, and it is but human nature that the superintendent will not be eager to fling out upon the outer wall any extra editions reciting his repair tribulations. One man would save an excavation by building up a concrete pier set practically on top of the ground. Another would save on quality of cement. The third—a novice at mixing—would put in the concrete too dry, relying upon tamping, and therefore

inevitably left fatal interstices in the mass. So that, while it may ultimately be proven that concrete is the best material for a mortar block, nevertheless with it, as with wood, the details of construction must be carefully worked out. It took years to find out that vibration tends to move the wood block mainly in a direction parallel with the line shaft. The wood block must not only be set on a firm base, but it must also be tamped all around with the utmost care, so as to keep it in place.

It has been the custom to insert a gasket between the mortar and the wooden block—rubber, canvas, blanket or paper. In the earlier concrete blocks the same practice was followed. Probably, when analyzed, the value of the gasket lay in the protection it afforded to the wood. It was put in as a cushion for the mortar where none was needed, but it operated practically and, without our realizing the fact, merely as a protector to the wood. Concrete does not need such protection. Logically, if one builds of concrete there should be no gasket under the mortar. At the North Star mill the mortar rests directly upon the granite cap, without any gasket, and the superintendent reports the mill working with entire satisfaction.

All things considered, the concrete block may be said to be in the evolution state. It does not rot. Neither does a first-class wooden block short of twenty years. This cement block will be improved. There have been already enough failures with them to teach the lesson that they must be constructed with care.

Anchor bolts 6 to 8 feet long, instead of 30 to 40 inches; the base of the mortar wide enough to admit of the bolt being inserted after the mortar is in place; pockets in the concrete so that a new bolt can be slipped in; cast iron cups to receive the battery posts, set on a level with the bottom of the mortar (see North Star mine plan as shown in the MINING AND SCIENTIFIC PRESS for March 22, 1902); a cap piece to the concrete is advisable and granite is cheaper and better than cast iron; the concrete must be laid in wet, so that the voids will be filled (this is an especially important point); use only the best of Portland cement; three parts sand to one part cement will give a strong mortar for rubble masonry, and also for broken stone concrete on all except the top layer, when the proportion should be changed to two of sand to one of cement—these are some of the points which readily suggest themselves. Weighing, now, the whole question, my own conclusions are as follows:

First—The chief objection to the concrete, that its rigidity induces excessive crystallization, can be overcome by a composite block—concrete to the ground line and capped with wood. It would be durable, permitting renewal of the woodwork at reasonable expense. The great advantage of the concrete block is that the mill can stand idle without deterioration, which most decidedly is not true of the wooden block.

Second—The jar of a 1100-pound or 1200-pound stamp is so much greater than that of an 850-pound stamp that one should not assume certain success for the former based upon a concrete success on the latter.

Third—A sufficiently durable wooden block can be constructed. I have never heard of one being blown out because it had failed to turn off good work.

Fourth—For every mine the local conditions should control the choice. Costs of material, the probable life of the mine, etc., should be considered. There is no use of an everlasting foundation on a ten-year mine.

Fifth—A potent cause of crystallization is due to bad construction of battery frame, posts and sills. With any block there should be especial attention paid to this frame construction. There is no wisdom in putting a house carpenter at framing battery timbers. Carpenters are all right on the mill building.

(TO BE CONTINUED.)

What Is Steel?

We are all familiar with the name, but how many of us if asked this question could answer with any degree of certainty? It is necessary to define the term "steel" at some length, since the old classification very inadequately describes the modern cast, malleable compounds of iron, carbon and metalloids used for structural purposes and constituting at least three-fourths of the metal now made by steel processes.

The old term "steel" referred to the cast malleable product of iron and so much carbon that the metal would harden when beated to redness and thrust in water. The homogeneity of the metal is, however, an equally distinguishing quality, and is due to its having been poured into a mould when in a fluid state, so that the slag might separate by gravity, and the metal might become solid and crystalline.

Wrought iron, on the contrary, while having similar chemical properties, and sometimes as much carbon, consists of pasty masses from which the slag is rarely quite expelled by the pressure that sticks them together. It is, therefore, laminated in structure.

As the soft compounds and those varying in chem-

ical constituents came gradually to be produced by casting processes, it was natural and convenient to enlarge the term "steel" to cover them, and the use of the term was at the same time rendered legitimate and scientific by basing the classification on one of the grand characteristics—structure due to casting—rather than on ingredients, as heretofore, especially since structural qualities were constantly increasing in importance. It has been found practically convenient to distinguish between all the cast malleable compounds, whether hard or soft, by affixing the name of the metal incorporated, such as chrome steel, manganese steel and the like, or the percentage of carbon, or both. It is important to know the amount of carbon in structural steel, and this is readily determined.

It will thus be seen that the grand structural characteristic of steel to which it largely owes its value for all uses is homogeneity due to fusion; also that its chemical constituents and characteristics due to them are various.

The important chemical qualities of tool steel are: First, the tempering quality, which is due to the presence of 1% to 1½% carbon and its mechanical mixture with the metal by means of slow cooling from red heat. This makes the metal comparatively soft, so that it may be cut by ordinary tools, but upon reheating and suddenly cooling it becomes extremely hard, owing to the carbon remaining chemically dissolved in the iron. Second, freedom from such ingredients as phosphorus and sulphur, which induce brittleness.

Except some modern steels in the manufacture of which nickel, manganese and the metalloids are employed, the best tool steels have but a few hundredths of a per cent of any other ingredients except carbon, silicon and iron.

The terms "pot steel," "crucible steel," "Bessemer steel," etc., are used only to distinguish processes of manufacture, and do not necessarily differ chemically or mechanically.—G. E. Wolcott in *The Aurum*.

The Terlingua Quicksilver Deposits of Texas.*

Written by B. F. HILL, Geologist.

Within the last five years a new industry has sprung up in Brewster county, Texas, which has added materially to the value of the output of metals from that State. Reference is made to the quicksilver mines of the Big Bend of the Rio Grande, in the southwestern part of Brewster county.

The belt that may be designated as mineral bearing is approximately 15 miles long and 4 miles wide, the greatest length being east and west.

While it is not probable that all the paying mines will be found within this area, it will be within this district that nearly all the development of the near future will take place.

The rocks of the area may be divided into two classes, those of sedimentary origin and those of igneous origin. The rocks of the igneous class may be subdivided into those which came into their present positions in the molten state and those which, though of igneous material, have been laid down in beds, as volcanic ash and tuffs. These latter are important only on the outskirts of the district.

Except for minor unconsolidated deposits of recent origin, all the sediments in the district are marine, although they indicate that the conditions under which they were deposited varied to a considerable extent, as there are deep sea and shallow water deposits, with many intermediate varieties.

The sediments belong to two periods, the Cretaceous and the Tertiary. The Cretaceous section is extensive, and has representatives of both the Upper and Lower divisions. The total thickness of the Cretaceous is in the neighborhood of 2000 feet, while the Tertiary, with the volcanic tuffs and ashes, represents several hundred feet more.

THE IGNEOUS ROCKS.—In three localities upon the Terlingua uplift the igneous rocks cut the Lower Cretaceous limestones. In two of these instances, that of California hill and Clay mountain, in the vicinity of Terlingua postoffice, they occur as old volcanic plugs, whose upper portions have been eroded. Both these plugs are flanked by the limestones and shales of the Buda and Del Rio formations. These rocks have been locally metamorphosed on the contacts, slaty cleavage having been induced in the shales. The third instance of volcanic material within the bounds of the uplift is that at Black mesa. It is probable that here the volcanic material never penetrated the Lower Cretaceous, as in the cases mentioned, but formed a laccolite between the Edwards limestone and the overlying beds. Black mesa owes its existence to this intrusion.

A common type of structure in the Upper Cretaceous area of Terlingua creek valley is the lava capping of the sediments. In some instances the mass of lava upon the sediments is several hundred feet thick. It is in the capping that the only quicksilver in igneous rocks has been found.

The rocks most commonly encountered belong to

two strongly contrasted groups, viz., a series of basic basaltic rocks and a more extensive series of acidic rocks, including phonolites, andesites and rhyolites.

RELATION OF VOLCANIC ROCKS TO THE DEPOSITS.—Although the existence of the deposits of quicksilver depends on the presence of volcanic rocks, the relations are indirect. The deposition of the ore was dependent on the presence of hot springs, which were undoubtedly caused by the volcanic rocks. As pointed out by Prof. Becker (Monograph XIII, U. S. G. S., p. 417), such springs are most likely to occur at a very moderate distance from lava, but several miles may intervene. In the Terlingua district all the deposits are within a short distance of volcanic rocks of some nature. In only one case is the cinnabar actually associated with the volcanic rock directly, but its deposition undoubtedly took place subsequent to the flow of the volcanic material.

THE ORE DEPOSITS.—The mining operations that have been carried on in the Terlingua district have been practically all on the surface. The ore has been found along certain lines that bear definite relations to the structure of the rocks, and in masses that seem to have no visible definite relationship to the rocks or to other deposits. There are distinctly defined calcite veins that contain large quantities of quicksilver ore, while contiguous parallel veins of precisely the same general character may not carry a trace. Masses of brecciated limestone and iron-stained clay material may carry large quantities of cinnabar or may be completely devoid of it. The position of the

thread and spread out several feet. The cinnabar is generally near the center of the vein, but stringers extend not only through the calcite to the walls of the veins, but sometimes for short distances into the country rock.

The iron associated with the calcite and cinnabar in the fissure veins is always in the form of the oxides, when the wall rocks are the Lower Cretaceous series. In no instance was undecomposed pyrite found in veins in these formations when cinnabar was present. Veins in the Del Rio clay often carry considerable pyrite, but no cinnabar is present, nor does a careful analysis of the masses of pyrite reveal the presence of the metal. The oxides are both limonite and hematite, crystalline and amorphous. They are often accompanied by oxides of manganese. The fillings of the fissures are generally confined to these materials. Sometimes, however, masses of clay are encountered in the vein. The clay often contains finely divided native mercury, but more often it is barren of the metal.

METHODS OF MINING.—The methods of mining employed in the Terlingua district have been up to the present simple and crude. The machinery in use is confined to picks, shovels, drills and sledges. Windlasses are used in the shafts, few of which are over 20 feet in depth. The deepest shaft in the field was about 80 feet in August, 1902. The material was hoisted to the surface in rawhide huckets upon the backs of the Mexican miners, who climb the notched poles or chicken ladders with great agility.

The location of the vein is generally determined by

Banded Structure in Ore, Terlingua, Texas.

deposits is influenced by the system of faults already mentioned.

The deposits in the neighborhood of Terlingua postoffice, which include the workings of the Marfa & Mariposa Co., the Terlingua Mining Co., the Colquitt-Tigner Co., and numerous small prospects belonging to various companies or individuals, are all in the limestones of the Upper Cretaceous.

FISSURE VEINS.—There are several types of deposit carrying the quicksilver ore in the Terlingua district. The most usual one is the vein filled with calcite gangue carrying cinnabar and the iron oxides. These fissures are of variable width and linear extension, but taken altogether are the most persistent of all the forms of deposit. The veins of this type are in two systems, having courses at right angles to each other. The northeast-southwest veins are the most productive of quicksilver, those normal to this series rarely carrying even a trace of the metal. In most cases the fissure is practically vertical, although slight dips have been observed.

The filling of the vein is largely calcite. Usually a distinct banding arrangement is visible, the bands differing in color, size of crystals, and amount of iron and cinnabar present. Generally in the calcite veins the cinnabar is in crystalline aggregates, but amorphous masses are sometimes present in connection with the crystalline variety. Vugs frequently occur in this type of vein. A common variety is made up of an exterior shell of limonitic material with an interior lining of calcite crystals, generally of the dog-tooth spar variety. The crystals of spar are thinly coated with small crystals of cinnabar, causing the appearance of solid crystals of cinnabar. In no case has the cinnabar been found actually crystallized within the calcite, but the calcite crystals are often filled with iron-colored material.

From the Excelsior vein masses of almost pure cinnabar weighing several hundred pounds have been taken. The veins are by no means uniformly rich. Often the ore-bearing streak may diminish to a

trial workings of surface material in a horn spoon.

After the cinnabar has been found in a vein its course is traced by shallow pits along it, from which washings are taken. The veins are generally narrow, often less than 1 foot. But, whatever the width, the usual custom is to excavate a pit from 3 to 8 feet in width along the course. Portions of the excavated material showing cinnabar are thrown into separate piles, according to the apparent richness. In the open cuts along the veins one object has been the opening up of the ore to sight. In view of the irregularity of the deposits, and the liability of the ore to disappear, this method has been a useful one. The deposits are assumed to continue in depth, but no important attempts have yet been made to prove it.

In addition to the open cut method of following the vein, the ore is obtained by the method of drifting along the course of the vein from the shallow shafts. Tunneling has been carried on in a few instances where the topography has been favorable, but a large proportion of the ore has been obtained from workings open to daylight.

(TO BE CONTINUED.)

In metallurgy electrolytic solution processes are in use or on trial for the more valuable metals, such as copper and nickel. The reaction between chlorine and metallic sulphides at high temperatures brings the whole domain of sulphide ores under sway. Thus a sulphide, say argentiferous galena, is treated with chlorine, which gives off the sulphur as sulphur, which is condensed and sold, the lead uniting with chlorine, making chloride of lead. The silver is extracted by stirring with a little lead, and the fused salt is then electrolyzed, yielding pure desilverized lead and chlorine. The process is self-contained, yielding sulphur, lead and silver. It is especially applicable to mixed refractory ores which have been nearly valueless, though plentiful. These reactions have been proved on the large or ton scale, and there is no technical difficulty.

*Extract from Report of B. F. Hill in Bulletin No. 4, University of Texas.

Steam Shovel Excavation in San Francisco, Cal.

Written for the MINING AND SCIENTIFIC PRESS by
R. P. McLAUGHLIN.

During the past year excavation has been carried on by the Santa Fe R. R. Co. in the vicinity of the China Basin, San Francisco, Cal. Nearly the entire eastern half of a hill has been removed by a cut. The highest bank is 175 feet, the length of cut a quarter of a mile, and the average width about 600 feet. The total volume to be extracted is approximately 1,500,000 cubic yards.

The material to be moved is what is locally called greenstone. It is much faulted and crushed, being mostly serpentine and altered rock. The only breaking process to which it is subjected is that resulting from blasting, which seldom leaves pieces greater than a cubic yard in size.

The shots are placed in holes 10 to 15 feet from the edge of the bank and about the same distance apart. Dynamite is the explosive used. Drilling is accomplished by steam power. Three portable boilers furnish the pressure. Coal is the fuel used by all the boilers on the work, with the exception of one, which uses oil. The steam is carried by 1½-inch pipe to a power drill using an X-shaped bit. Two men attend the boiler and steam and three are required to move and set up the drill. The blasts do not interfere with other work, simply caving the bank and scattering little debris.

The cut has been made in three steps, the shallowest being on the upper side of the excavation. A steam shovel works in each of these smaller cuts alongside a temporary track. The shovel stands on a short track which is extended forward by 8-foot lengths as the bank is cut away, the track being removed from behind as the machine advances. This track is laid on the ground or upon cribbing as occasion demands. A half circle of about 15 feet radius represents the area cut away by the shovel at one setting. In operating the shovel three men are required. One controls the raising and side swinging motions of the scoop, another lengthens and shortens the arm to suit the depth of the cut, or the distance to the bank, and also opens the bottom of the scoop for dumping. The third man acts as fireman. Several men are employed to clear obstructions from the track and move the shovel.

Two trucks similar to those of an ordinary freight car carry the shovel. Side displacement of the forward truck is prevented by tension braces fastened to the platform, and to foundations set about 4 feet from the track, and an equal distance in the ground. The tendency of the shovel to be pushed back is resisted by locking back of the wheels, and by clamps fastened to the rails back of the forward wheels.

The machines used are of three sizes, viz: forty-five, sixty and eighty tons. The largest machine is used in the upper cut, the smallest in the lower cut, the third machine doing duty in the middle cut. The capacities of the dippers of the three shovels are respectively 3½, 2½ and 1½ cubic yards, and average amount of earth removed per ten-hour day by each is 2000, 1500 and 1000 cubic yards.

The 65-ton shovel is fitted with a 25 H. P. boiler and has two engines attached, the larger engine of which does the lifting and swinging, the smaller doing the thrusting.

The "greenstone" has proved to be very trying on shovels, frequent repairs and reinforcements being necessary. The scoops are of steel, the body plate of the 65-ton machine being 1½ inch thick and the several points about 6 inches square. These parts have been badly worn, and almost entire renewal of the scoop has been necessary. Frequent renewal or reinforcement has been needed in the beams and bracing of the forward parts of the machines.

The excavated earth is hauled about a mile by rail to where China Basin is being filled for railroad yards. Five trains have been in use. Grades are often uneconomical, owing to their having to conform to those of the streets along which the track runs.

Two styles of cars are in use, wooden and steel. The former are the smaller, having hoxes about 10x10x2 feet, being mounted on four wheels. These cars dump by the releasing of a chain on one side which allows the box to tip to the opposite side. The righting of these cars can be done by hand when empty. A train of these cars usually comprises sixteen cars with a flat car partly loaded at the end. The latter serves to ballast the train, and also acts as a brake, none of the small cars being provided with them. The lightness of these cars necessitates the track being kept clear of rock which falls from the cars during loading. The chief advantages of the wooden cars are low cost, durability and ease of repairing. They are unprotected by patents. These advantages seem to make the cars best fitted for this sort of work.

The larger cars are of steel and are 30x10 feet. Their weight is about twenty-five tons and the carrying capacity stated to be forty tons. Usually eight cars are taken in a train. Air is the power used for dumping, and also for the brakes on each car. The car is divided by a cross partition into two compartments. The dumping gear is arranged to allow any or all sections of the car to be dumped at

once. The bottom of the car is formed by swinging sections which meet at the center of the car and are drawn to place before loading by a steam derrick. The plates slope down over the trucks from the pointed bottom, forming a guide for the falling earth during dumping. This shape of car raises the center of gravity of the load higher than in a flat car with similar trucks. The strain on the trucks is consequently great, and on rough temporary roads, such as are here used, breakage of wheels is frequent.

The steel cars have not proved best suited to this work, as necessary repairs are frequent, more troublesome and costly than on wooden cars.

Another excavation of less magnitude is being made by the Southern Pacific Co. on the western side of the hill. One small steam shovel and considerable hand labor is employed. The earth is hauled a quarter of a mile to the north by gravitation. The system used is simple and its application elsewhere may prove of value to mining men.

The cars have hoxes of 2-inch planking about 5x3x2 feet which dump to one side by the releasing of a latch on the opposite side. The cars are provided with four cast-iron 12-inch wheels. A car near each end of the train of seven has a brake which is

Train Equipped With Electro-Pneumatic System of Control.

applied by standing on a lever that projects at the end of the car.

A 1-inch cable wound on a 30-inch drum is fastened to the cars and descent is controlled by a hand brake on the drum. Four cars loaded with rock run on a track parallel to the main haulage way. This train of four cars is pulled up by the loaded train running down, and when allowed to descend it pulls up the empty cars. There is a turnout and double track midway of the system where trains pass.

A ½-inch cable is attached to the dummy train. The part of the drum taking the dummy cable is about 24 inches diameter. Cast-iron sheaves with 4-inch face and diameter of 3 feet catch the cable on the curves while wooden rollers 18 inches long and 6 inches diameter are placed along the track to prevent the cable from dragging on the ground. The fall is about 75 feet in a quarter of a mile.

The Recovery of Tin From Scrap Plate.

The tinned iron is placed in a receptacle whose walls consist of a stronger electro-positive metal than tin, e. g., iron. According to a Swedish patent of B. A. Bergmann of Nyfors, this receptacle is filled with caustic alkali and also contains a depolarizer, such as cupric oxide. An electric current results, while at the same time the tin is separated in the form of alkaline stannate. When the alkali lye is saturated with the alkaline stannate, a current of carbonic acid is immediately introduced into the solution. Thereby the tin separates in the form of stannic hydrate. This combination is treated with acid, and from the resultant solution the tin is finally obtained electrolytically in metallic form.—Neueste Erfindungen und Erfahrungen.

THE air resistance to the rotation of a flywheel may cause a considerable loss of energy. A 450 H. P. engine, direct-connected to a generator, has a flywheel with channel-shaped arms. The tests were made by using the generator as a motor, driving the flywheel up to a normal speed. It required 13,300 watts to rotate the wheel and shaft, but by inclosing the arms in a sheet-iron casing the wheel was driven by an expenditure of 9874 watts. The saving effected by use of the shield was 5.7 H. P., or 1.2% of the power of the engine.—Scientific American.

Westinghouse Electro-Pneumatic System of Train Control.

The Brooklyn Elevated Railway Co. has given an order to the Westinghouse Electric & Mfg. Co. for 210 multiple train-control equipments to be used for the operation of electrically propelled trains on its lines. In order to reduce dead weight and to obtain higher tractive effect when starting it is better to place driving motors on the trucks of several of the passenger cars of a train, taking advantage of the weight of the cars, than to put the motors on a locomotive, which must be artificially loaded to give it the necessary adhesion. The company has also purchased 150 equipments which have been in satisfactory operation for nearly a year.

The Westinghouse multiple train-control system, developed by George Westinghouse, it is claimed is well adapted for the operation of trains under everyday conditions. The system involves the use of compressed air for moving the current controlling apparatus, electro-magnetic valves governing the admission of air to the controlling cylinders and low voltage electric circuits running from car to car for controlling the action of the magnetic valves. The connections for the low voltage circuits are the only ones which have to be established between the cars of the

train, no air connections being required outside of the ordinary brake hose. A complete equipment for each motor car consists of two or four electric motors, a controller similar to controllers used on ordinary street cars, and one or two motormen's controlling switches, from any one of which all the car controllers on the train may be operated. The car controller consists of two drums which revolve in bearings, and stationary contact fingers which make contact with points upon the revolving drums. The large, or main drum, opens the main circuit and makes the motor and resistance combinations; the small drum reverses the motors.

The control circuit is isolated from the main power circuit and is not affected by a momentary interruption of current due to ice and sleet on the rails, or other causes. With the low voltage current, grounds and short circuits at the connectors between cars during stormy weather, or fires resulting from high voltage circuits through the train are eliminated. The current for the motors is collected from the third rail, led through the local car-controlling apparatus to the motors and then back to the surface rails and does not pass from car to car. The controlling apparatus is so located that the motorman may have convenient access to all parts from the platform.

All controllers are automatically turned off by the application of the automatic air brakes, and in case of a train breaking in two the brakes are automatically applied and at the same time the power is shut off.

The Brooklyn Elevated will equip all its new cars with four motors each. The 150 cars now in use equipped with the Westinghouse system have each two motors. The trains on the road are made up of five or six cars, two or three of which are usually motor cars. When these trains reach the suburbs they are broken up into smaller units of one or two cars, each containing a motor car, and the smaller trains branch off on different divisions. By this system it is possible to operate cars individually, as on ordinary trolley roads, or to make them up into trains of any length. Also, any proportion of motor cars may be used, making it possible to obtain any desired amount of power for starting the trains quickly, which is necessary in any service involving many stops.

Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 6, 1903.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

OXIDIZING FURNACE.—No. 717,093; J. E. Greenawalt, Denver, Colo.

In stack oxidizing furnace, combination of two or more shaft compartments, dust chamber compartment, means to elevate hot and partially roasted ore falling at bottom of one of shaft compartments, to top of another shaft compartment, and means to collect hot and partially roasted dust falling in dust compartment and elevate it to top of one of shaft compartments.

WELL CASING PACKER.—No. 717,160; J. T. Callanan, Butler, Pa.

Packer comprising tubular packer body having exterior formed with downwardly tapering portion, means for securing body to well casing, and flexible packing material secured to body exterior and inclosing downwardly tapering portion and extending longitudinally beyond lower extremity of body.

PROCESS OF EXTRACTING COPPER FROM ITS ORES.—No. 717,565; A. von Gernet, London, England.

The process of extracting copper from its ore, which consists in slowly passing ore in form of pulp through current of sulphurous acid passed in direction opposite to that of travel of pulp.

WURTZILITE PRODUCT.—No. 716,787; R. M. Thompson, Sutton, Nebr.

The wurtzilite product combined with hardening substance as mica, asbestos or soapstone, and a quantity of sulphur.

EXCAVATING MACHINE.—No. 717,589; E. A. Mathers, Washington, D. C.

In excavating machine, combination of frame, digger comprising head with digging devices and rearwardly projecting arms mounted on frame, arms being mounted to slide in suitable supports on frame, means for carrying digger upward and forward and lowering into earth, and then drawing back toward machine away from point of loading with load and freeing it from load by raising and again carrying forward, and driving mechanism.

CONCENTRATOR.—No. 717,805; J. S. Brownell, San Francisco, Cal.

In vanner or concentrator, including endless traveling belt and worm-gear, members of which are movable one relative to the other and through which motion transmitted, an eccentric from strap of which worm is suspended, and by turning of which worm and gear may become engaged or disengaged, and a swiveled journal-box suspended from strap and in which shaft of worm is mounted.

METHOD OF TREATING ORES.—No. 717,864; J. T. Jones, Iron Mountain, Mich.

Process of mixing with ore, to be treated, leaching fluid, which consists in confining mass of ore in vessel with body of leaching fluid of lesser specific gravity superimposed upon it, carrying portions of ore upward in vessel and releasing it above body of leaching fluid to precipitate it through body, and simultaneously convey portions of leaching fluid below

surface of mass of ore and releasing it and permitting it to rise through same.

EXCAVATOR.—No. 717,835; W. H. Fulcher, Oakland, Cal.

An excavating machine, consisting of portable frame work upon which mechanism is carried, means for advancing it in line of proposed excavation, a transverse extension from one side of frame, an endless chain with excavating mechanism carried thereby, guides for excavating mechanism having one end movably supported from outer end of transverse extension, and mechanism by which inner end of guides and chain sprockets may be raised or depressed.

MINING PUMP.—No. 717,852; J. K. Hogan, Placerville, Cal.

A deep-level pumping apparatus comprising parallel open-bottomed cylinders with inlet openings, plungers, valves and discharge pipe; second series of similar pumps located at intermediate levels between bottom and top; tanks from which pumps are supplied and into which water from levels below is successively delivered; pump rods extending to bottom, rods having connection at lower ends with plungers of lowest pump, and having rackbars at upper ends; mechanism including a horizontal shaft and toothed segments engaging rackbars whereby rods are alternately reciprocated so that one pump is always lifting before the other commences to descend; and connection between rods and plungers of each of intermediate pumps whereby all are operated in unison.

SEPARATOR.—No. 717,971; E. Colvin, Scranton, Pa.

Machine for separating granular material into grades according to size, comprising series of equidistant shafts and series of wheels arranged on each shaft, each wheel consisting of three equidistant radial lifter arms or blades projecting at right angles from shaft, blades of all wheels throughout series being of same length, and corresponding arms or blades of all wheels extending in same direction at all times during revolution, arms or blades of each shaft intermeshing with arms or blades of shafts each side thereof, and number of wheels on shafts being decreased toward discharge end of series of shafts, and

means for imparting motion at same rate of speed to all shafts.

OIL BURNER.—No. 717,937; G. W. Smith, San Jose, Cal.

Oil burner comprising retort having annular flange or projection extending laterally from body thereof, conduits for generated gas extending laterally from lower portion of retort and having upwardly directed apertures, spreader supported upon retort and having wings arranged above apertures and at such a height with reference to flange as to deflect flames from apertures against under side of flange to heat retort.

AUTOMATIC OILER FOR MINING CARS.—No. 718,039; R. S. Walker, Pinehill, Pa.

Wheel having oil chamber extending around but not communicating with bore, waste chamber, oil passage between latter and bore, oil passage between oil chamber and waste chamber, coincident openings in one side of oil chamber and in partition between latter and waste chamber, and closure for openings.

BRIQUETTE MAKING MACHINE.—No. 718,043; E. B. A. Zwayer, Hohoken, N. J.

In briquette molding machine, combination of rolls tangent to each other, disks secured together forming rolls, circumferential ridge on each disk, ridges at right angles to circumferential ridges and in circumferential surfaces of disks, cavities on sides of circumferential ridges and between ridges at right angles thereto, and means for driving rolls.

"Weber" Gasoline Locomotives.

Herewith is illustrated the Weber mine and in-

dustrial locomotive. It is supplied with a scrubber for neutralizing the products of combustion for tunnel work, or with cab for surface work. The frame is of steel. All holes are drilled and reamed and turned drift bolts hold the parts solidly. The engines are of the double-opposed cylinder type, and it is designed to handle the load with ease and least vibration. Both hot tube and electric ignition are used. The engine transmits the power to the drivers by steel cut gearing and the different motions—forward, backward and stops—are controlled by steel clutches operated by levers. The axle boxes are provided with vertical space to allow spring cushions to avoid jar. The drive wheels are steel tired (shrunk on) and are pressed on the axle and keyed.

The Weber system of supplying gasoline to the engine is simple. The locomotive is supplied with a powerful brake, and when a quick stop is necessary both the brake and reverse clutch can be applied.

From the engineer's seat all levers and valves for controlling the locomotive are within reach; he is able to cut out either cylinder from work, thus reducing the consumption of gasoline. The engineer is able to look ahead so that he may see obstructions on the track.

The 4-ton locomotive illustrated in the cut is in operation in a 1200-foot tunnel on the property of the Batopilas Mining Co., at Batopilas, Mexico. This tunnel is almost 2 miles long. The question of vitiating the air by the exhaust gases from the engine, was a serious one. This, the managers say, was overcome by washing these gases in the scrubber shown on the right hand side of the engine.

Experiences of a Working Miner.

Written for the MINING AND SCIENTIFIC PRESS.

Not being overworked, I went out to see my old friend W—, the millman at the B— mill, some months ago. As I approached I did not hear the cheerful roar of the stamps; but W— had told me he expected there would be a shut-down, so I mentally concluded it had arrived. All was quiet about the place—not a soul in sight about the big red mill. I walked up the slope toward the building, hoping to find some one about who could tell me where I might find W—.

As I neared the mill I heard, or thought I heard, a strange noise within. As I drew nearer this peculiar sound grew louder, until at the threshold I hesitated. It sounded like a small cyclone had broken loose within the building. I pushed the sliding door aside, and a glance gave the much desired explanation. W— was there with four assistants "cleaning up." I never saw the process before—conducted in the same way. Three of the assistants—the assayer's helper, the hookkeeper from the office and a mill hand—were vigorously engaged in scraping the unoffending silvered copper plates with hoe-shaped chisels, ground sharp as razors. They were working faithfully and getting down through amalgam and silver to the copper all right. In order to facilitate the process, the assayer had a gasoline blast furnace from the assay office under his arm and was "treating" the plate to a good roasting, while W— followed in his wake with a chisel that fairly peeled from the hot plate the thin coating of amalgam and much silver. It was the final clean-up,

W— explained, as things were "shut down for good."

"We have done this twice before," he further remarked; "it is about the only way we can get anything out of the rock at this mine."

Not long since I met my old friend, Silas Jones, a miner and a careful, conservative man. He owns the O— mine, near P—. I may say that in all probability my old friend would not recognize himself in the above name; but he will, no doubt, should he read the following, recall the conversation. As we met I said:

"Well, Silas, how are you and how is the mine?"

"Oh, I'm all right," said Silas, "and the mine is all right, too, though for a long time it was all wrong."

"Yes," I replied; "I know it was not all roses with you. Where's Pete?"

Pete was his old foreman and, in fact, superintendent, millman and everything else.

"Pete? Oh, he's gone down to Mexico. Got a good job, I guess," replied Silas.

"Pete left you and gone to Mexico?" I inquired, in some surprise, for I knew Pete had been with him for years, and Silas thought there was no one like him.

I thought so, too; but my point of view was somewhat different from that of Silas. I had hinted a number of times to Silas that I thought Pete was rather slow and not wide awake enough for these days; but Silas could not see it. He knew Pete to be perfectly honest, and that he gave freely of all that was in him. But Pete was behind the times.

"Whom have you now?" I asked, interested in knowing what had taken place.

"Oh," said Silas, with a queer smile, "I got a young fellow—regular kid. He's a college boy. I didn't go much on 'em, as you know; but, say, this fellow's all right. He put me to a lot of expense at first—always wanting something new. First he wanted me to put in a huzzaw and what he called an edger. I told him: 'Son, this is a quartz mine, not a sawmill.' But he said he needed it, so I let him have the outfit. Well, you ought to see it work! Cuts off a stick quicker than you can get ready to saw it by hand. And that edger—funny, but I never heard of one before this new fellow came—it's worth its weight in gold. Frames a set while you are thinking about it. You know we had a lot of tanks that used to be used when we worked silver ore from the old H— mine. Well, he has turned that into a cyanide outfit, and he just takes gold out of tailings till further orders. Oh, he is all right, I tell you. Always experimenting and never satisfied till he gets the last cent, or near it. There's one thing about it—the mine pays again—something it has not done before since we got below the water line. He thinks he can make some more improvements and I'm going to give him plenty of head room. He makes mistakes sometimes, but he is making a general success, and that is what counts with me. I tell you, son, Uncle Silas has changed his views some, and I don't believe any more in letting my neighbors do all the experimenting."

Improved Aluminum Methods.

A French engineer by the name of Quesnel has discovered new processes for the manufacture of aluminum which seem to impart to the metal all those qualities which it has heretofore lacked. If the samples submitted have been produced by as simple processes and at about the same cost as aluminum is now manufactured, we have no doubt that the manufacture of this metal will before long undergo a complete revolution.

Mr. Quesnel professes to be able, by insignificant proportions of alloyage—varying from 1 to 20 grams per kilo—to make a whole series of metals offering resistances from 20 to 40 kilos per square millimeter.

This new metal can be chased, stretched and rolled out into plates, leaves and wire; it remains soft like aluminum, or assumes the rigidity of steel plate, without ever breaking, like aluminum, which permits of using it in a thickness three times less, while the solidity is greater.

It can be forged, soldered and brazed. Mr. Quesnel submits some astonishing samples of sheets of 2 meters brazed like angle iron or T bar, which seem impossible to disconnect and which are twisted and pulled sideways.

The homogeneousness of the metal is perfect, without flaws or spongy portions, and it is in no way dry or brittle.—Journal de l'Electrolyse, Paris.

Rocks of similar character pass from one group to another by almost insensible gradations by the addition of certain minerals, which by further additions make them prominent, or, by the gradual disappearance of some mineral, causes the rock to assume a different physical aspect and to also change its chemical composition.

"Weber" Gasoline Locomotive.

Mining Summary.

Specially compiled and reported for the
MINING AND SCIENTIFIC PRESS.

ALASKA.

A strike of gold-bearing quartz is reported on the divide between Chicken and Lost Chicken creeks in Forty Mile district.

ARIZONA.

The copper product of Arizona for 1902 is reported as follows:

	Pounds
Copper Queen, Bisbee.....	36,000,000
United Verde, Jerome.....	35,000,000
Arizona Copper, Clifton.....	32,000,000
Detroit, Morenci.....	17,000,000
Old Dominion, Globe.....	12,000,000
Calumet and Arizona, Bisbee..	3,000,000
Silver Bell, Pima.....	2,600,000
Shannon, Clifton.....	2,000,000
Val Verde, Big Four.....	2,000,000

Total.....141,600,000

COCHISE COUNTY.

A one-fourth interest in the Caballona mine owned by Short & Mead was sold recently for \$50,000 cash. The mine is 15 miles from Douglas, and is shipping seventy-five tons of ore a week.

Work is resumed at the Calumet & Bisbee D. Co., near Bisbee. The property of this company is near the Lake Superior & Pittsburg holdings. S. Turner is superintendent.

GILA COUNTY.

The Troy-Manhattan Co., near Globe, has resumed smelting.

The Old Dominion at Globe is unwatered, the pump at the 1200-foot level is again in operation, and one of the bailing tanks has been replaced by a cage.

MOHAVE COUNTY.

J. Mulligan, owning the Silver mine in the Basin country, near Kingman, says the crosscut has exposed a body of concentrating ore.—S. C. Bagg is making cyanide tests on the tailings from the Katherine ores, recently run through the Sheephall mill.—D. H. Moffatt of Colorado bought the White Hills M. Co.'s property last week at sheriff's sale.

O. P. Posey, manager of the Gold Roads M. Co., is building a cyanide mill at the mine, near Acme. The mill will have a daily capacity of 500 tons. Three hundred men are employed in the mine and at the mill. It is expected to be in operation March 1.

A 40-stamp mill is being erected at the Mellon mine, in the same neighborhood. This property is owned by Mr. Turner of New York.

At the Leland-Mitchell mines of the Mohave M. Co., near Kingman, four tunnels are being driven on the vein. Machine drills are being put in.—Manager Mensch has men at work on the Union Pass mines and a shaft is being sunk in the tunnel, where a 4-foot vein of milling quartz shows. The crosscut tunnel is in 100 feet.—S. C. Bagg of the New Comstock mines says he is drifting on the hanging wall of the Katherine mine at the 185 level and has opened up ore.

SANTA CRUZ COUNTY.

The Old Glory mine in the Oro Blanco district, under the management of Job & Brand, has resumed, with fifteen of the thirty stamps dropping from one of the open cuts. The ore body is 4 feet wide, averaging \$18 per ton. The Oro Blanco group, bonded by J. Owens, is being opened up by three shafts, all of which show ore. A. Bogan is superintendent. The present depth is 80 feet. A hoist is being put in.

YAVAPAI COUNTY.

At the Alto group in Eugene gulch, near Bigbug, the shaft is down 150 feet, but being started from the gulch bottom it has a total depth of 800 feet below the apex. It is intended to sink 50 feet deeper, when the first level will be run.

Platinum is reported found on the Moonlit Wanderer claim, 8 miles east from Prescott, in the vicinity of the White Horse mines, by C. A. Whipple.

The American Copper Co., operating the Iron King mine, near Jerome, are putting in a mill which will treat 100 tons per day.

Superintendent A. J. Pickorell of the Gold & Copper M. & M. Co. says the cyanide plant at the Chicago mill, near Prescott, is in operation.

The Pfau G. M. & R. Co. are working a group of four claims near Jerome, and have a tunnel in 125 feet, showing 3 feet of free milling gold ore.

The United Verde smelter at Jerome is reported temporarily closed down, due to a shortage in coal.

Superintendent Lacase is driving a tun-

nel on the Red Apache mine, Walker district, and is in 155 feet, with 3 feet of ore carrying values in gold, silver and copper.

YUMA COUNTY.

P. Devine, of Devine Bros., at Sunset, is reported to have made a gold strike 9 miles from their camp. The discovery is on the eastern slope of the Harqua Halas, near the top of the divide. Devine has located a number of claims.

CALIFORNIA.

AMADOR COUNTY.

Superintendent B. C. O'Neill of the Del Monte mine, near Jackson, reports as follows: Total length of crosscut tunnel to January 1, 530 feet; cut in December, 68 feet, at a cost of \$9.33 per foot; cost of running mill for December, \$121.50; cost of construction work, \$98.25; total length of Del Monte tunnel to January 1, 173 feet. The upraise will be connected with the old shaft. Drifts will be run east and west.

At the Bunker Hill mine near Amador City the 1400 and 800 levels are being worked. The building of a mill in the spring is proposed, says Superintendent R. C. Downs. It is reported the erection of a 60-stamp mill at the Fremont-Gover near Amador City will begin early in the spring. E. C. Furrington is superintendent.

BUTTE COUNTY.

The Feather River Power Co., incorporated in San Francisco, will install an electric power plant 20 miles above Oroville. Power will be distributed to mines and metallurgical works in that portion of the State and to other industrial enterprises at a distance.

CALAVERAS COUNTY.

(Special Correspondence).—M. A. Shepard has bonded the Shepard mine, 5 miles north of Mountain Ranch, to the Gray Wing Co. The representative will put on a new steam hoist and a 6-stamp mill. Operations will be resumed upon completion of hoist.

Angels, Jan. 13.

(Special Correspondence).—The Sultana M. Co. at Angels is erecting a new gallo-frame and a 20-stamp mill. Work is being pushed and the stamps will begin to drop in February. Twelve Frue vanners will be put in. The construction is in charge of C. Lee. A. Chalmers is superintendent. The Sultana M. Co. are now operating the old Bovee mine.

The Oriole M. Co., near Angels, is changing its compressor from steam to electric power. A 100 H. P. motor is to be put in for the purpose. Work upon the 10-stamp mill is being pushed and will be completed Feb. 1; it will also be run by electricity. A 50 H. P. motor is being put in. While the changing of power from steam to electricity is going on, two ten-hour shifts are developing on the 600 level. There is a large amount of ore blocked out, warranting the erection of the mill. E. D. Griffiths, superintendent, states that they expect to add ten more stamps in the summer.

Angels, Cal., Jan. 14.

In Bear Creek district, near Jenny Lind, the Big Six mine has a shaft down 50 feet and a winze on the ledge 50 feet farther. This winze is run on the hanging wall, and from the bottom a crosscut has been run 12 feet toward the foot wall in ore. The rock carries free gold and sulphurets.

The Carson Hill G. M. Co. has incorporated under Arizona laws. The property of the company consists of the Boston and A. P. A. mines on Carson hill, near Melones, and adjoining the South Carolina on the west.

Work is resumed on the Black Cat mine near Mokelumne Hill. Men are repairing the road leading to the mine.

Work on the Sultana mill near Angels will be completed this month. The tramway from the Bovee shaft to the mill is being torn down and a track laid on the surface.

INYO COUNTY.

The Leidy M. Co. mill, near Bishop, is in operation.

The Cecil R. M. Co. has installed a second battery of five stamps on its property at Ballarat. They propose to put up a cyanide plant.

KERN COUNTY.

The county supervisors have granted a right of way along the county road for a pipe line from the Kern river oil fields to Bakersfield, to be built by W. H. Hart of San Francisco. The line will be double. It is said the intention is to convey oil at a price not exceeding 5 cents a barrel.

The Kern River Oil Co., at McKittrick, will increase the production of their wells to 1500 barrels daily. There are eleven finished wells on the lease.

It is reported that Jewett & Blodgett will build a pipe line from Sunset north-

west to the California Fortune and Lucky Boy wells. Tankage for 175,000 barrels is to be provided at Sunset.

MONO COUNTY.

At the Sweetwater Con. mines in Silverado canyon, near Bridgeport, connection has been made on the lower level with the air shaft.

The Gorilla mine of Lundy has been relocated by S. Lavoroni.

The mining suit of Haggin & Hearst vs. Kelley et al., involving the ownership of the southeast of a group of mines at Bodie, which was tried in the Superior Court at Bridgeport last week, resulted in a verdict for plaintiff. This was the second trial, and the verdict is a reversal of the former decision.

NEVADA COUNTY.

Superintendent Bray is putting in an air compressor at the Posey mine.

At the Union Blue Gravel mine, near North Bloomfield, the 10-stamp mill is in operation. The main tunnel is in 5100 feet.

The Conlin mine, near Grass Valley, has been unwatered and underground operations resumed.

The Crystal Lake G. M. Co.'s 10-stamp mill at Meadow Lake is running on ore that mills \$9 free gold. The vein is 25 feet wide. They propose to put in thirty more stamps this spring.—Freeman & Vineyard of Cisco have bonded their group of Meadow Lake mines to San Francisco parties, who will erect a 10-stamp mill in the spring.

ORANGE COUNTY.

Orange county's oil production from the Fullerton and Brea Canyon districts for December aggregated 120,000 barrels, the largest in the history of the field, and 50% greater than for the same month in 1901. One-third of this was produced by the Santa Fe Railroad Co., which pumps thirty wells. The Brea Canyon Oil Co. is next with 20,000 barrels, while the remainder is divided between a number of smaller companies producing from 2000 to 12,000 barrels apiece. Considerable oil is shipped by the Union Pipe Line to San Pedro, and from there to San Francisco for refining.

PLACER COUNTY.

At the Kings Hill mine, near Iowa Hill, Noble & Carpenter are ground sluicing.—The Dewey hydraulic, at Iowa Hill, is in operation under permit of the Debris Commission.—The Hidden Treasure Co. at Centerville has struck a gravel channel 8500 feet in on the main tunnel. The new channel is 100 feet wide and 21 feet lower than the Hidden Treasure-Mountain Gate channel. An incline has been run and the channel opened 300 feet east and west.—Hosmer & Welker are cleaning up at the Lehigh canyon claim, below the Paragon, at Bath.—The water has been lowered in the Morning Star reservoir, near Damascus, and men are removing 800 dead trees.

The Pine Hill mine, 14 miles from Auburn, has a new 10-stamp mill, two rock breakers, four concentrators and an air compressor. The plant is operated by steam power. The buildings consist of a boarding-house, superintendent's residence, assay office, hoist and mill buildings. Twenty-five men are employed at the mine. The main shaft is 180 feet deep with a 400-foot crosscut and three levels. The vein is 15 feet wide.

PLUMAS COUNTY.

H. B. Budd, J. M. Engle et al. have bought the Borentz, Fallet and Odneal gravel mines at the mouth of Mill creek, above Rich Bar, for \$12,800.

SAN BERNARDINO COUNTY.

The Great Western Oil Co. has filed notices of location covering 16,000 acres near Victor, on the desert north of San Bernardino.

G. H. Hamstadt is working five men on claims near the Copper World.

A body of opal-bearing rock is reported found in the mountains 40 miles north of Barstow.

SAN DIEGO COUNTY.

In a tunnel being run on the Berdugo claim, near Banner, it is reported rich ore has been found.

S. H. Lucas, of Los Angeles, reports that a Boston company has bought the Stonewall gold mine on the Cuyamaca grant, for \$200,000. The mine, which has been idle since 1894, was formerly well equipped with hoist and mill, and has been worked to a depth of 500 feet. It has produced several hundred thousand dollars in the past. S. H. Lucas will be superintendent.

SANTA BARBARA COUNTY.

The Brookshire Co. will be drilling next week.—The Plinal Co. has a second well started.

SHASTA COUNTY.

E. H. Sherk, on his claim at Harrison

Guleb, in digging a cut for the face of a tunnel, is reported to have found gravel from which he panned out coarse gold ranging in value from \$3 to \$12.

A strike of copper ore is reported in the Blue Jay mine, owned by Sutton & Leaming, in the Old Diggings district, 4 miles north of Redding. Samples of the ore show native copper and pyrites. The ledge of copper ore is 2½ feet wide at the surface. The mine is within 2½ miles of the Keswick smelter.

The Great Divide G. Co., composed of St. Louis, Mo., and Redding men, has bought two groups of gold and copper claims in the Mule Town Mountain mining district, 4 miles west of Redding. The mine joins the Mount Shasta mine on the south.

The Crown Deep M. Co. will put up a cyanide plant on its claims, 4 miles west of Redding, at a cost of \$75,000, says the Free Press. The group comprises five claims. The plant will be on the Gold Bronze claim.

The final payment has been made on the \$650,000 bond on the Balaklava copper claims, 6 miles north of Keswick, by the Western Exploration Co. W. F. Snyder is manager.

SHASTA COUNTY.

At the Connor group of mines on Salt creek, 4 miles west of Redding, the vein has been out at 80 feet in the shaft.

SIERRA COUNTY.

A. C. Busch says he will reopen his Phoenix mine, near Sierra City, this spring.

R. Phelan says he has bought the interests of some of his partners in the Sacred Mound mine, near Downville, and he intends to drive the Sacred Mound tunnel to intercept the ledge of the Butte Saddle mine, which would give 2500 feet of ore backs.

SISKIYOU COUNTY.

A crosscut tunnel, now in over 1300 feet, is being driven with machine drills at the Cherry Hill mine, near Yreka, to cut the vein developed in the upper workings. H. W. Turner is superintendent and E. H. Nutter foreman of the mine.

The Etna Advance says a strike has been made in the Advance mine at Salmon river, on Russian creek. The ledge is 4 feet thick at a depth of 75 feet.

The Yreka M. & M. Co., owning the Ball group in Klamath basin, Liberty district, have their aerial tramway in operation. Superintendent L. D. Ball has let several contracts for development work and is opening up ore bodies in the Klamath ledge. It is the intention to install an electric plant on the Salmon river.

TUOLUMNE COUNTY.

The Rawhide M. Co. has attached the property of the Tuolumne County Water & Power Co.

J. N. Jones has sold to A. Clark, S. Y. Strait and E. F. Cadle of Stockton a three-fourths interest in the Izurnia Irene mine, adjoining the Maddox ranch, 1½ mile from Confidence.

W. J. Graham has sold to the Vetalis M. & M. Co. a portion of the May Flower group of mines, near Carters, also the right of way through the tunnel for twenty years.

W. H. McClintock has deeded to the Don Pedro G. M. Co. the Don Pedro and Stokes quartz mines and the Stokes mill-site, near Don Pedro.

At the Dutch mine at Quartz the main shaft has passed the 1500-foot mark and they are sinking.

At the Harvard mine, near Jamestown, thirty of the sixty stamps are dropping on ore from Nos. 1 and 2 shafts, both down 700 feet, electric and steam power being used.

Superintendent E. Partz of the Goldwin mine, near Carters, says operations will be resumed.—At the Spring Gulch Superintendent Parrish has the 6-stamp mill in operation.—The mill at the Sunnyside has resumed, says Superintendent Smith.—At the Top Notch, near Carters, work has been temporarily stopped on account of water. Manager W. R. Cunningham says a steam hoist and pump will be placed.—A stream running 10 inches of water was tapped in the Lady Washington tunnel, near Carters, last week.—The ledge at the Esmeralda has been struck.—The Lost Fox mill has closed temporarily while the shaft is being sunk.

A road is to be built near Carters to the Jersey Blue mine in the canyon near the Goldwin by Superintendent Tyack.—An oil burning plant has been installed at the Black Oak, near Soulsbyville.—The Rio Vista M. Co. has filed with the county clerk notice of its change of place of business from Columbia to Sonora.—Work will be resumed on the Black Oak south extension, known as the Sullivan.—A cleanup at the Prudhomme mill on January 1 is said to have given \$900 for a nine days' run.

It is reported work will be resumed in

the Santa Ysabel mines at Stent. E. C. Loftus is superintendent.

At the Big Casino, near Big Oak Flat, they have laid a pipe from the mill to the creek, where they are putting in a dam. A gasoline engine and pump are in operation. Underground they are working the 400 level east of the Mack shaft. As soon as the compressor is ready, sinking will resume in the Wooten shaft and a drift run west to connect with the older works. It is proposed to add ten stamps to the mill.

At the Two Brothers, operated by the Big Casino Co., near Big Oak Flat, sinking is resumed.

Operations are resumed at the Hull mine, near Groveland, with W. Vincent superintendent.

The Laura, North Star, Carlotta, Pennsylvania, Brown, Venus, Columbus and Columbus Extension mines, near Carters, are reported sold to Eastern men. Three of these mines have hoists, mills, etc. T. M. Wells is general manager and C. L. Lang superintendent.

COLORADO.

BOULDER COUNTY.

The mill of the Gold Extraction Co. at Wall Street has resumed. The mill is equipped to treat ore by an electrolytic process. There are 1000 tons from the Nancy tunnel and several thousand tons from other mines on hand to be treated by the new process.

The South American mine, near Wall Street, is being worked by leasers. Manager Tiffany says the Tambourine will resume. Machine drills are at work in the Nancy tunnel. The George Henry claim, worked through the Black Cloud tunnel, is showing an 18-inch streak that runs \$36.

A contract has been let to drive a tunnel 3300 feet to cut the Melvina vein by Manager J. R. Wolff of the Melvina mine at Wall Street. It will be 5x7½ and starts on the Little Melvina. Machinery is to be installed.

The Savannah Coal, Oil & Gas Co. last week made its last payment of \$9075 on the G. R. Poor farm, northeast of Boulder. There are thirty three acres in this tract, which is south of the Otero property.

The Corona M. Co., through Manager B. A. Langridge, has made a second payment on the purchase price of \$100,000 for the Black Cloud group, Gold Hill district.

In the Boulder-Valmont well, at Boulder, the drill has cut through 45 feet of oil sand of a white pebbly nature and oil has risen 800 feet in the hole. The Boulder-Valmont is 200 yards north of the Savannah and surrounded by the three Otero wells. At 1960 feet the drill was still in sand.

The Mountain Chief property, near Rowena, has been taken under lease and bond by E. Martin.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Whittier group of mines at Fall River has been sold to the Lucania M. T. & T. Co. of Colorado Springs for \$2000. The Lucania Co. intend driving a tunnel through to Russell gulch. The tunnel is now in 400 feet. The tunnel on the Whittier claim is in 200 feet; ore averages \$10. They will install an air compressor.

Fall River, Jan. 12.

The Idaho Springs Gazette gives the following figures, showing the increase of output for this county:

Year.	Cars.	Tons.
1899.....	924.....	18,480
1900.....	1,012.....	20,230
1901.....	1,410.....	28,200
1902.....	1,677.....	33,540

Driving by hand in the Lucania tunnel, near Idaho Springs, is stopped and the foundations for a power plant are being put in.

A strike is reported at the Little Matie, near Empire, in ground worked by leasers.

Leases on the Silver Mountain group have been granted to Trevillion & Co., Wellbaum, Needham, and others. The workings consist of a shaft 350 feet deep and four levels that connect with the Pittsburg lode.

Lessee Rich of Denver, working the Mendota dumps, near Georgetown, is shipping the zinc ore to the Empire Zinc Co.

Manager Teagarden, the Red Oak Co., near Georgetown, has resumed on the crosscut from the Scepter adit to tap the Astor vein and expects to drive 75 feet. The Scepter adit will be driven ahead, and a raise of 396 feet made to connect with lower adit on the Sunhurst. The tramway will be repaired. Electric wires are being run to the Scepter adit to operate a fan, and electric drills will be used.

The Beresford M. & M. Co. has bought a group of claims opposite the Lamartine mine in Freeland district, consisting of forty acres, and a 3000-foot tunnel site. R. Willis of Colorado Springs is manager.

The shipments of ore of all grades from the mines of Empire for 1902 amounted to 3000 tons. The average value is estimated at \$20 per ton. This is net to the miner who shipped the ore; 85% of this was gold. Silver, lead and copper made up the balance.

FREMONT COUNTY.

(Special Correspondence).—"Positively No Admittance; Apply at Office!" "Keep Out. This Means You!" and other stereotyped signs with which one is usually confronted are done away with at the works of the United States Smelting & Refining Co., Canon City. They have no secret process to conceal. The chief product is pigma, or paint base. They are handling about 100 tons of ore per day. They are more than doubling the capacity of the plant. All of the improvements are going on while the plant is in operation. They are erecting a new sampling mill. One hundred men are employed. D. C. Jackling is manager.

The Dorcas mill, at Florence, is handling 125 tons of ore daily from the Cripple Creek district. Begeer's cyanide process is in use in the mill. The capacity of the mill is being added to.

The Frszer Oil & Gas Co., Florence, has a lease on sixty acres of ground in the oil belt; they commenced operations Oct. 1, 1902, and started to pumping on Dec. 9. They have a good flow of oil. No. 1 is down 2000 feet and they are starting to drill No. 2. Derricks are of the standard type, 72 feet in height. G. Columbia is manager.

Florence, Jan. 13.

The Fremont M. & D. Co. has been incorporated in Florence to operate in Fremont, Teller and Hinsdale counties.

G. Heberling and M. Crowner have a contract for drilling for oil in the South Park field. The United Oil Co. and other companies are arranging to put down wells there, says Superintendent Robinson.

A 100-ton addition will be built to the Empire smelter, near Canon City. Zinc and lead ores only are treated. A 50 H. P. motor is on the ground to be used for reserve purposes.

GILPIN COUNTY.

A number of leasers are at work on properties of the Hillsdale G. M. Co., in Gregory district, and regular shipments are made to the mill.

The Forfar mine on Pewabic mountain, near Central City, has resumed under lease and bond by E. S. Moulton. The shaft, which is 300 feet deep, is being unwatered.

The Druid G. M. Co. are working the Hazeltine property in Willis gulch. They are drifting and crosscutting on the 100-foot level of the shaft, west of the main shaft, before resuming sinking. They have put up a hoist on a south shaft. C. W. Anderson is superintendent.

Russell gulch parties are operating the Frontenac at the head of South Willis gulch, under a lease from Kruse, Campbell & Co., and making regular shipments to the smelter.

Sinking is resumed at the Powers shaft in Russell district, a dam having been completed to catch the water at the 200 level, and will be sunk to the 325-foot point. The 200-foot levels are showing up ore with a shoot 18 inches wide of enargite. The last shipments made from this level gave net values of \$75 per ton, with 23% copper.

F. Frickey has a contract for sinking 25 feet on the Old Ann mine, at the head of Silver creek, which will make it 425 feet deep, after which drifting and crosscutting will begin.—Central City parties, working the Baby Ruth mine, in Eureka district, made shipments last week to the stamp mills.

Sinking is resumed at the Bon Ton mine in Eureka district, operated by the Cleveland M. Co., and will go down to 250 feet.

At the Spur Daisy two shifts are re-timbering the shaft and are down 200 feet. When finished, sinking will resume from the 260-foot level. The ore is high grade.

Central City parties are operating the Ingeborg mine, on Winnebago hill, and have their shaft down 300 feet. Drifts have been started. An upraise is being made from the west 170 level. Shipments of ore from the 300 level are being made.

Shipments were made last week from the Hampton mine, in lower Russell gulch, to the Golden smelter.—Central City men are working on the 600 level of the Cour d'Alene, on Academy hill, under a lease and bond.

New England owners of the Nehema and Cotton properties on Bobtail hill, near Central City, will enlarge their hoisting plant. Sinking is being carried on in the Nehema extension.

The Fairfield shaft, near Russell gulch, is down 500 feet and a level started at that point. W. M. Nickerson of Denver is manager.

GUNNISON COUNTY.

The Pitkin Gold Belt M. Co. has opened

ore in the 235-foot level of the Whig shaft which averages \$40 per ton.

At the coal mines at Somerset, in the western part of the county, the Denver & Rio Grande Co. are erecting coal sheds and bunkers.

A 6-foot body of \$50 ore has been opened in the shaft of the Citizen mine at Pitkin. The company is placing machinery over the shaft, which is down 100 feet. The Maid of Athens, adjoining, has a similar body of ore and is shipping.

The Farley group in the Gold Brick district has been sold for \$5000 on a bond given last fall. Ore shipments from the Granite Mountain mine in Jones gulch are giving values of \$75 per ton in gold.

JEFFERSON COUNTY.

Last week the top works of the Cross coal mine, 1 mile south of Golden, were destroyed by fire. W. Prout, superintendent, says the loss is \$4000, with no insurance.

LAKE COUNTY.

The following are the tonnage figures for Leadville district for 1902: Carbonate ores, 22,930 tons; oxidized iron, 285,494 tons; sulphide, 281,558 tons; zinc, 85,699 tons; siliceous, 72,215 tons; manganese oxide, 1050; total, 748,746.

The men employed in Leadville district: Miners.....2,278
Smelter men.....1,000
Teaming.....187
Miscellaneous.....1,021

Total.....4,486

J. P. LaBelle of the LaBelle M. Co., Leadville, has arranged for the resumption of work on the Black Prince on Breece hill.

The Valentine workings are unwatered below the 500-foot level and work has begun at that station and a pump placed which will handle 1000 gallons of water per minute. No further trouble from water is anticipated. The Valentine will be shipping in a short time.

It is reported that Nicholson & Rodman have leased the Coronado mine at Leadville and they will work it in connection with the Midas. The Coronado has bodies of iron that can be sold to the smelters and it has a shaft deeper than the Midas. They will drive under the Midas shaft and connect. The Oolyte M. Co. has completed the shaft house and sinking is begun.

Work has begun on remodeling and rebuilding of the pyritic smelter at Leadville by the Republic S. & R. Co., recently incorporated. T. Goodwin, general manager, says that the three furnaces would be enlarged and \$75,000 expended in improvements. The plant will handle 500 tons of ore a day. The matte will be sent to the smelter at Salida for treatment. The company owns the New Monarch group at Leadville and will handle several hundred tons a day of its own ore.

W. E. Musgrove says he will this spring work the body of tripoli on his ranch, near Leadville. The deposit is 1 to 4 feet thick and 200 feet in length.

The lessees on the Castle View property on Carbonate hill, Leadville, after taking out a quantity of low-grade iron ore have opened up a body of high-grade lead ore, from which shipments are being made. Lessees of the Sunday mine on Breece hill are developing from the 375-foot shaft.

MESA COUNTY.

A pyritic smelter of 400 tons daily capacity is being built at Grand Junction, and is expected to be ready for operation March 1.

MINERAL COUNTY.

The Candle says the tonnage output of Creede district is given in the following table, at least one-third of this output being concentrates, a product of five to one:

Months.	Cars.	Tons.
January.....	291.....	4,803
February.....	256.....	4,563
March.....	281.....	4,710
April.....	275.....	4,778
May.....	267.....	4,593
June.....	384.....	6,475
July.....	361.....	6,596
August.....	377.....	7,003
September.....	347.....	7,079
October.....	366.....	7,719
November.....	337.....	7,362
December.....	182.....	5,512
Total.....	3,724.....	71,193

PITKIN COUNTY.

It is reported the Della S. mill near Aspen will resume in a short time, having been leased to crush Bushwhacker ore.

The Belzora-Bassick has resumed operations in their 800-foot tunnel, near Pitkin. This company owns the D. C. group adjoining the Bassick. They expect to do considerable work during the season. They also intend to resume at the Little Charley, on which they hold a lease.

SAGUACHE COUNTY.

The Maple Leaf, near Cochetopa, is being operated by Gunnison parties and is shipping ore that will average \$60.

SAN JUAN COUNTY.

Men employed by mines of San Juan county in 1902: Silver Lake, mine and mill, 285; Gold King, mine and mill, 265; Sunnyside, mine and mill, 100; Silver Lodge, mine and mill, 85; Mogul mine, 50; Highland Mary, 50; Esmeralda, 50; North Star, Sultan Mt., 25; Eureka Exploration Co., 20; Natalie, 22; Henrietta, 20; Green Mountain Co., 15; Big Colorado Co., 15; Hercules Consolidated Co., 10; Notaway-Champion, 10; Royal M. Co., 40. Little Bessie, 12; other properties, including prospects, 250; total, 1324.

The shipments for 1902 amounted to 48,160 tons, of which four-fifths were concentrates, distributed as follows:

Gold King (concentrates), 14,428 tons.....	\$750,250
Silver Lake (concentrates), 13,350 tons.....	600,000
Sunnyside (concentrates), 4,742 tons.....	199,164
All other mines and mills, viz: Esmeralda, Red Mountain district, Eureka district, Contention, Brooklyn, Notaway, North Star, Royal, Emma, Nelgold, Cement Creek district, etc., 15,640 tons (principally crude).....	828,920
Amalgam and bullion from mills	564,836
Smelter matte freighted and gold ore expressed.....	105,000
Total.....	\$3,048,170

SAN MIGUEL COUNTY.

Eighty stamps of the Pandora mill of the Smuggler-Union Co. are dropping, crushing 200 to 235 tons of ore daily. The Contention will furnish one-third and the balance comes from the Bullion tunnel level of the Smuggler. One hundred miners are employed at the Smuggler.

SUMMIT COUNTY.

At the Jemima mine on Glacier mountain, near Montezuma, they have driven 75 feet on the cross vein, which widened from 2 inches to 12 feet, with irregular bunches assaying 100 ounces in silver and 36% lead. It is expected to cut the Teller lode. A new company began operations on the Little Jumbo property last week. They have a vein 8 feet wide assaying \$5 in gold, forty-five ounces in silver and 30% lead. Work is being done on the Tip Top, south of the Little Jumbo. This property shows values in lead, gold and silver. The Silver King tramway is in operation. Drifts both ways from the shaft on the lower level of the Pennsylvania mine are being driven and stoping is begun on this level. The 2000-foot contracts on the Rothschild tunnel are completed and the company is calling for bids for 2000 feet more.

The Jessie mine and mill in Gold Run is reported sold to an English company last week.

TELLER COUNTY.

The December production from the Raaler mine of the C. K. & N. Co., Cripple Creek district, amounted to 690 tons of ore that averaged \$50 per ton. A station is being cut at 375 feet, after which sinking will be resumed. The production last month came from the 300 level.—The lessees operating the Cardinal claim of the Little Valeria are driving a tunnel in the north end of the property which will connect with the shaft at a depth of 200 feet, which will permit taking the ore out in the gulch instead of hoisting it to surface on the top of the hill.—The War Eagle Leasing Co., operating the War Eagle on Bull hill, have increased their shipments to 250 tons per week.

The lease on the Fluorine and Fort Wilcox property on Copper mountain, Cripple Creek district, has been bought by the Sioux Falls & Cripple Creek G. M. & D. Co. It is the intention to erect a cyanide plant of 100 tons daily capacity, and work on the excavations for the foundations has begun. The contract for the mill has been let, which will be erected on the J. F. H. claim of the Amethyst Co. Underground work is in progress at three different points, the principal one being in the Fort Wilcox tunnel, which is intended to cut the Fluorine at a depth of 320 feet.

On the lease granted on the south end of the Granite on Battle mountain, near Cripple Creek, to Cartwright & Co., ore is being broken in the 60-foot and the 150-foot levels; a steam hoisting and compressor plant is in operation. The lease takes in that portion of the property around the Midland Terminal tracks. The shaft is 160 feet deep.

The Stratton Independence Co., Limited, on the 12th inst. filed in the United States Court a suit for \$6,000,000 against the executors and trustees of the Stratton

estate and also against I. H. Stratton, heir at law. The complaint alleges that, at the time the mine was sampled, preparatory to concluding the sale, which had been negotiated through the Venture Corporation of London, the samples were "salted" so that the amount of ore estimated on those samples was valued at \$7,000,000, when, in reality, the ore in sight was worth only \$2,000,000 or less. It is alleged that the sacks of samples were opened and sprinkled with ground-up sylvanite.

The Venture Corporation will file a similar suit, claiming that its expert, T. A. Rlokard, was deceived by the salted ore, and the individual stockholders will bring actions for the return of their money, alleging that they were induced to purchase stock at \$5, \$10 and \$15, which was not worth such prices.

Superintendent C. B. Burch has resumed work on the Little John group in Pony gulch, Cripple Creek district. The shaft, down 100 feet, will be sunk an additional 500 feet, and from that point a crosscut driven both ways. Lessees on the Central claim on Gold hill have started a tunnel from the gulch on the north side to cut the main workings at depth. Lessees Gilbert & Co., working on the south end of the Sheriff claim on Raven hill, got returns from their initial shipment of ten tons sent last week of \$25 to the ton.

The December production from the Raalor mine, of the C. K. & N. Co., Cripple Creek district, amounted to 600 tons of ore averaging \$50, which came from the 300-foot level. The shaft is down 375 feet, and a station is being cut at that point.

Lessees Sharp and others, working on the Uncle Sam claim of the Blanche Co. on Bull hill, Cripple Creek, made a shipment of \$25 ore from the 300-foot level last week.

The directors of the Ben Hur G. M. Co., Cripple Creek district, have decided to grant several one-year leases on its property. The Little King and Queen claim will be leased in blocks down to the level of the Good Will tunnel, crossing the property at a depth of 410 feet. C. Tillery has a hock on the north end of the claim and B. F. Tipton will get the Hanson shaft.

Lessees Smith & Altman, operating on the Elizabeth Cooper claim of the Doctor Jack Pot Co., have made a shipment of thirty-three tons, which gave the company royalties amounting to \$905.85. One lot of 17.94 tons was settled for at 4.30 ounces gold per ton; 1470 pounds at 20.73 ounces gold and 5.01 ounces silver; a third lot of 15.959 tons at 7.10 ounces gold and 3.52 ounces silver.

The McFarland & Owenby Co., operating on the Pharmacist Acacia, Isabella and other properties at Cripple Creek, has reorganized as the Owenby Leasing Co., with F. D. French as general manager and W. Campbell as superintendent. The Rocky Mountain Co., operating the south end of the Delmonico, sent out a car of \$50 ore last week, and are sinking the main shaft to 350 feet. From this point levels will be run to the ore shoot. The Practical Leasing Co., operating the Trachyte, sent out 800 tons of ore during December, which returned an average of \$40 to the ton. Sinking on the Findley has ceased, as the shaft is down 1475 feet, and levels are being driven both ways on the vein. A level is started at the 100-foot point to explore the Mountain Beauty ground.

G. Johnson and associates, operating a block on the Pharmacist, Cripple Creek district, sent out a thirty-ton shipment of ore last week assaying \$40. The McDade lease on the same property sent out two carloads. Decker, Patten & Co., leasing on the Gold Sovereign, began shipping last week. Work is resumed on the Amanda property at Windy Point. At the Golden Cycle the shaft is being sunk to 1100 feet. The Last Dollar shipped twenty-five carloads of ore last week.

A new pump with capacity of 1000 gallons a minute to a height of 1000 feet, is being set up in the 1400-foot level of Stratton's Independence on Battle mountain. Manager T. Cornish has had the drifts and crosscuts in the lower levels bulkheaded. The mine produces 250 tons a day. The ore is sorted and shows an increase in average value.

Owenby & Co., operating the lease on the north end of the Burns claims of the Acacia, Cripple Creek district, have granted a sub-lease to Toole & Needham on the workings formerly operated by Fitch & Co.—Gray & Kurtz, leasing on the Monument, shipped a total of 165 carloads of ore last year. Each car contained thirty tons, assaying \$38 gold. The lessees have put in another compressor and are adding more machine drills.—At the Carbonate Queen claim of the Ophir Co., on the northwest slope of Battle mountain, above the Sunset-Eclipse mine, they have erected ore bins and will begin shipments. On the other side of the

mountain they are sinking the shaft, now down 725 feet. It is the intention to continue sinking to 1000 feet.

From the Mary McKinney mine, Cripple Creek district, during December were shipped by the company ninety cars of ore, of which seventy cars went to the smelters and twenty to the mills, a total of 2250 tons, valued at \$75,000. Lessees shipped 250 tons. When the drainage tunnel is completed the company will run a level at the 600-foot point.—The west end of the Mohican property, on Squaw mountain, is under lease to D. McFee, who has a shaft down 30 feet and is drifting on the vein.—Manager W. F. Littell of the Big Twenty Co. will put in a 180 H. P. boiler and a three-drill compressor.

The treasurer's report of the Findley G. M. Co., Cripple Creek district, says during 1902 the shaft was sunk to a depth of 1400 feet and levels run to and on the vein of 900 feet, 1000 feet and 1200 feet. Crosscuts to the vein at 1500 and 1400 feet will be driven as soon as the water conditions permit. There are no leases on the property.

C. Tillery, leasing on the Ben Hur, says in sinking on the King claim at a depth of 45 feet he cut a vein of 18 inches pay quartz.

IDAHO.

IDAHO COUNTY.

The Jumbo M. Co. at Buffalo Hump has struck the ledge in the lower tunnel and has drifted 190 feet on it. The ore is 10 feet wide and averages \$10. The tunnel has 400 feet yet to run to reach a point under the shoot in the upper tunnel.—The Crackerjack, with five stamps, is mining and milling 8 feet of ore. The owners will start to drive their lower tunnel next week.

KOOTENAI COUNTY.

Manager J. W. Ferguson of the Mexleo, near Sandpoint on Lake Pend d'Oreille, says he has the tunnel in 450 feet, reaching 200 feet on the lead. The vein is 4 feet wide, with a paystreak of 6 inches. They are on the Black Tall mountain, 1000 feet from the lake, and can land ore at the smelter to be built at Sandpoint for \$1 per ton.

The Panhandle S. & R. Co. has bought 400 acres of land at Sand Point as a site for the smelter that the company intends to construct. They propose a 300-ton smelter and have bought a line of three steamboats on Lake Pen d'Oreille and the Venezuela group of mining claims.

LATAH COUNTY.

F. C. Smith, working the White Cross mine on Moscow mountain, 9 miles northeast of Moscow, reports a run of twenty tons through the mill, giving a return of \$25 in gold per ton. The ore came from the 225-foot level in an inclined shaft, where ledge is 3½ feet wide. Work in the shaft has been retarded by water and pumps will be put in.

OWYHEE COUNTY.

The Alta Vista M. Co., near Silver City, will install an electric drill.—The Adde mill is making a test run on fifty tons of ore from the Whiskey property.—Operations are resumed at the Sinker tunnel.

SHOSHONE COUNTY.

Eight inches of galena are reported struck in the tunnel of the Humming Bird, near Burke, at 1140 feet from the mouth.

It is said that from 350 to 500 more men are at work in the Cœur d'Alene mines now than at this time last year. It is estimated that 3000 men are working. At Wardner mines, 1000; up Canyon creek—Tiger-Poorman, 60; Mammoth, 140; Hecla, 100; Standard, 245; and Frisco, 250; at Mullan—Morning, 250; and Hunter, 50; at California, up Nine Mile, 45; at sampler below Wallace, 35; at mines at Murray and prospects, 400; at Hercules, 50. Minimum wages in the Cœur d'Alenes are \$3.50 underground, except at Wardner, where it is \$3.50 and \$3; day shift is ten hours and night shift nine.

The North American G. M. Co. is incorporated; C. S. Cryslar, B. M. Cryslar, J. M. Savage, G. H. Stephenson, J. F. Griffin, to operate placer mines near Delta.

The Standard M. Co. near Wallace are putting in electric pumps on the 1000-foot level at a cost of \$30,000. They have a capacity of 500 gallons per minute. The Standard Co. will also use electricity for the compressor. Twenty-six drills are in operation.

The Snow Storm M. Co., near Mullan, is putting in a 2-drill compressor at No. 3 tunnel, to be run by water power. It is expected to complete the tunnel by July 1.

The Ranger tunnel on the Wyoming cut the foot wall of the vein last week. The tunnel is in 2125 feet.

The Atlas M. Co., operating claims on Stevens peak, near Wallace, has let a contract to drive the tunnel 500 feet. Three hundred and fifty feet of work has been

done on the property. The lead was cut by a crosscut tunnel.

WASHINGTON COUNTY.

W. T. Getty, superintendent of the Con. Copper Co. at Mineral, says the compressor is on the ground and he expects to have the smelters in operation Feb. 15th.

KANSAS.

ALLAN COUNTY.

The Standard Oil Co. has completed its 28-mile pipeline connecting the field at Iola with refinery at Neosho. One year ago there was not to exceed twenty wells in the field, now there are 200. The Neosho Valley Oil, Gas and Mineral Co. completed their No. 16 last week. They finished cleaning and shot their No. 13 on the same date.

NEOSHO COUNTY.

There are forty drilling rigs in operation in the oil fields of southeastern Kansas. The McKinley Oil & Gas Co. completed its well No. 5 last week and shot it with forty quarts of nitroglycerine.—G. Z. Work has shot his well No. 4.—The Kansas Crude Oil Co. has brought in No. 13 on the Mann lease.—The Chanute Crude Oil Co. brought in No. 8, on the Haum farm, recently.—Mr. O'Neill brought in a gasser on the Morrison farm, west of Chanute.—The Commonwealth Oil Co. of Taylorville Ill., has completed its second well on its lease adjoining the Keystone property.—The American Oil Co. brought in No. 6 recently.

LOUISIANA.

CALCASIEU COUNTY.

W. R. Childs and S. M. Scott of the Central Oil Refining Co. have arranged to build an oil refinery at Welsh on the Southern Pacific Railroad, to have a daily capacity of 500 barrels.

MICHIGAN.

HOUGHTON COUNTY.

It is said the 6-head Hecla mill, which the Calumet & Hecla M. Co. is building as an addition to the Lake Linden plant, will operate with 40% of the water ordinarily required for the amount of rock treated. All waste sand from the Calumet & Hecla plant will be elevated by a 65-foot sand wheel, from the top of which it will be discharged through launders into the lake.

The decrease of 1,290,720 pounds in the copper output of the Quincy mine, near Houghton, as compared with the product for the previous year, was due to decrease in copper contents of rock, which have decreased from twenty-three pounds per ton to twenty pounds. The cost of production in 1901 was 8½ cents per pound; the cost last year was less.

The Wolverine mine, near Houghton, produced for 1902 6,150,000 pounds of refined copper.

The December product of the Mohawk, at Houghton, one head running nineteen days, amounted to 150 tons 1300 pounds, being equal to thirty-five pounds of metal to the ton of rock stamped.

It is difficult to determine the value of the copper production of the Lake district in 1902. Most of the Lake mines sell direct to consumers, sometimes under the market price and sometimes at a slight advance. Estimating the market value of the 1902 production at the current selling price for the year, the Lake Superior output was worth \$19,500,000. Dividends from this production amounted to 12% of the gross value. To date the Lake mines have produced 3,002,679 867 pounds of fine copper, which sold for \$461,117,304. The dividend disbursements of Lake Superior mining companies to the close of 1902 have been as follows: Atlantic, \$940,000; Calumet & Hecla, \$79,850,000; Central, \$1,970,000; Cliff, \$33,518,620; Copper Falls, \$100,000; Franklin, \$1,240,000; Minnesota, \$1,820,000; National, \$320,000; Osceola, \$4,407,000; Pewabic, \$1,000,000; Tamarack, \$3,490,000; Wolverine, \$990,000; Phoenix, \$20,000; Quincy, \$13,570,000; Ridge, \$100,000; total, \$117,335,620. The Calumet & Hecla has furnished 68%, the Quincy 11% and the Tamarack 7% of the total profits returned to shareholders. In 1902 the total dividend disbursements of Lake Superior copper mines was \$3,440,000, compared with \$7,496,000 during the previous year, the decline in the price of copper being the cause. The profits in 1902 were much larger than the amounts distributed to shareholders, but the surplus funds were largely added to, notably in the case of the Calumet & Hecla.

MINNESOTA.

SAINT LOUIS COUNTY.

The Cleveland Cliffs Iron M. Co. has made a find of iron ore on the Western Mesaba range, where a body of high-grade ore has been found. The option for the lease covers eighty acres. The com-

pany claims the mine shows up 2,000,000 tons of ore, which runs 58% to 60% iron and is low in phosphorus. The property has a depth of 115 feet in ore.

MONTANA.

CASCADE COUNTY.

The Conrads of Great Falls are reported to have bought 600 acres of coal lands at Belt, adjoining the properties of the Anacoda Co., for \$35,000.

SILVER BOW COUNTY.

Suits in which damages aggregate \$134,500 have been filed in the United States court against the four principal smelting companies at Butte because of alleged pollution of the waters of Silver Bow creek by tailings from the smelters.

MISSOULA COUNTY.

The Bitter Root Copper M. Co., composed of Minnesota men, propose to erect a \$500,000 smelter, but are asking for a subsidy in the way of a site. Manager W. Q. Ranft in Butte says the Bitter Root C. M. Co. owns a group of claims near St. Regis, among which are the Richmond and Monitor mines, both yielding copper and gold.

NEVADA.

ELKO COUNTY.

At White Rock the Edgemont Co. is employing forty-five men and has its 20-stamp mill in operation. Thirty men are employed in the Curious mine and ten stamps are dropping there. The Riddle mine has been bonded by Eastern men for \$100,000.

HUMBOLDT COUNTY.

(Special Correspondence)—C. S. Vadner, of Salt Lake City, Utah, has closed a deal for the transfer of twenty claims in the Kennedy mining district, owned by Mr. Vadner and the Blossom estate, for \$70,000. In November, 1902, Mr. Vadner interested a Philadelphia company, headed by W. Cramp, of the shipbuilding firm of Cramp & Sons, with J. W. Grange, S. B. Stinson and G. P. Schober in his mines. Mr. Vadner is retained as superintendent. The company will put in a complete plant. The high grade ores will be shipped to Salt Lake and the low grade ores reduced at the mines. Twelve men are at work. The number will be increased to fifty.

Winnemucca, Nev., Jan. 12.

The California-Nevada M. Co., driving their Victor tunnel, expect to cut the vein next week. A 100-ton mill will be erected near the tunnel and a 40-ton mill at the Arizona mine, at Unionville.

The company owning the nitre deposits near Lovelock has been reorganized.

LINCOLN COUNTY.

Near Searchlight, R. Bowman has finished his contract of sinking 65 feet in the shaft on the Encinitas. The books of the deputy recorder of the district show a total of fifty-two entries during the month of December.

Work is resumed in the mines of the Quartette Co. at Searchlight and drifting is being done on the 600 level. The station at the 600 level is completed and a 26,000 gallon tank is being put in. The mill at the river will be started as soon as the bins can be filled.

LYON COUNTY.

Gypsum from the deposit at Mound House is being used in Reno for the manufacture of plaster.

NYE COUNTY.

On the Tonopah Fraction, near Butler, the hoisting plant of shaft No. 1 has been removed to shaft No. 5, and sinking the latter to a depth of 550 feet begun. From here connection will be made with the 400 level of the three-compartment No. 2 shaft.

The O'Meara-Lynch Co. is taking out ore running \$150 to the ton, at the Alpine group on Lone mountain.

STOREY COUNTY.

At the Brunswick lode, near Virginia City, they have completed enlarging drill hole No. 3 to receive the 7-inch casing, and drilling is resumed.

WASHOE COUNTY.

The Galena Hill G. & S. M. Co., owning the Shannon group, 2 miles from Steamboat, has bought the Monte Carlo.

WHITE PINE COUNTY.

The Rocco-Homestake Co., at Hamilton, is reported to have opened a body of carbonate ore containing values in silver and lead.

NEW MEXICO.

LUNA COUNTY.

The pneumatic concentrator erected at Cooks is to be doubled in capacity.—The contractors who have been trying to

drill an oil well at Deming for the El Paso-Deming Oil Co., are reported to have quit.

OREGON.

BAKER COUNTY.

Superintendent L. C. Beckwith at the Orleans mine, near Sumpter, says the two crosscuts driving on that property have reached the north and south veins. The north vein has 2 feet of ore and the south vein 10 feet. The last 20 feet in the tunnel opened up a shoot.

The Ross Gulch mine is reported sold to Spokane men for \$65,000. The shaft is down 165 feet, with short drifts on the Ross Gulch claim. The sale also includes the Richmond 10-stamp mill and a hoist with a capacity of 1200 feet depth. There is a smaller hoist on the Ross gulch, which has a capacity of 300 feet.

J. H. Robbins, C. C. Robbins and O. C. Wright have incorporated the Baltimore M. Co. to operate the Baltimore group of five claims on Buffalo mountain, on Granite creek.

E. G. Stevenson, H. Holcomb and T. McEwen have incorporated the Blue Mountain G. M. Co. to develop five claims adjoining the Phoenix, Don Juan and Virginia mines near Greenhorn city.

Five shifts of miners are at work on the Dixie Meadows mine, three shifts in the lower tunnel and two in the second level. The lower tunnel is a crosscut, driven to tap main ledge at 500 feet depth.

A two-drill compressor is being put in at the Chloride mine on the Rock Creek slope, near Sumpter. A tunnel is being driven.

Two ore stringers have been cut in the St. Patrick mine, near Sumpter. One is 1 foot in width with talc walls. The main lead is near the face of the crosscut.

C. W. Keizur, M. L. Keizur and Estella Keizur have sold to the Cardwell G. M. Co. six claims in Stice Gulch district, between Sumpter and Baker City.—C. H. Barnard has sold to the Cracker Eagle M. Co. the Pearl placer claim in the Cahle Cove district.—W. Cooper has sold his interest in the Monarch and Oreole property of the Quartzburg district to N. C. Haskell of Baker City.

The tunnel being driven on the Tammany property, near Sumpter, owned by the Northwestern C. I. & L. Co., is in 135 feet, says Manager Butze. The tunnel is in a milling ore, 12 feet wide, that assays \$1 to \$7. The main vein is 30 feet wide. The four claims owned by the company join the North Pole ground. Manager Butze says machinery will be installed.

Fifteen stamps are dropping in the Goldconda mill, near Sumpter, and the other five will be added as soon as the hoist is ready to raise ore from the lower levels. Some ore is being shipped.

The Nine Strike, Nos. 2, 3 and 4, on the Nine Strike vein of the mother lode section, near Sumpter, have been sold to Eastern men for \$15,000. W. T. Young is manager.

The Sanger G. M. Co. has been incorporated to operate the Sanger mine in Eagle Creek district. F. W. Paine, J. E. Bingham, J. K. Romig, F. A. Moore, P. Basche, L. A. Lewis, C. P. Berkey, W. A. Lindsay, W. M. Pierce, J. K. Romig is superintendent.

JOSEPHINE COUNTY.

A 25-foot vein of coal is reported on Dutcher creek, 12 miles from Grants Pass.

The Granite Hill mines of Louise creek district, 8 miles north of Grants Pass, have been bought by the American Gold Fields Co. of Chicago. The deal comprises 800 acres of mineral land, both quartz and placer, together with a 5-stamp mill, concentrator and other equipment. The placer mines are equipped with hydraulic plant, with 7 miles of ditches and flumes, hundreds of feet of pipe and two giants. There are over 600 acres of placer ground in the Granite Hill diggings. W. J. Morphy is manager of the company. The Granite Hill mines have been worked for two years past by C. L. Mangum. The new owners, under the direction of their consulting engineer, W. Devarila, will develop the Granite Hill mines and expend \$75,000 in opening and equipping them.

MALHEUR COUNTY.

Oil is said to have been struck 8 miles from Vale in two wells. Five holes were drilled, and on claims of the Union Co. and of the Zenith Oil Co. oil was found. The oil was struck on the Union Co.'s ground at 100 feet and the Zenith Co. at 150 feet.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The Oro Hondo M. Co., at Lead, whose property joins the Homestake on the south, have the three-compartment shaft down 200 feet. The hoist in operation is designed for a depth of 2000 feet.

A 20% payment has been made by the

Lucky Strike M. Co. on the 210 acres of mineral land bought near Custer peak, 7 miles south of Lead. The property is 1½ mile from the Uncle Sam mine of the Clover Leaf G. M. Co.

According to the report of State Mine Inspector T. Gregory, the total number of miners and mill men employed in the Black Hills for ten months of 1902 averaged 3207, two-thirds of whom were employed by two companies, the Homestake and Golden Reward. It took 1700 men to produce the output of the Homestake, 1,218,089 tons. Total number of tons produced in the Hills in ten months were 1,621,601, valued at \$7,342,227, averaging \$4.60. The average production per man a month for the ten months on the Homestake was seventy-two tons; on Golden Reward, forty tons; all others, same time, twenty-two tons.

A bar of gold bullion valued at \$16,000 was deposited in the United States assay office at Deadwood by the Spearfish G. M. & R. Co. January 2, the result of fourteen days' run at the cyanide plant in Johnson gulch.

The Potsdam G. M. Co., adjoining the Spearfish and Deadwood-Standard properties in the Ragged Top region, is reported to have opened up an 11-foot body of ore.

The Deadwood-Standard G. M. & M. Co., which owns 225 acres of patented ground in Ragged Top mining district, adjoining the Spearfish Co.'s territory, has decided to double the capacity of its mill. The mill at present has a capacity of from 100 to 125 tons of ore daily.

TEXAS.

JEFFERSON COUNTY.

The oil production of the Beaumont field for 1902 was as follows:

	Barrels.
January.....	546,881
February.....	687,961
March.....	813,794
April.....	851,178
May.....	932,411
June.....	1,421,268
July.....	1,036,915
August.....	1,217,779
September.....	828,815
October.....	1,114,065
November.....	937,791
December.....	1,117,624

Total.....11,506,482

The Gulf Refining Co. of Pittsburg, Pa., is erecting at Port Arthur an oil refinery to cost \$1,500,000, and it is expected to be in operation within three months. The Port Arthur refinery will have fifty-eight stills of 1000 barrels capacity each. Twenty-five of these are in use. The plant will have sixteen tubular boilers, fired with oil, and ten agitators to finish the reduction of the product. The entire plant is fed and relieved from 100 tanks, of capacity ranging from 500 barrels to 55,000 barrels each.

HARDIN COUNTY.

A. Merchant has sold 225 acres in the Sour Lake oil field to F. D. Coe of Dawson City for \$50,000. T. Mendelssohn is building a derrick on lot 6 in the Parsons tract. The Guffey Co. has completed the pipe line to Spindle Top, and as soon as pumps are placed will begin to deliver oil to their refinery at Port Arthur.

UTAH.

BEAVER COUNTY.

Superintendent Farish, of the Old Hickory mine of the Majestic Co., reports having cut the ore body at 200 feet in the tunnel. A streak of smelting ore running 40% copper appears in the vein. The tunnel will be continued until it comes in under the shaft. Superintendent Tarbet, at the Estella, states that a body of gold-bearing carbonate of iron has been broken into on the 200 level. According to Tarbet, the whole face of the drift is in ore.

F. H. Lathrop of Salt Lake has an option on the Margaret Williams group, near Milford, for \$45,000. The group adjoins the Old Hickory on the southwest and consists of eight claims. It is Lathrop's intention to sink the 30-foot shaft to 100 feet.

Last week the shaft being sunk on the Erie, near Beaver, cut the vein at 130 feet. At 150 feet a drift will be driven. The ore is iron-copper sulphide.

GRAND COUNTY.

The Toledo G. M. Co. has incorporated. T. R. Black, F. G. Carthey, J. A. Largent, I. Clive, F. Beck, M. I. Fowler and G. L. Nye, to develop mines in the Miner's Basin district.

JUAB COUNTY.

Manager O'Donnell, of the Utonian of West Tintic, says the upraise run to connect the second and third levels is through. This work was necessary to improve air in the lower workings.

Drifting on the vein is resumed on the third level.

During 1902 there were 47 cars of concentrates and 40 cars of bullion shipped from the Mammoth mill and 400 cars of ore from the mine. The Grand Central marketed 463 cars. The largest tonnage was shipped from the Dragon Iron mine, which sent 472 cars. Other Mammoth and Silver properties shipped as follows: Carissa, 268 cars; Lower Mammoth, 153; South Swansea, 122; Swansea, 107; Tesora, mine and mill, 93; Ajax, 61; Victor, 51; Star Con., 46; Mordue Iron, 14; Alaska, 12; Sioux-Utah, 8; Laclede, 5; Martha Washington, 3; Showers, 3; Rabbit's Foot, 2; Undine, 2; and one each for the Boss Tweed, Boston & Tintic and Utah.

S. E. Ware, superintendent of the Swansea mine at Tintic, has a lease on the Sunbeam.

It is reported that D. A. Depue has a lease on the entire Carissa mine, near Eureka. Heretofore the ground has been distributed among eighteen leasers.

Manager Joseph says he expects to be sending Carissa ores out through the Sioux-Ajax tunnel, Tintic district, next week.

In the properties of the Snowflake M. Co., Tintic district, a body of quartz carrying manganese has been cut in the ledge, running northwest and southeast. Manager Hatfield says he is northwest on the ledge, connection with it having been made on the 700-foot level.

The Joe Bowers mine of Diamond, Tintic district, has been leased to G. Paxton. The shaft is down 400 feet. At the west the ledge was cut 50 feet from the shaft but it only showed a mineralization. On the east connection with the ledge was made at 300 feet from the shaft.

From the Centennial Eureka, Tintic, 225 tons daily are being taken out and shipped to the smelters. Manager Allen says 170 men are on the payroll.

PIUTE COUNTY.

There were twenty-three notices of location filed with the District Recorder at Kimberly January 1st.

A company of Chicago men have bought the Copper Queen and Gold Diamond groups of ten claims on Deer creek, near Kimberly. The former owners run two tunnels on the property, to cut three ledges which appear on the surface. One of the tunnels has cut two veins and the other in 150 feet is expected to cut the largest of the three ledges at 200 feet. The new company will begin developments next week.

SALT LAKE COUNTY.

A strike of ore is reported in the Mountain Lake mine, above Brighton, and shipments will begin. From the breast of an old tunnel which was in 700 feet, a crosscut was run to the northwest, and at 100 feet the ledge was found.

The Ben Butler Co. has bought the Pride of America and Bullock Fraction lodes, adjoining the Ben Butler group on the east, near Bingham. Assays made on the ore recently found in the Mystic Shrine lower crosscut and upraise show \$6 in gold, 25 7 ounces silver, 7% lead and 2 2% copper per ton. On account of bad ground, but 29 feet were made in the lower tunnel in December.

The Dewey mill at Bingham is shut down and Manager Beemus says the greater portion of the mill would be remodeled before resuming. While no new machinery will be added, changes will be made to lessen the labor and admit the easier handling of the ore.

The holdings of the Gypsy Blair M. Co. at Alta are sold to the Kennebec. With this addition the Kennebec controls about 340 acres. The upper workings are to be abandoned and the Gypsy Blair ledge tapped through the Read & Benson tunnel, which will cut it at 1000 feet below the surface. The Kennebec Co. has bought the water right at "Mill D," and at that point will install the power plant for its entire system.

It is reported from Pine the lower tunnel of the Copper Boy last week cut a vein of cyaniding ore, carrying \$6 in gold, nine ounces silver, 2% lead.

SUMMIT COUNTY.

Manager A. H. Mayne of the Minola M. Co. at Park City says the shaft below the tunnel level, which is down 200 feet, has cut a body of sulphide ores. The point at which the change occurred is at a vertical depth of 350 feet from the surface.

The zinc reduction plant at Park City has resumed. The plant begins on eighty tons of ore daily; to be increased to 100 tons.

The shaft to the 2000 at the Ontario, at Park City, has been retimbered and men are cutting the station and sinking a sump, after which drifting will begin.—At the Nalldriver Superintendent H. Campbell has the hoist completed and is

putting the engine and compressor in place.

The strike in the Quincy of the Daly-West Co., at Park City, reported by Manager Kirby, is in the crosscut through the porphyry dike on the 400-foot level, and assays show 250 ounces in silver, 30% lead, 6% copper and \$3 in gold. Kirby considers this ore a continuation of the shoot on the 200 level.

TOOELE COUNTY.

At the Grand Cross mine at Stookton ore has been opened up in a 60-foot upraise from the tunnel at 700 feet from the tunnel opening. Manager Reuhousen says the ore carries silver and lead, and that the strike was made in a cross fissure, which intersects the main fissure which the tunnel is to cut.

WASHINGTON.

CHELAN COUNTY.

Manager R. D. Johnson, the Chelan Transportation & Smelting Co., which has a bond on the Holden mine, in the Chelan district, says the company will build a smelter at the Holden to cost \$100,000. Forty men are employed on development work.

FERRY COUNTY.

W. F. Newton, superintendent the Mineral Hill Co., has eleven men working on two shifts on the company's group of twenty-four claims on the east side of the Kettle river, 1 mile south of Danville, near the Canadian boundary. He is operating in two places for the development of the Copper Bullion. The principal work is a shaft 108 feet deep, from the bottom of which a drift has been driven on the vein 300 feet. A crosscut from the bottom of the shaft has intersected the vein 6 feet wide. A stope is started from the shaft and ore is being taken out on three floors. A tunnel is being run to tap the vein 100 feet below the bottom of the shaft. At 75 feet it cut the Minnehaha vein, which is the north extension of the Lucile Dreyfus. The main tunnel on the Lucile Dreyfus is in 300 feet. The winze is down 75 feet on the hanging wall.

The Pioneer-Miner says thirteen men are employed at the Lone Pine-Surprise, near Republic. In the upper workings the stopes have been raised one floor, with the roof 14 feet above the track on the main level. The southwest face samples assayed \$13.60 in gold and 86 cents in silver, and the northeast face assayed \$12 in gold \$3.80 in silver.

P. Clark, president of the Republic Con. M. Co., says their mines near Republic have resumed.

OKANOGAN COUNTY.

Superintendent W. Lewis has the tunnel on the Mammoth mine, on Whisky hill, near Loomis, in 700 feet.

WYOMING.

There are 7148 men employed in the coal mines of Wyoming.

CARBON COUNTY.

The North American Copper Co. has bought the coal mines 9 miles from Rudefeha. The coal will be used at the Ferris-Haggerty mine and will also supply the various plants of the company, being delivered over the tramway.

The average cost per foot in running the tunnel of the North American Copper Co. to unwater the Rudefeha mine, near Dillon, has been \$23, and the total cost \$35,420, not counting lumber, tools, tracks and cars, says Manager W. Bunce. The total length of the tunnel is 1540 feet. It took fifty-seven hours for the mine to drain.

The Octavia tunnel, near Dillon, is in 825 feet and four men are at work. This tunnel is being run to cut the vein that shows on the Syndicate property.

J. Malody and C. Schoonover are working on a 100-foot contract on the Hidden Treasure, near Battle. S. Edgar and R. Ledbetter have filed on eleven claims on Cow creek and begun development.

CROOK COUNTY.

Superintendent W. D. Bartlett of the Monumental Oil Co., operating in the Moorcroft field, says he has one well down 1500 feet.

FREMONT COUNTY.

The Wyoming G. M. Co. of Salt Lake City, Utah, has incorporated; T. P. Steffey, T. A. Helm, W. H. Clark, G. L. Nye and J. A. Largent; to operate the Bullion, Bullion Fraction, Good Luck, George McKay and Venus claims in the Overland mining district.

FOREIGN.

AUSTRALIA.

The prospecting of the Lake View Consols at a depth on lines recommended by the present management is said to have

resulted in an improvement in the mine and an increase in the tonnage of payable ore reserves. In April, 1902, Hoover, Feldtmann & Pritchard estimated that ore in sight in this mine was sufficient to maintain a monthly output of 6000 ounces for twelve months. Since then about 45,000 tons of one-ounce ore have been treated and at present nearly double that tonnage of payable ore is available. The main shaft of this property is down to 1300 feet and will be sunk to 1500 feet.

NEW SOUTH WALES.

Two dredgers in the Inverell district are yielding large quantities of tin. The Cope's Creek Co.'s dredger has cleaned up after a six week's run twenty-five tons of tin and the Wilberforce dredger is yielding three tons of tin per week. Both dredgers are working ground which has been worked and reworked by miners for twenty-five years. As the dredgers are only furnished with rifles for concentrating the tin, only a small proportion of the tin raised is saved.

A new company has been formed in Sydney to buy the Wonga Wonga gold mine, at Wangat. The mine was discovered thirty years ago and successfully worked for years. Owing to the ore carrying a large amount of pyrites at depth, battery treatment did not yield a profit. The ore is low grade, but the lodes are large and regular and yield large bodies of ore.

BRITISH COLUMBIA.

(Special Correspondence). — Rossland Mining Division: John H. MacKenzie's successor as general manager of the Le Roi mine and Newport smelter will probably be appointed at the meeting of Le Roi directors in London, his resignation having been in the hands of the company for some weeks.

Slocan Mining Division: New York men have bonded the Hungry Man property on Rover creek, near Slocan Junction. The group produces pyritic ore, carrying an average value in gold and copper of \$20. Six thousand dollars has been expended in development. The Republic has recently opened 4 feet of rich ore. It is close to the old shaft. After stopping out a carload of ore at the shaft another opening was made 70 feet to the west following down two streaks. These have been stripped for 30 feet and have been found to unite, forming a 4-foot pay streak. It is shipping ore and carries native silver, argentite and gold-bearing iron pyrites. It assays 200 ounces silver and \$7 gold. The first car of ore shipped from the Republic by the new owners, amounting to twenty-two tons, was sent to Nelson. The ore will average 160 ounces silver and \$8 in gold.

Lardeau Mining Division: The Copper Dollar and the Marten fraction, two gold claims adjoining the Eva on Lexington mountain, have been sold to Elwood. Ind., people, who are operating the Western Star, near Camborne. Manager J. A. Darragh says development on the Copper Dollar and Marten fraction will be on a large scale in the spring. It is reported that a strike has been made in No. 7 tunnel of the Calumet and B. C. gold mines, Limited, at the Eva mine, near Camborne. J. F. Musselman is manager. He states that No. 7 tunnel was started six weeks ago, designed to open an ore shoot on No. 2 vein at a depth of 500 feet. Machinery will be installed as early as possible in the spring.

Nelson, Jan. 6.

The Kootenay mine at Rossland has resumed shipments. During January shipments will be made at the rate of fifteen tons per day. At the mine forty men are at work. Ore is being stoped in the third level, the mine being developed for a vertical depth of 1400 feet, entirely by horizontal workings.

The Sandon Paystreak says the Democrat in Alamo basin has been closed down. There are eleven men working on development at the Idaho. Three men are employed at the Sunset and Trade Dollar. It is rumored that development on the Ruth has open up an ore shoot. The Chance closed down January 1 and will not resume until spring. The Payne has thirty men working on zinc ore. The Slocan Star has thirty men drifting and stoping. No. 5 will be under the Silver-smith workings before the end of the month. Hereafter this mine will be operated on a six-day week, all Sunday work having been stopped.

Last week a 150 H. P. electric hoist was installed at the Snowshoe mine, Phoenix camp, at the main shaft.

The coal mines at Crow's Nest pass, south of Kootenay, though tied up for six weeks by a strike, output for 1902 shows an increase of 16,000 tons over 1901. The total output amounted to 441,000 tons of coal and 112,000 tons of coke. The mines at Michel, Coal creek and Morrissey are producing 2000 tons daily.

The Trail smelter at Grand Forks has bonded the Seattle for \$97,000. Develop-

ment work has begun. According to agreement the company will expend \$1000 per month in development. The Seattle is on the west side of the North Fork a few miles below the Volcanic mine.

J. Thompson et al of Fort Steel has a lease on the upper portion of the Invicta placer on Wild Horse creek, together with the lower ditch which carries 1000 inches of water.

Official statistics of southeast Kootenay for 1902 record as follows:

Mining claims recorded.....	253
Certificates of work.....	453
Certificates of improvements.....	12
Free miner's certificates.....	563
F. M. C. to companies.....	8
F. M. C. special.....	7
Mining leases issued.....	16
Mining leases in force.....	25
Mining leases renewed.....	2
Water grants.....	14
Pre-emptions recorded.....	89

The following are the figures for 1902 of the output of coal from the Vancouver Island collieries and the foreign shipments of the New Vancouver Coal Co:

From the New Vancouver Coal Co.:	
Gross output, tons.....	491,302
Shipments, tons.....	401,139

From the Dunsuir collieries:

Wellington mine, tons.....	400,568
Comox mine, tons.....	393,747

Of the total output of 1,291,617 tons a portion was turned into coke at Comox, producing 15,800 tons of coke. The yield for 1901 was 1,261,774 tons. The coke yield of Comox showed an increase of 402 tons over 1901.

Shipments from Rossland camp for the week ending Jan. 9 were:

Mine.	Tons.
Le Roi.....	3,038
Center Star.....	1,110
War Eagle.....	810
Giant.....	50
Velvet.....	50
Kootenay.....	30
Total.....	5,086

By a vote of 245 to 101 the employees of the Le Roi mine at Rossland have decided to adopt the proposal by the management to cease work on alternate Sundays. The Le Roi mine has decided to increase its monthly tonnage by 4000 to 6000 tons, which will make the monthly output 20,000 tons. The Black Bear stope, the extreme western workings on the south vein, has been opened up. At present 360 men are at work. The mine has 37,000 tons of high grade ores in the smelter yards, and the lower grade will be mixed with this reserve, as the matte turned out at the smelter has been carrying values in excess of the company's contract with its refiners.

Of the big mines in the Rossland camp the Le Roi is the only one that has had a continuous year of activity. The Le Roi No. 2, at Rossland, for the first eleven months of 1902 produced 83,076 ounces of gold, 146,449 ounces of silver and 6,697,022 pounds of copper. The profits announced by the management of the Le Roi mine and smelter for the entire year aggregate \$1,000,000. The mine distributed \$463,150.90 in wages to its Rossland employees and \$396,478.31 to its employees in the smelter at Northport.

R. Allen has taken the contract for rawhiding 500 tons of ore from the Hunter V., near Ymir. He has a team of six horses and expects as soon as the trail is in shape to bring down a ton per horse each trip. The rawhiding trail from the mine down the Hidden creek side of the divide has been abandoned and the ore will be brought down by Porcupine creek. The railroad company intends to put in a switch near the Porcupine bridge.

KLONDIKE.

Pipes have been sunk in the El Dora dog gusher, near Dawson, and the work of filling the shaft is reported under way. Eighteen feet of material have been deposited in the bottom of the shaft around the pipes, which are two hydraulic iron pipes, each 8 inches in diameter. They reach to the bottom of the shaft. On the base of each pipe is a large, cylindrical steel vessel, perforated to admit the full flow of water. The cylindrical base is made of heavy steel to resist the side pressure. At the surface the pipes bend and the diameter of each is reduced to 4 inches. The 4-inch portions are short and in them are fixed gate valves to regulate the flow of water.

C. Cole of London, representing English capital, has installed 15 miles from Dawson the largest hydraulic plant taken to the Klondike. The plant will be placed in operation next summer to sluice a number of Bonanza creek claims.

Gradually companies and large hydraulic plants are supplanting the individual miner in the Klondike. The richest placers have been worked out and according

to Cole it is only by hydraulic means that the remaining ground can be made to pay.

MEXICO.

The report of Consul-General A. D. Barlow says the State of Sonora has American capital invested in mining amounting to \$27,800,000, and Chihuahua comes next with \$21,000,000.

The number of smelters in Mexico is increasing. In addition to the smelters at Aguascalientes, Monterey and San Luis Potosi, new works are being built in Guaymas, Avino, Tepeyanualco, Viesca and Saltillo costing \$200,000 each. Four of the smelters have a daily minimum capacity of 600 tons and up to double that tonnage if the ores are supplied. It is proposed to build smelting works in San Luis Potosi, Matohuala and various points in Jalisco, Chihuahua and Durango. The erection of a large smelter in Monterey in connection with the foundry has commenced and is to cost \$500,000; also a smelter is to be built by the Yaqui S. & R. Co. in the Ures district, Sonora. The equipment for the latter is being shipped from Chicago by the Allis-Chalmers Co.

CHIHUAHUA.

S. Dedrick, superintendent of the Sierra Boluda mine, says ore running .83 ounce gold and 17 ounces silver is being taken out. The development work consists of two shafts and a tunnel. No. 1 shaft is down 130 feet and No. 2 180 feet, and the tunnel is in 25 feet and will run 250 feet to crosscut the vein. This property is bonded to the Camrose Syndicate, Ltd., an English corporation; A. F. Nathan general manager.

The Torreón smelter is to increase its capacity to 1000 tons daily by adding two furnaces of 175 tons capacity.

SONORA.

J. C. Underwood, general manager of the gold mines at Yerkes Camp, in the Altar district, reports the installation of a 20-stamp mill, a 60-ton cyanide plant, a 50 H. P. engine, steam hoists and other machinery.

The Gold Coin P. & D. Co. at San Javier have their 50-ton smelter in operation. For fuel they use the natural coke from La Barranca, 4 miles away, which is delivered at the furnace for \$7.50, Mexican, per ton. Some of the ores require concentrating, and a mill will be put up.

QUEBEC.

The New England Asbestos M. & M. Co. has bought the property of the Canadian Asbestos Co., Ltd., at Black Lake, and that of the Beaver M. Co. at Thetford. Although the Canadian Asbestos Co. has sold its mine at Black Lake, it will continue its present business in Montreal.

GALICIA.

On Jan. 8th, in a fire at the oil wells of Boryslav, twenty-seven springs were affected and twenty houses destroyed. The damage is estimated at \$110,000.

SOUTH AFRICA.

Colonial Secretary Chamberlain and leaders of the mining industry at Johannesburg have arrived at an agreement in the matter of financial settlement, under which the Transvaal war contribution will amount to \$150,000,000, which is to be expended in public work in the Transvaal and Orange River Colony. Regarding the labor question, it is believed the Imperial Government will consent to the importation of Chinese laborers for the mines.

The report of the De Beers Con. Mines, Ltd., of South Africa, for last year, shows gross earnings of \$23,435,970, and net of \$10,813,545. With other income from investment equal to \$601,140, and a previous surplus of \$6,386,705, the total funds available were \$17,801,400, from which were paid life governors' remuneration of \$1,582,970, and dividends and bonuses of \$12,220,000, leaving a surplus of \$3,993,430.

PERSONAL.

W. H. W. HAMILTON has returned to Sumpter, Or., from the East.

D. A. McDONALD leaves Berkeley, Cal., on the 19th for Valdez, Alaska.

W. VINCENT is superintendent of the Hull mine, near Groveland, Cal.

W. D. ARNOLD of Georgetown, Colo., has gone East on mining business.

C. W. HASKELL is manager the Melrose G. M. Co., near Florence, Colo.

F. LUNDSTRUM of San Francisco, Cal., is examining mines in Tonopah, Nev.

W. A. HILDRETH, president of the

Oriole M. Co., is at the mine near Angels, Cal.

F. A. ENOS has resigned as manager the Bellevue mine, near Sonora, Cal.

T. FAIRCHILD is superintendent of the Manhattan mine, near Robinson, Utah.

J. H. MACKENZIE has resigned as manager Le Roi mines, Rossland, B. C.

W. CAMPBELL is superintendent the Owenby Leasing Co., Cripple Creek, Colo.

S. TURNER is superintendent of the Calumet & Bisbee D. Co. mine, near Bisbee, Ariz.

C. F. MASEY, superintendent of the Iron Springs mine at Iron Springs, Idaho, is in the East.

JAS. BARTREM has resigned the superintendency of the Prosperity mine, Prescott, Arizona.

W. E. THORNE, formerly of Georgetown, Cal., leaves Denver, Colo., on the 21st for Alaska.

C. L. LANG of Sonora, Cal., is superintendent Con. North Star-Carlotta group, near Carters, Cal.

I. G. SHEPPARD has returned to San Francisco from examination of mine property at Selma, Cal.

W. Q. BROWN, manager of the Coeur d'Alene M. Co., has returned to Murray, Idaho, from Oregon.

E. P. WHEELER, manager of the Mineral Hill mine, near Concouly, Wash., is at Whitingham, Vermont.

J. O'REGAN, superintendent of the Last Chance mine, near Sandon, B. C., has gone to New Brunswick.

B. BLANCHARD, superintendent of the Iron King, near Val Verde, Ariz., has returned from New York City.

MANAGER M. SIDNEY of the East Argentine M. Co., Georgetown, Colo., has gone East on company business.

F. J. MARTIN, superintendent of the Fortuna mine, near Yuma, Ariz., has returned from San Francisco, Cal.

W. B. DEVEREUX, of Colorado Springs, Colo., consulting engineer Melones M. Co., Melones, Cal., is at the mine.

GEO. W. INGLIS, representing the Stilwell-Bierce & Smith-Vaile Co., Dayton, Ohio, is in San Francisco, Cal.

T. H. OXNAM has gone to London to attend the annual meeting of the Palmarajo and Mexican Gold Fields, Ltd.

W. NEBEKER has returned to Salt Lake City, Utah, from examining mining properties in Mexico and Arizona.

W. F. SNYDER, manager of the Western Exploration Co. Balakala mines, near Keswick, Cal., is in Salt Lake City, Utah.

MANAGER W. BUNCE and Auditor A. E. Loizeau, of the North American Copper Co., Dillon, Wyo., are in Denver, Colo.

W. E. C. EUSTICE, of Boston, president Melones M. Co., Melones, Cal., is in San Francisco, Cal., from a trip to the mines.

G. C. GILL, of Holyoke, Mass., president of the Shannon Copper Co., at Clifton, Ariz., has returned from a visit to the mine.

N. J. SORESENSEN has resigned the management of the Maxwell mine, of the Elkhorn Con. G. M. Co., in Rock Creek district, Or.

F. R. CULBERTSON of San Francisco, Cal., general manager of the Chloride-Bailey mine, near Trinity Center, Cal., is at the mine.

F. D. FRENCH is manager the Owenby Leasing Co., operating the Pharmacist, Acacia and Isabella properties, Cripple Creek, Colo.

MR. CORBOULD has resigned the management of the Hannan's Reward-Mount Charlotte mine, Kalgoorlie, Western Australia.

E. H. BENJAMIN of San Francisco, Cal., is at the Golden Eagle mine at Hayden Hill in Lassen county, Cal., of which he is consulting engineer.

W. M. NESBIT, of Tintic, Utah, has accepted the position of manager the Cortland group of mines in Gold Brick district, Gunnison county, Colo.

S. H. LUCAS, general manager Cuyamaca & Stonewall Ranch M. Co., has gone from Los Angeles to Cuyamaca, Cal., to open up the Stonewall mine.

J. T. MILLIKEN, formerly chemist for the Imperial G. M. Co. at Deadwood, S. D., is mill superintendent for the same company, vice W. B. Milliken, resigned.

K. YAMAGUCHI, Ph. D., representing the Furukawa Central Office of Mines at

Tokio, Japan, is in British Columbia looking into copper smelting methods.

H. HOLMAN is superintendent the Wedekind mine, near Reno, Nev., vice C. L. Crane, resigned. He will also act as superintendent of the Desert King mine.

S. BAMBERGER has resigned the position of president and general manager of the Lower Mammoth mine at Tintic, Utah, to devote more attention to his De Lamar mines in Nevada.

WM. STEPHENS is superintending the construction of a complete hoisting plant for the Joshua Hendy Machine Works, on the property of the Fresno Copper Co., of which H. B. Varcoe is manager, near Clovis, Cal.

S. A. JOSEPHI, manager American Exploitation Co., Denver, Colo., with E. M. Farr, representing Washington, D. C., capital, have returned from Kingman, Ariz., where they had been investigating the Gold Creek M. Co.

Books Received.

"A Treatise on Roads and Pavements" is the latest volume on this important subject. The author, Ira Osborn Baker, C. E., is an authority on this subject, and also on masonry. The book consists of 655 + viii pages, 171 figures and 68 tables. It deals with road economics and road location. The chapter on gravel roads contains the first scientific study of road-building gravels. That portion devoted to broken stone roads is filled with practical minute details not ordinarily found in books. The chapter on asphalt pavements is very complete and contains the first discussion of the causes of failure of asphalt pavements ever published. Wheelmen will be interested in the article on bicycle paths. Price \$5. John Wiley & Sons, New York City.

Commercial Paragraphs.

ECCLIS & SMITH, Fremont street, San Francisco, have this week booked orders for a carload of Braeburn mining drill and tool steel. This firm also handle "Boyer" hammers and "Little Giant" drills.

THE California Hyd. Eng'r Supply Co., San Francisco, Cal., have shipped and are now installing a 10-stamp mill with hydraulic power at the Altadena mine, at Columbia, Cal. They are also installing a gas engine and pump at the Int Jefferson Consolidated at Chinese Camp, Cal.

THE Llewellyn Iron Works of Los Angeles, Cal., have closed contract with Messrs. Thomson & Boyle of the same place for a 100-ton ore reduction plant to go to their mine near Mojave, Cal. The plant contains three sets of their improved rolls, crusher, screens and all auxiliary machinery with complete power plant. They will erect the machinery on foundations and put up the building complete with everything ready to run. The plant is to be completed in ninety days.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CONVEYERS.—No. 717,063. Dec. 30, 1902. C. J. Allen, San Francisco, Cal. The object of this invention is to provide a simple means by which a burden carrier may be taken up at one point, moved to a place of discharge and the carrier returned to the point of beginning by gravity. It consists of a rigid inclined single track, hoisting and fall cables respectively, attached to the higher and lower ends of said track, sheaves supported in line with and at points above the respective ends of the tracks and through which said cables pass, the fall cable adapted to raise or lower in unit on with the hoisting cable, a burden carrier comprising a trolley and bucket, said trolley adapted to be easily engaged with and disengaged from said cables and having anti-frictional guides engaging the sides of the track, said bucket consisting of a hinged tilting scoop, and means for locking the bail and scoop when the latter is to be hoisted.

CONCENTRATORS.—No. 717,805. Jan. 6, 1903. J. S. Brownell, San Francisco, Cal. This invention relates to improvements in apparatus for concentrating and separating valuable heavy material from the lighter waste or gangue as applied to machines in which an endless traveling belt is mounted at an angle and gradually moved up the incline and at the same time given a shaking movement. This class of machines is sometimes called "rammers." The invention consists in certain details by which the driving gear actuating worm can be disconnected to stop the travel of the belt while allowing the shaking movement to proceed, means for mounting the worm-driving shaft, and for shifting the driving belt upon the cone pulleys to vary the speed of travel. It also comprises improvements in the spring supports

upon which the frame is mounted and the manner of adjusting the pulleys over which the pulley-carrying belt passes.

RAILWAY RAIL AND THE DISTRIBUTOR.—No. 717,830. Jan. 6, 1903. W. P. Cunningham, Coulee City, Wash. This invention relates particularly to means for distributing ties and rails along the graded roadbed. It consists of tie and rail conveyors supported at either side of the construction cars, means for driving the conveyors to send the ties and rails forward, a turntable supported above the ground, upon which the ties are delivered from the conveyor, and a wagon having a horizontal endless carrier with speeling fingers thereon, said carrier adapted to be operated in either direction, first to be loaded from the turntable and then to discharge its load at proper intervals.

MINING PUMP.—No. 717,852. Jan. 6, 1903. J. K. Hogan, Placerville, Cal. The object of this invention is to construct the pump as to avoid the use of all leather valves in the plungers, and generally such parts as are liable to wear and deterioration by the constant action and lifting of a heavy column of water, a means for connecting a series of pumps with pump rods or pitmen common to all of the series, and in so arranging the alternate movements of the pair of pump rods through which motion is communicated that the weight of each descending rod is transferred to assist in operating the ascending rod and plungers actuated thereby. This invention is especially designed for use in mines or wherever water is to be raised to a considerable elevation.

PHOTOGRAPHIC PRINTING FRAMES.—No. 717,853. Jan. 6, 1903. A. Holmes, Sacramento, Cal., one-half assigned to F. Werner of Sutter Creek, Cal. The object of this invention is to provide a frame adapted for use with films as distinguished from the glass plates used in photographic apparatus; and it is a frame of the kind designed and adapted for use with films smooth and flat in the frame while placing the sensitized paper end pre-exposed in place. The invention consists of a rectangular frame, a ledge on the inner wall of the frame opening, a pressure board adapted to rest on said ledge and having a panel portion project into the space enclosed by said ledge. There are grooves formed in the ledge, and a slot in one end of the frame coincident with said grooves, end through which a negative may be introduced into the frame.

MECHANICAL MOVEMENTS.—No. 717,901. Jan. 6, 1903. J. D. McFarland Jr., Fruitvale, Cal., one-half assigned to J. Bruckman of San Francisco, Cal. This invention consists essentially of three tracks or guides lying in the same general plane and extending in the same general direction. A switch arm is pivoted to swing from side to side against one or the other of the outer tracks. Arms are pivoted on the outer tracks and each arm is connected with the switch on the opposite side thereof, whereby the oscillation of the arm in one direction acts positively to cause the switch to oscillate in the same direction; and there is a carriage reciprocable between the ledge, and adapted to engage the switch and cause the carriage on its return movement to travel upon another track. This invention is designed particularly for an engine of the four-cycle oscillating explosive type.

EXCAVATORS.—No. 717,835. Jan. 6, 1903. W. H. Fulcher, Oakland, Cal., one-half assigned to H. Murphy of San Francisco, Cal. This invention is especially designed for excavating earth so as to form canals or ditches, and to transfer said earth from the channel and deposit it upon either side thereof. It consists of an apparatus so mounted that the bearing portion may travel upon the surface adjacent to the excavation to be made, while the excavating mechanism is adjustably supported so that it may be lowered and set to any desired depth, said mechanism being so constructed as to be consecutively loosen and take up the earth and then upon such an angle of inclination as will produce the proper slope in the sides of the channel. There are also means for opening the hockets when they reach the point of discharge, and means for insuring the discharge of the material from the buckets.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR THE WEEK ENDING JANUARY 6, 1903.

717,547.—AIR PUMP OILER.—W. Cooper, Seattle, Wash.
717,805.—CONCENTRATOR.—J. S. Brownell, S. F.
717,807.—FLOATING FISH TRAP.—A. C. Burdick, Seattle, Wash.
717,830.—RAIL DISTRIBUTOR.—W. P. Cunningham, Coulee City, Wash.
717,740.—CAR COUPLING.—C. S. Enright, Tacoma, Wash.
717,835.—EXCAVATOR.—W. H. Fulcher, Oakland, Cal.
717,849.—WASHING MACHINE.—S. Hayes, Ellensburg, Wash.
717,852.—MINING PUMP.—J. K. Hogan, Placerville, Cal.
717,853.—PHOTO PRINTING FRAME.—A. Holmes, Sacramento, Cal.
717,955.—BOTTLE HOLDER.—W. T. Holton, River-side, Cal.
717,682.—LOADING DEVICE.—Honeck & Hopkins, Seattle, Wash.
717,683.—BUOYANT SAFE.—Honeck & Hopkins, Seattle, Wash.
717,855.—LOCK.—S. C. Houghton, S. F.
717,579.—PIPE WRENCH.—L. W. Johnson, Jerome, Arizona.
718,008.—AIR HEATER.—T. S. Lowe, Los Angeles, Cal.
717,882.—BALL AND SOCKET JOINT.—J. C. Martin, Jr., S. F.
717,901.—MECHANICAL MOVEMENT.—J. D. McFarland, Jr., S. F.
717,701.—WAGON LOADER.—J. Murphy, S. F.
718,058.—PAPER HOLDER.—A. E. Sexton, Los Angeles, Cal.
717,937.—OIL BURNER.—G. W. Smith, San Jose, Cal.
717,639.—DUST PAN.—G. C. Tichenor, Los Angeles, Cal.
717,738.—RAILWAY CURVE.—A. C. Wells, Whittier, Cal.

Latest Market Reports.

SAN FRANCISCO, Jan. 16, 1903.

METALS.

SILVER.—Per oz., Troy: London, 22d (standard ounce, 925 fine); New York, bar silver, 47½c, refined (1000 fine); San Francisco, 47½c; Mexican dollars, 38 @ 39c San Francisco, 38½c New York.

Silver again shows a slight decline from last week's quotations.

COPPER.—New York: Standard, \$11.50; Lake, 1 to 3 casks, \$12.25; carload lots, \$11.30; Electrolytic, 1 to 3 casks, \$12.12; carload lots, \$12.00; Casting, 1 to 3 casks, \$12.00; carload lots, \$11.10. San Francisco: \$14.00. Mill copper plates, \$17.00; bars, 18@24c. London: £52 18s 9d spot per ton.

This week's prices show another small advance in prices of all grades except electrolytic.

LEAD.—New York, \$4.12½; Salt Lake City, \$3.50; St. Louis, \$4.00; San Francisco, \$4.50, carload lots; 4½c 1000 to 4000 lbs.; pipe 5½, sheet 6, bar 6½c; pig, \$4.75. London: £11 5s per ton.

SPELTER.—New York, \$4.90; St. Louis, \$4.50; London, £20 per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9½c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 10c; 300 to 500 lbs., 11c; 100-lb. lots, 13@15c.

TIN.—New York, pig, \$28.00@28.90; San Francisco, ton lots, 29c; 500 lbs., 29c; 200 lbs., 29½c; less 30c; bar tin, 35c. London, £125 7s 6d spot.

PLATINUM.—San Francisco, crude, \$18.00 per oz.; New York, ingot, \$19.00 per Troy oz. Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, \$45.50@46.50; large lots: London, £8 15s; San Francisco, local, \$45.50 per flask of 7½ lbs.; Denver, \$49.50. Export, \$43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 35c; Eclipse, 37½c.

ALUMINUM.—New York, No. 1, 99½c pure ingots, 35c; No. 2, 90½c, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 19c; San Francisco, Plumbers', 100-lb. lots, 16.10c.

NICKEL.—New York, 50@60c per lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$22.00; gray forge, \$20.15; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$28.00@30.00; open hearth billets, \$30.50@34.00; San Francisco, bar, 7c to 12c per lb.

GENERAL SUPPLIES.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload

lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kgds, \$1.50 per keg; less car lots, \$2 per keg.

CAPS.—3x, \$5.50 per 1000; 4x, \$6.50; 5x, \$8; 10x, in lots not less than 1000.

FUSE.—Triple tape, \$3.60 per 1000 feet; double tape, \$3.00; single tape, \$2.65; Hemp, \$2.10; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10½c per set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98½-99%, jobbing, 25@26c per lb.; carloads, 24@24½c; in 10-lb. tins, 35c; sulphuric acid, in carboys, 66½ B, 2c per lb.; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 2½@3c per lb.; blue vitriol, 5½@6½c per lb.; borax, concentrated, 7@8c per lb.; chlorate of potash, 12@13c; roll sulphur, 4@6c; ground sulphur, 4@6c; flour sulphur, French, 2@3c; alum, \$2.00@2.25; California refined, 2 @ 2½c; nitric acid, in carboys, 8c per lb.; caustic soda, in drums, 3@4c per lb.; Cal. s. soda, bbls., \$1.25 @1.50 per 100 lbs.; sks., \$1.05; chloride of lime, spot, \$3.00@4.00; nitrate of potash, in bbls., 8c; caustic potash, 10c in 40-lb. tins; sulphide of iron, 9c per lb.; copper sulphate, 5@7c.

CEMENT.—Germania, \$2.50@2.75; K. & B. S., \$3.00; Hewnmoor, \$2.90; Trowell, \$2.90; Portland, \$2.50@2.75 per bbl.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.50; Seattle, \$8.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lots, Eastern and foreign: Wallsend, \$6.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8; Cumberland, \$12; Cannel, \$9.00; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13 in sacks; Sunnyside, \$8.50, long ton.

OILS.—Linseed, boiled, bbl., 56c; cs., 61c; raw, bbl., 54c; cs., 59c; lots of 5 bbls., 1c less; Lucol oil, boiled, bbl., 50c; cs., 55c; raw, bbl., 48c; cs., 53c. Kerosene—Pearl, per gal., 22½c; Astral, 22½c; Star, 22½c; Extra Star, 25½c; Eocene, 24½c; Elaine, 27½c; Water White, in bulk, 16c; Mineral Seal, iron bbls., 18½c; wooden bbls., 21c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 21c; do., cs., 27½c; 63° Naphtha or Benzine, deodorized, in bulk, per gal., 16c; do., in cs., 22½c; Lard Oil, No. 1 bbl., 95c; cs., \$1.00; Neatsfoot Oil, bbl., 70c; cs., 75c; No. 1 bbl., 55@57½c; cs., 57½@60c; Sperm, crude, 50@60c; Natural White, 65c; Bleached do, 70c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: Five tons and over at one purchase, per lb., 6c; 1 ton and less than 5 tons, per lb., 6½c; 500 lbs. and less than 1 ton, per lb., 7c; less than 500 lbs., per lb., 7½c; in 25-lb. tin oals, 1c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs per case, 2½c per lb. above keg price. Dry Lead—in bbls., 1 ton and over, 6c; do. in kegs, 6½c.

RED LEAD.—One ton and over at one purchase, per lb., 6c; 500 lbs and less than 1 ton, per lb., 6½c; less than 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8 @9c per lb.

BONE ASH.—Extra No. 1, 5@6c per lb. No. 1, 4@5c.

BORAX.—Concentrated, 7@9c per lb.; powdered, 9@12c; fused, 25@30c.

BISMUTH.—Subnitrate, per lb., \$1.60.

BONE ASH.—4c per lb.

BORAX.—Crystal, 7c; calcined, 25c.

CHROMIUM.—(90% and over) per lb., \$1.25.

COPPER.—Sulphate, 5@7c.

MANGANESE.—(90% and over) per lb., \$1.25.

MERCURY.—Bichloride, per lb., 90c.

MOLYBDENUM.—25c per gramme; 1000 grammes=2½ lbs.

PHOSPHORUS.—(American) per lb., \$1.00.

SILVER.—Chloride, per oz., 75c; nitrate, 55c.

SODIUM.—Metal, per lb., \$1.25.

URANIUM.—Oxide, per lb., \$3.50.

ZINC.—Metallic, chemically pure, per lb., 50c; dust, per lb., 10c; sulphate, per lb., 04c.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

THE CALIFORNIA DEBRIS COMMISSION having received applications to mine by hydraulic process from C. J. Graham in Selby Hill Gravel Mine, near Nevada City, Nevada County, Cal., draining into Brush Creek which reaches South Fork of Yuba River from Princess Hydraulic Mining Co., in Princess Hydraulic Mine, near Redding, Shasta County, Cal., draining into Clear Creek which reaches Sacramento River; and from Henry Gutenberg in Gutenberg Gravel Mine, near Marysville, Colusa County, Cal., draining into Willow Creek which reaches Consumes River, gives notice that a meeting will be held at Room 96, Flood Building, San Francisco, Cal., Feb. 2, 1903, at 1:30 p. m.

Abating the Smoke Nuisance.

All great reduction works, where sulphide ores are roasted and smelted, produce great volumes of smoke and sulphurous fumes, which destroy all vegetation in their vicinity, and, if not detrimental to health, are at least obnoxious to those who have to live in the smoke and sulphur-laden atmosphere. Butte and Anaconda, Mont., are no exception to the rule, and the "smoke nuisance" has been a cause for much discussion and unfavorable comment in that section. The Anaconda Company has undertaken the difficult task of abating the nuisance, and has been making a series of experiments in that direction, it is now announced, with a probability of success. The experimenters have approached the proposition from several directions, and say they are in a fair way to lessen, if not wholly abate, the smoke nuisance. The most rational method of dealing with the proposition—that of passing the gases through a constantly falling spray of water—they declare to be inexpedient, owing to the large volume of water required, and the inability to recover the substances taken up by the water, which pollute the streams of the region—a greater evil and more widespread than that caused by the smoke. The Anaconda smelters treat about 5000 tons of ore daily and the quantity of dust and gases resulting from the various metallurgical processes is very great, but it is thought that a solution of the problem will be found in the construction of additional dust chambers.

One feature of the proposition is that prior to the erection of the reduction works at Anaconda there was practically nothing of great value there, the subsequent growth of the town and consequent value of real property being created by the metallurgical industry in operation there. Wherever smelters are in blast there is always more or less smoke, and this fact is known to all, and it would seem that as the prosperity of the country depends upon the successful and continuous operation of the reduction works that the smoke nuisance is a matter of secondary consideration, being necessarily incidental to the continuance of the industry.

An Obnoxious Bill Killed.

The passage of a joint resolution by the California legislature, protesting against what is known as the "Dick scripper bill" by Congress, is legislation that will be appreciated by miners everywhere. The Dick bill provided that the Court of Appeals of the District of Columbia should have jurisdiction over the decisions of the Department of the Interior affecting the taking up of lands on the public domain. The evident purpose of the bill was to reopen the oil land cases in Kern county, Cal., which have been decided adversely to the scrip locators since January 1, 1902, for the bill contained a provision which permitted appeals to be taken in any cases decided subsequent to that date. As the law exists, the decisions of the Department of the Interior are final in all matters affecting the location of lands on the public domain, and in all cases coming before the courts they simply affirm or follow the principles established by the Interior Department in its rulings.

Immediately after the passage of the joint resolution by the California legislature, the text of it was sent to Washington, where it was introduced into the Senate by Senator Perkins, of California, and it is understood that the Dick bill will not be reported by the Senate judiciary committee. Had this bill become a law, it would have resulted in almost interminable and expensive litigation in the Kern county oil field.

Early in 1901, Commissioner Hermann decided in the cases of the Kern Oil Co. vs. Clarke, and Gray Eagle Oil Co. vs. Clark, in favor of plaintiff. Both cases involved title to valuable lands in the Kern oil field, and the decision was affirmed by the Secretary of the Interior in April, 1902. In these decisions the Secretary of the Interior made the policy of the Interior Department in relation to lands of this character positive. The opinion of the Secretary was that the provision that forest reserve scrip selections could only be made on vacant land has reference to the physical condition of the land, and does not permit of the selection of land occupied for mining or other purposes, even though such land has not been entered at the local land office.

Many rulings had previously been made which did not look upon the occupancy of land for the alleged purpose of mining as any evidence of its real character, or proper classification as mineral land.

Much land located as mineral (oil lands, placers and veins), if not valuable for the mineral they actually or probably contain, are of little value for any other purpose, and miners do not usually locate land under the mining law without reasonable evidence, physical or otherwise, that it is more valuable for mineral than for any other purpose. The now valuable lands in the Kern river oil section laid for many years unoccupied, untitled and unvalued, and those holding forest reserve scrip would make no haste to locate such lands for agricultural purposes, or for any other purpose than to be benefited by their probable value as mineral land.

It is rarely that the absolute or even the approximate value of undeveloped mineral land can be determined, and lands in the vicinity of known mineral lands, when occupied for the purpose of mining, which means primarily the purpose of proving their value, should be recognized as mineral. This is due to the miner and is only in line with common sense.

In the case of many valuable placer mines, miners of experience decide without hesitation the probability of value underlying the surface and yet the physical aspect of the surface may convey no hint to those unfamiliar with mining of the probable or possible value underlying such surface. The decision of the Interior Department that bona fide occupation of a placer mining location shall be sufficient to vest in the locator an exclusive conditional grant, should extend to oil lands and to all other mineral lands wherein the value must be determined by exploration.

A GREAT manufacturing enterprise is gold mining! There is unlimited raw material with a constant cash demand for modern machinery. The product is wanted by everybody and there are orders ahead for many years' output no matter how great that output may be. The product sells itself. The price is fixed and unvariable—\$20.67 per ounce. Its sale needs no service of agent or intermediary; it

sells itself. Freight on it is reduced to a minimum. Its market is anywhere and everywhere. Times good or bad make no difference, except that when times are dull it sells best. No matter who else engages in the business the demand and the price are unaffected. It is a business in which there is neither competition nor combination. It is an industry that creates and maintains all other trades and interferes with none of them. Its production makes the best of home markets; its manufacture causes the creation of new wealth. It is the developer of communities, the creator of all that goes by the name of progress, development, civilization. In its wake spring up all the arts and sciences which it employs at the highest going wages. It calls to its aid the skilled service of the smartest men and offers reward commensurate with the amount and value of the effort. Better than any other manufacturing industry in the amount, the size and the permanence of its dividends, it is unaffected by trusts and is independent of and immune from the disasters to which other forms of manufacture are liable in the fact, that its product is forever sought in unlimited quantity, for it sets the standard of the world's wealth. The sale of its product is stripped of the expenses that divest other manufactures of their greatest profit, and the product is the quickest got to market of anything that man produces. Such is the business and industry of gold mining. Of what other human industry can so much be truthfully said!

A Labor Famine.

The problem of obtaining a sufficient supply of cheap labor to operate the mines of the Rand in South Africa still remains unsolved. Colonial Secretary Chamberlain the past week received a committee of prominent mine managers and has agreed to throw open Nyassaland and British East Africa for the purpose of recruiting natives, and made a further proposition that the Government import 5000 laborers, on condition that the mines import an equal number, the Government laborers to be employed on public works and in railroad construction. To this the mine operators did not give ready assent, objecting to any control of the Government in the matter. Just how native laborers are to be obtained in those sections of Africa to be thrown open as a possible market has not been determined, though it has been suggested that the natives be impressed for stated terms of comparatively short duration—a species of slavery, in fact, though the laborers so obtained were to be paid as though they served voluntarily.

The labor question has always been a serious one on the Rand, even prior to the war. It was then difficult to secure the services of native laborers who were willing to remain for a length of time which would make it profitable to educate them in mining practice and methods to a point where their services would be of value.

While undoubtedly the vast population of central Africa is able to supply the required number of men and boys, if there are unwilling workers, it would seem that it would be advantageous to employ skilled white miners, whose intelligence and skill would offset their increased pay. The African natives are said to be fairly good workers, but are efficient only in some branches of the work required. In drilling they become experts in putting in "down holes," but can not strike "uppers" to advantage, and for this reason they are largely employed in shaft sinking where it is done by hand. It is stated by those who have given the subject attention that unskilled white labor is not as satisfactory as unskilled black labor, and that the cost of moving material per ton with white labor in shaft sinking is greater than with black labor, and "the only advantage of employing white labor is in the saving of time." This statement appears to be paradoxical, as in view of the large capital invested, the "saving of time" would appear to be a very important factor in economy. The record-breaking shaft sinking in the Woluter shaft, where in November 209 feet were sunk, was all done with skilled white miners aided by unskilled white laborers. Of course, this was accomplished under unusually favorable conditions, such as are rarely found in America. Moreover, these records in shaft sinking on the Rand are made usually, if not always, under the premium system, which operates advantageously wherever tried.

CONCENTRATES.

COMPRESSED AIR installations are used with pressures up to 3000 pounds to the square inch.

A GOOD SOFT CLAY, though wet, will carry from two to three tons per square foot, without excessive settling.

A BELT will only transmit 65% as much power with an arc of contact of 90° as it will when the arc of contact is 180°.

THE Archean is the oldest geological formation recognized. It lies at a lower geological horizon than the Algonkian.

THE Bay Counties Power Co., Cal., is successfully transmitting electrical power, with a pressure of 40,000 volts, 223 miles.

COPPER CARBONATE is of two kinds: Malachite (green carbonate) and azurite (blue carbonate). It is never brown. The brown color is probably due to hydrous iron oxide, though copper may be present.

MILL TAILINGS should contain very low values before they are allowed to run to waste, otherwise a day will probably come when these useless tailings may afford profit. This is a general principle that is being constantly proven.

GREASE OR OIL of any description, whether mineral animal or vegetable, seriously interferes with amalgamation in stamp batteries or pans. It has never been demonstrated that one kind of grease or oil is less objectionable than another.

IN making blue prints a good way is to write that desired in acid-proof ink, then with a ruling pen put a blot of soda over the spot. This whitens the background and turns the ink jet black. The white spot is there to stay and the ink will not fade.

GRAY COPPER ORE (tetrahedrite) is a very complex ore and varies considerably in composition. Its most common constituents are copper, antimony and sulphur; but it also sometimes contains lead, iron, zinc and mercury, as well as gold and silver.

WHEN an engine is carrying its full load the cut-off takes place at one-quarter stroke with a free exhaust; adding three or four pounds back pressure causes the point of cut-off to be lengthened, which means that more steam is taken from the boilers.

IT is bad practice to admit cold water to a heated steam boiler. Some form of water heater should be employed to heat the water before it goes to the boiler. It will save a large percentage of fuel. In a steam plant the exhaust may be profitably employed in heating water.

TO PRODUCE a solution of zinc chloride a chloridizing roasting of the ore is an ancient expedient. And as long ago as 1844, Henderson patented a process wherein after precipitation of the copper by means of metallic iron, to throw down the zinc, together with some of the iron by means of milk of lime.

HYDROGEN DIOXIDE will remove powder stains from the face. First wash the face thoroughly, then keep it covered with pieces of lint saturated with glycerine one part and hydrogen dioxide three parts. In two to three days all the small particles and stains are thus removed, and the black marks healed clean.

A NEW COMBINATION of old elements, in which an old result is got in an easier or cheaper way, is susceptible of protection by a patent. The fact that a patented device or combination has displaced another which had formerly done the same thing or served the same purpose is evidence that it involves invention.

WHERE a vein passes out of the side line of a claim on its strike the extralateral right ceases at the point of such crossing, but the extension of the vein may be secured by a separate location along that portion of the vein passing out of the side line of the prior location, provided the land is not claimed by another.

A COLD CHISEL which repeatedly breaks when chipping hard metal will be found to be much improved if the temper be drawn to a medium straw color, polished, reheated and drawn again to medium straw color—this to be done three times before using. The tool will be found to have the desired hardness and will not break.

CARBON brushes are considered preferable to those made of copper gauze, though a well-designed dynamo or motor will run sparklessly whichever type of brush is used. The chief drawback against their general adoption is their low current-carrying capacity, it being possible to run copper gauze brushes at four times the current density that is advisable with carbon brushes.

NO ALUMINUM alloy containing more zinc than alu-

minum has any particularly valuable mechanical properties. An alloy of two parts aluminum and one part zinc, however, is superior in many respects. It has a tensile strength of about twenty tons per square inch, does not readily oxidize, melts at 425° C. and takes a high finish. It shrinks about 17% when in the process of alloying.

TO "DENOUNCE" a claim in Mexico is similar to "locate" in the United States. In the Mexican mining code "denounce" implies the taking legal possession of a particular portion of any vein, worked or unworked, known or unknown, which a miner chooses for his operations. There is no limit to the number of "denouncements" any person may make, and, as "locating" in the United States, this privilege is abused in Mexico.

THERE is nothing in the Revised Statutes of the United States which prohibits one from making a location of a mining claim by an agent. As the title comes from appropriation made in accordance with the law, it is not necessary that the person in whose name the location is made should be present. A person may locate a claim in the interest of several, and may have the claim recorded in the name of himself and the others not present. When a location is made by one in the name of others, the persons in whose interest the claim is made become vested with the legal title to the claim, and the estate so acquired cannot be divested by making a second location of the same ground, leaving out the names of the original locators, so long as the first location remains valid.

AN engineer should be a good buyer and entirely free from prejudice and open at all times to conviction; he should be ready to improve on his present methods and ought to be in a position to weigh well the two things that make coal, oil and supplies cheap, and of good value. Prices and value have to be considered, and where the two together show a decided improvement upon his present buying he ought not to hesitate in making a change, preference being given to old friends, but only when the market value and quality of goods are the same. Sentiment cannot, from a business point of view and his duty to his employer, be allowed to enter into the calculation of actual value. There is one way in which the engineer in buying supplies can keep up to date and well posted, and that is by reading carefully the announcements of our advertisers.

THE Mexican mining law recognizes two classes of minerals. The first class includes all such mineral substances as may be exploited without obtaining a concession from the Government. The second includes those which may be worked without concession. In the first class are gold, silver, copper, platinum, mercury, lead, tin (excepting placer tin), zinc, antimony, nickel, cobalt, manganese, bismuth, arsenic and iron (except bog ore, alluvial ore and ochres for coloring materials), whether all of these substances are found native or as ores in combination with other minerals. It also includes precious stones, rock salt and sulphur. Those minerals which may be mined without concession are mineral oils and mineral waters; country rock, as granite, marble, sandstone, etc., which is to be used either for itself or as raw material for ornamentation or construction; all soils, as clay, sand, etc.

GRANITE is often referred to as a primitive rock, when in fact most granites are intrusive and of relatively recent age. The granodiorites of California were evidently intruded later than the Jurassic, if the contact phenomena observable at many places can be considered a reliable index of geological age. The primitive rock is difficult to find, as the oldest rocks—the Archean—are largely fragmental, representing the accumulation of debris from the degradation of a still older terrane. The Archean formations are determined on lithological grounds, as they contain no fossils. Typical exposures are found in Canada. They are divided into two series, Laurentian, the older, and Huronian, the younger series. The distinction between Algonkian and Archean rocks is not clearly defined, though the former is recognized as a probably distinct division. This distinction in some cases is based upon real or assumed non-conformability.

THE terms conglomerate, agglomerate and breccia have distinct and different meaning. Conglomerate refers to a rock mass composed of rounded, water-worn pebbles, cobbles and sand, deposited usually under water, either on a shore line or in the bed of a river. Conglomerates are usually cemented by silica, lime, iron or some other mineral, forming a compact mass. This kind of rock is also called pudding stone. Agglomerate has reference to an unstratified mass of volcanic material, angular or water-worn, cemented by finer volcanic debris. Breccia is a rock made up of angular fragments, differing only in this respect from conglomerate. It may be composed of any kind of rock, or of many kinds. Amygdaloid has no relation to rocks of the kinds above mentioned, and is not a fragmental rock, but a volcanic rock in which air has formed spheroidal cavities. These are often found drawn out into almond shape by a stretching process, due to movement in the lava when cooling. These air vesicles are often found filled with calcite, quartz or zeolites.

SWELLING ground is not confined to slates alone. Some igneous rocks swell upon exposure in mine work-

ings. Experience has shown that the best way to keep drifts and other mine workings open in swelling ground is to timber heavily, spreading the legs of the sets widely at the bottom, and to "lag open" in order that the swelling ground may find an easy passage through the spaces between the lagging. This method also admits of cutting away and removing the encroaching ground, thereby preserving the main members of the set in their proper position. It has been found that almost every attempt to close lag ground of this character has resulted in bending and breaking the lagging and in forcing the legs of the set out of place—often breaking or crushing the timbers. Large timbers offer little additional resistance over small ones in swelling ground. The bottoms of levels have frequently to be cut down when in ground of this character. Swelling ground is one of the greatest sources of expense in mines on the central gold belt of California, though in some of them it is unknown.

REPLYING to a question from Silverton, Colo.: Where a millsite A has been subsequently encroached upon by the lode location B, and patent issued to B, unless it was expressly stipulated in the patent that the triangular section a b c was excepted, the locator loses that portion of his millsite. As long as A remains unpatented the tract really belongs to the public domain, though held under possessory title by the locator, and it is the opinion of prominent legal authority that the discovery of mineral on a millsite, by accident or otherwise, would make A subject to location as a lode claim, or be included within such. The statutes are not very explicit as to millsites and there are no precedents in a case such as that submitted. The law, however, does not permit one to enter upon the premises of another (as a millsite) for the purpose of discovery or location, but should the discovery be made outside the limits of the millsite and a claim located covering said site, it is believed the courts would sustain the lode claimant. In grading on a millsite or lode claim for the owner, the discovery of mineral by the workmen does not entitle them to the vein or deposit discovered, it belonging to the owner.

SALINE lands upon which there are salt springs, and deposits of rock salt are not subject to entry under the mining laws. The policy of the Government since the acquisition of the Northwest Territory and the inauguration of the federal land system has been to reserve saline and salt springs from sale. The object of this reservation was to preserve them for the future States, and they have never been disposed of, excepting under specific acts of Congress. By an act of January 12, 1877, some of the States upon their admission to the Union received grants of certain quantities of saline lands, to be selected within a stipulated time. The act provides for their sale at public auction at the rate of \$1.25 per acre, or at private sale at the same minimum rate in the event sales are not effected at public auction, but the operation of the act is confined to States which have had grants of salines which have been fully satisfied, or under which the right of selection has expired by limitation of time. The act, therefore, does not apply to the Territories; nor does it apply to Mississippi, Louisiana, California, Nevada, North and South Dakota, Montana, Washington, Idaho, Utah or Wyoming, none of which have received such a grant of land. Saline lands cannot be located under the desert land act. Tracts of land returned by the surveyor-general as saline may be shown to be agricultural in character, and will then be subject to entry under the agricultural land laws.

THE pumping system outlined by the Wallace, Idaho, correspondent is practically that in successful operation by application of a pneumatic principle at Cambria, Wyo., where the Cambria Mining Co. lifts a column of water 1850 feet in one straight lift. At a depth of 2300 feet a well or shaft, sunk to secure increase of water supply and for prospecting purposes, struck a stratum of water that rose within 200 feet of the surface. Two thousand feet of inch pipe were procured, the larger casing in the well replaced by a 4½-inch casing. The inch pipe, after connecting with the high pressure compressor, used in the haulage system underground, enters a T-joint at the top of the well, flowing down inside the casing 1700 feet from the surface, this air line being reduced near the bottom to ½ inch, lower and turned upward and drawn out to a ½-inch opening, forming a nozzle through which the compressed air enters entrance under average pressure of 900 pounds from the compressor. When the air was turned on there was a column of water from the 1700 up to the 200-foot level, and it took about fifteen minutes for enough pressure to gather in the empty air line and at the bottom of the well to start this column of water in motion. The back pressure at this point on each square inch was equal to the weight of a column of water 1 inch in diameter and 1500 feet in height, or 645 pounds per square inch. The air pressure at 900 pounds is about twice the back pressure of the weight of the water, so that when once in motion it rapidly raises the 1700 feet in the well and the 150 additional feet to the reservoir on the hillside at a rate of 1000 gallons per minute, which is not steadily maintained because the well can not supply more water at the same rate. After the first rush of water the well flows intermittently—first a short column of water, then a discharge of air. The rapidity of the flow is regulated by the size of the opening admitting the air. Two orifices are used—one ½ inch, which gives a flow of 120 gallons per minute, another ¾ inch, which raises the discharge to 200 gallons.

Some Data Requisite for Mining Reports.

Written for the MINING AND SCIENTIFIC PRESS by
W. L. WATTS, E. M., Los Angeles, Cal.

Many people think it is an easy thing to find a good mine, and many are willing to risk their money on the report of some one "who is supposed to know," who has just looked at a mine, taken a few specimens therefrom and had them assayed. It is astonishing that people will accept very meager evidence concerning mines and invest thereon, and yet they carefully study and weigh every fact before investing in any other enterprise. The general result of credulity in mining ventures is failure, and this hurts the mining industry.

The first thing to be considered about a mining proposition is: Is it a mine or a prospect? If it is a mine, is it one from which ore can be profitably extracted? If not, all suggestions as to its being made to pay by farther development should be very carefully scrutinized. If it is a prospect, it must be borne in mind that its value is prospective, and that such value is very much less than that of a mine in which the dimensions of a remunerative ore body have been ascertained. As far as circumstances will permit, a report on a mine should cover the following points: The topographical and geological features of the mine and the district in which it is situated, and the character of the mineral deposit, both with regard to its structure and composition. The report should be accompanied by maps, cross-sections and photographs, showing the dimensions of the property, the topography, workings above and under ground, the structure, and the known and probable extent of the ore body. Average samples of the ore body and of the different materials composing the ore body should be taken in a sufficient number of places and carefully assayed. If the ore is free-milling, the relative value of the free gold and sulphurets should be given. In the case of other ores, there should be an analysis showing the composition of the ore, and the metallurgical process most suitable for treating it should be designated. In the case of smelting ores the question of fluxes must also be dealt with, and not only the analyses of the ores, but also of available deposits of limestone and iron, must be given. The cost of labor, fuel and transportation, the supply of water and timber and the climatic conditions must be gone into. Moreover, the probable output of ore and the cost of mining and treating the same must be set forth. Lastly, the history of the mine and the title should be carefully considered, and the record of mines should receive attention which are situated on the same lead as the mine under investigation, or nearby, and in a similar formation to the mine reported on. In cases where the limited amount of development entitles a proposition to be classed only as a prospect, as many as possible of the points mentioned should be dealt with and especial regard should be paid to geological details. It is often expedient to make a preliminary reconnaissance of a mining property before examining it in detail; but it is unwise to invest in a mine without an extensive examination of the same, and, if practicable, having a mill test made on a large quantity of the ore. In the case of placer mines, a contour map of the territory should be made and the probable course of the channel or channels should be delineated. Wells should be sunk to bedrock, and sufficiently close together to demonstrate the general character of the gravel. Most of the wells may be drilled; but some of them must be dug, in order that the character of the bedrock may be ascertained. The material taken from the wells should be carefully washed, each sample speaking for 3 feet in depth; all changes in the character of the material should be carefully noted, and different materials should be washed separately. Results should be given in values per cubic yard; the available water supply at different seasons of the year; the heads that can be obtained; full information concerning dumpage, existing ditches and flumes, and the possibility and cost of making others should be clearly set forth.

With regard to oil lands, the main questions are: 1. Is there a known oil-yielding stratum that is likely to form an "oil line" through the territory to be examined; if not, is there a probability that such an oil-yielding stratum will be discovered by drilling? 2. What are the topographical conditions bearing on the conveyance of the oil by pipe line? 3. What is the character of the oil? The first of these questions can not be answered without a competent knowledge of the geology of the territory to be examined, and a report thereon should be accompanied by a map and cross-sections, showing the relative position and the structure of the geological formations, as far as the rock exposures furnish the requisite data. If there is a known oil-yielding stratum, its course through the territory investigated, and the probable width of the oil line it is likely to form, should be delineated. The best location for wells should be shown and the depth to which it is advisable to sink them should be stated. When practicable, the character of the oil should be de-

scribed, and the gravity of the crude oil and the products obtained by its fractional distillation should be set forth. If it is a question as to whether or not there is a probability of an oil-yielding stratum being discovered by drilling, it might be necessary to examine a large area around the territory immediately under investigation, and to make a reconnaissance map of the same before any conclusions of value could be arrived at as to whether or not it was likely an oil-yielding stratum would be discovered by drilling in the territory reported on. If the opinion is in the affirmative, the points at which it is considered advisable to drill prospect wells should be shown on the reconnaissance map and the areas that such wells would test should be delineated.

In all reports definite reasons should be given for any opinion expressed. It is evident that, although the element of risk is inseparable from all mining enterprises, it is greatly diminished by competent and careful preliminary work.

Mill of the Melones Mining Co. at Melones, Calaveras County, Cal.*

Written for the MINING AND SCIENTIFIC PRESS by
WALTER W. BRADLEY.

The most prominent addition to the milling facilities of Calaveras Co., Cal., during 1902 was the completion of sixty stamps in the mill of the Melones M. Co. The plans call for 120 stamps, of which the west half have been in operation since April 1st, 1902. The mill is on the north bank of the Stanislaus, at the point where Coyote creek comes into the main river, at Robinson's Ferry.

Water for power is obtained from the Stanislaus and brought from the dam 4 miles above the mill in a flume, 8 feet wide and 4 feet deep, having a capacity of 5000 miner's inches. From the end of the flume the water is carried under the mill in a 6-foot redwood stave pipe, 726.45 feet in length. Fig. 1 shows a section of this pipe, and gives a comparative idea of its size, arrangement of the staves, spacing of the hands, and the saddles for supporting it. A tunnel, 11'x11' in the clear, is driven from the edge of the river, 313.15 feet, to a point directly under the center of the mill. It is timbered with 16-inch square timbers, the sets being 5 feet apart. The water pipe is supported from the caps in "U" hangers. The water discharges along the floor of this tunnel. In a chamber at the bottom of the vertical shaft connecting this tunnel with the mill is a 27-inch Victor turbine wheel which transforms the energy of the water (under a 58-foot head) into effective power. The power is carried up into the mill by a vertical shaft, 40 feet 3 inches from top of wheel casing, and changed to the horizontal shaft by the bevelled gearing seen in Fig. 2. The teeth in the gear on the horizontal shaft are hard maple. The vertical pipe showing on the left of the picture contains a standpipe, inside, which is connected into the water pipe in the tunnel below, acting as a safety valve in case of sudden shutting down of the gate in the turbine. The standpipe also serves to indicate the water level in the penstock. The wide faced pulley on the farther side of the bevel gear is belted to the main line shaft running the west sixty stamps; and the one on this side is to drive the east sixty, but is at present belted to a countershaft driving the pumps, and a 150-light dynamo for lighting the mill and office buildings. The outside pulley on the west end of the jack-shaft drives an Ingersoll-Sergeant, five-drill compressor located on a level with the vanner floor below. The pulley in the foreground drives a 135 H. P., 250 volt, multipolar generator, which furnishes power for the electric railroad in the main tunnel. Both of these outside pulleys are connected with the central portion of the shaft by friction clutches. Since the photograph (Fig. 2) was taken, another pulley has been keyed onto the end of the shaft in the left foreground, to drive a double acting, duplex, Giant compressor—the smaller compressor proving inadequate to meet demands of machine drills. The air is carried to the mine from the mill through a mile of 6-inch pipe, up over Carson hill to the top of the Reserve shaft. A branch line is also laid in the main tunnel to the breast on that level. The rock broken in the upper levels is dropped through a chute to a bin on the South Carolina tunnel level; there trammed in 1½-ton cars, six cars in train pulled by a horse for 550 feet underground; dropped 220 feet, vertical, to a bin on the Melones (main tunnel, or 1000-foot level); then trammed out 4700 feet in four 8-ton cars in train by electric locomotive to the outside storage bin above the mill. From here the rock is trammed 150 feet to the mill and dumped into the rock breaker, and distributed to the mill ore bin below by car. There are two No. 5 Gates rock breakers set side by side. These may be used together or singly, the grizzlies being arranged to send half of the rock to each breaker when required.

Fig. 3 shows the cam shaft floor looking toward

*See Illustrations on Front Page.

the center of the mill. In the background, at the end of the ore bin, can be seen the top of the 30,000-gallon water tank for batteries and concentrators. The Canda self-locking cams are used. The order of drop is 1—5—2—4—3. The guides for the stamp stems have wood bushings of seasoned maple in iron frames. With the horizontal geared power shaft running 198 revolutions per minute, the stamps have a speed of 106 drops per minute. Prior to November 1, a considerable portion of the rock handled was the oxidized ore from an open cut at the top of the hill. Starting with a 7-inch drop, 108 drops per minute, a 6-inch discharge (chuck block being used), and 24-mesh iron wire screen, trouble was experienced with the mortars filling up by the screens becoming clogged with splinters from the roots, chips and hits of wood accompanying the ore. There was often a very bothersome amount of roots in this surface ore. Then the chuck blocks were discarded, the drop lowered to 5½ inches and the speed to 104 drops. By taking out the chuck block the height of discharge varied from ½ inch to 3 or 4 inches, as the dies wore down. When the dies became that low an extra set of false dies was put in and used till the regular dies were worn out. This low discharge prevented the chips collecting and floating on the surface of the water and so clogging the screen, and kept them so well agitated that they were thoroughly pulped and passed through the screen readily. The mortars in this mill are the narrow type known as the "Utica fast crushing mortar," with liners. An average of four to five tons of ore per stamp are crushed daily. The ore feeders are of the Challenge type. The arrangement of the plates is shown in Fig. 4. They are divided plates, 25 feet long, and have an inch step half way down. Originally they were set at a grade of 2½ inches per foot; but, after running a while, the grade was changed to 1½ inch per foot by blocking up the lower end, as they were considered too steep for the character of ore being handled. The engraving shows the plates of the middle twenty stamps not yet raised. Hanging from the timbers overhead immediately in front of the battery posts will be seen a steel rail. On this rail runs a hanging platform for transporting battery cleanup sands and broken shoes and dies to the cleanup room at the west end of the mill. In the cleanup room, besides sinks, bench for repairing screens, rack for screen frames and chuck blocks, etc., are two cleanup harrels and a three-hall amalgam grinder for cleaning the amalgam.

As intermediates, between the main line shaft and the lines driving the concentrators, are two pairs of cone pulleys, one for the tables and one for the belt machines. These cones are 7 feet long, 24 inches diameter at large end, 20 inches at small end, and by them the speed of the concentrators may be varied as conditions demand (i. e., change in speed of motor or changes in character of pulp). The stamps, the tables and the Frues have their separate speed indicators. The floor on which the tables are located is between the silvered plates and the vanners. There are twelve of these machines (one for each five stamps), nine Wilfleys (seven with the elevator and two without), two Hallett stratification tables and one Woodbury improved. Fig. 5 shows two of these tables, the one nearest having the elevator attached. The tailings from the tables are run over the Frues, one-half over each of two. Because of this it was found necessary to use the clear water on the tables sparingly, as otherwise the belt machines would have more water than they could handle and do good work. The Wilfley and the Hallett tables require a speed of at least 240 revolutions per minute to give a reasonable degree of separation of the sulphides from the rest of the pulp. By running them at 250 or 260 revolutions the grade can be flattened, less clear water used and a better separation obtained. With this arrangement it was found very convenient to put on the lower corner of the table, about on the line of separation between the sulphides and the other materials, a pivoted redwood "pointer." By this the amount of "sand" allowed in the concentrates could be changed slightly without altering the grade of the table or the water supply. The Woodbury table requires 20 to 25 revolutions per minute more speed than the others. The tables catch the major portion of the sulphides, and what fines escape them are caught on the belt machines below (Fig. 6). These are of the Frue style, 4 feet wide, and are run at 200 revolutions per minute (180 being the minimum at which they will do reasonable work). The tailings are run into the river at the mouth of the mill tunnel, where there is an automatic sampler. The raw concentrates are treated by agitation cyanide process direct.

No SELF-CONTAINED furnaces for treating cinnabar ores, having a capacity of twenty to thirty tons daily, are made, excepting the well-known type of brick furnace in use in California. Retorts are manufactured of iron for the purpose of retorting amalgam, and in these ores of quicksilver may be treated, but nothing except high-grade ores could be handled profitably in these retorts, as their capacity is limited and they are rapidly destructible. What is known as the continuous-feed furnace, which is the only economical furnace made, is built of brick.

Stamp Milling and Amalgamation of Free Gold Ores.

NUMBER 11.

Written for the MINING AND SCIENTIFIC PRESS by DANA HARMON, San Francisco, Cal.

WOODEN MORTAR BLOCKS.—If wooden mortar blocks are used, make them long—12 to 14 feet—set on solid foundation. Ram with concrete on sides and ends of pit. This concrete should not be continuous all around the block. There should be an open space about 16 inches long on each side (but not on the ends) leading to the bottom of the pit; these spaces to be filled with dry sand, or tailings run in. There is no better preservative to wooden blocks than constant wetting, and these sand pillars insure thorough saturation of the wood.

By no means is it a sine qua non that the natural foundation be solid rock. If a hard rock bottom does not exist at the site, then thick concrete, with plenty of base area, must be provided. With a spongy bottom you will be safer by first driving piles for the concrete base to rest upon. Even with a natural hard rock floor in the bottom of the pit, there should be a layer of concrete 10 to 12 inches thick, for the reason that natural rock floors almost invariably have weak spots—they lack the essential quality of homogeneity. Make this floor concrete in two batches—first the ordinary mixture of sand, cement and rock; next a couple of inches of sand and cement to bring the floor to a level.

Now prepare a frame of 1x4 battens the exact size of the base of the mortar block. Set the edges of the frame on a bevel and chamfer the base of the block to exactly fit the concrete cap formed by this frame. Wedge this frame securely on the floor of the pit and then fill in around the edges of the frame and flush with its top with cement mortar. When this has well set remove the frame and you will have a smooth concrete cup to receive the mortar block. Into this cup sprinkle a hedding 1 inch thick of clean, sharp, sifted, fine sand. The advantages of this cup are obvious. Its bevel edges guide the block exactly to its true position. Dirt tamping is had; concrete is the best, and next to that tailings run in.

FIG 1.

The wood must be sound, solid and free from sap and wind shake. If bowed by band or sawed at a mill, examine the log before dressing. On the Pacific coast, yellow pine full of pitch, or heart sugar pine, or hard Mendocino redwood make excellent blocks. If a solid block is used, i. e., two blocks bolted and keyed together, the two halves should both be butt cuts, so as to secure homogeneous setting. The question is can we at reasonable expense preserve the outside of the block from rot, for it is the outside that holds the mortar bolts. Tar is not good. Creosote seems to be out of the race because it must be forced into the pores by pressure. Even then, the depth to which it will penetrate depends upon the hardness of the wood; even in some pine woods it can not be forced to the center of a 4-inch plank. The method narrows to the slacked lime treatment, or to painting with some such hot preparation as paraffine, or avenarius carbolineum. The paraffine can not be used on mortice and tenon joints because it is too viscid and sets too quick. Carbolineum is readily absorbed and is excellent for such joints. It will not add much to the expense to dig a pit and dip all the foundation timbers. Three men will handle a mortar block with a hydraulic jack. A bot dip is so superior to hand painting that it is worth its increased cost. Mortar bolts are usually about 30 inches long; they should be longer, say 42 inches.

A first-class mortar block can be built up of plank 2 to 3 inches thick, well saturated with paraffine or carbolineum, nailed and bolted together.

Mr. V. S. Garharini, a well-known millwright of California, uses the following ingenious method of lowering the mortar block into the pit. It avoids the use of a high gin pole or tripod, and delivers the block squarely into the pit. He fully dresses the block before lowering it, pockets, top, bottom and sides. The bottom of the pit is carefully

prepared and the blocks drop into the exact spot. The battery frame and ore bin timbers are first set up. The block is then rolled into position in front of the pit, tipped up to 45° angle by a hydraulic jack, and then brought vertical between the posts by a light tackle block; a 12x12-inch is thrown across the top of the battery posts to carry on chain blocks the weight of the block while the lagging is being uncovered from the pit; the line sills are now keyed tight against the block, which is then quickly lowered by easing off on the line sill keys; the block slides into place gently, being held by skin friction against the sills. The method is a great improvement over the old gin pole style, wobbling a block awkwardly into the pit and finally landing it in that exasperating spot almost but not exactly where you want it, with two or three loose pebbles underneath.

GUIDES.—Use the individual iron guide—guides without the wood bushing.

The stem will not be excessively worn by rubbing directly against the cast-iron guide with $\frac{1}{16}$ of an inch play on either side. Oil sparingly, by just touching the stem with waste moistened with a good quality of machine oil.

There are iron guides with wood bushings; but I have never seen one worth buying. The cap piece should be made of malleable iron and not of cast iron, and the bedpiece should be 2 inches thick to avoid breakage.

The cap bolts should not go clear through the girt, but should be arranged so that they can be readily replaced. Breakage of bolts is unavoidable, therefore renewals must be promptly made.

Competition brings the foundryman to manufactur-

WARMTH OF BUILDING.—The plate and concentrator rooms should be built so as to be warm in winter season. Never have a draughty mill. Icicles kill plate amalgamation. A few dollars spent in tarred paper on the walls will be a wise investment in cold countries. A generous stove set on the bottom floor with 11-inch smokestack and a couple of bot air drums 10 feet long by 30 inches in diameter will prove economical of wood and keep a 20-stamp mill building comfortable and fit for amalgamation. Lay a few 2-inch bot water pipes on the floor underneath the tables to keep the boards dry in winter season.

Light and warmth are not luxuries; they are necessities of the business.

TABLES.—Tables should be heavy and solid. Flimsy tables made of thin boards and light scantling get out of true. Figs. 2 and 3 show a table fastened to the floor which by my notion has advantages over the rolling table. Twelve feet long by 10 feet wide will suffice; 10 feet of this is nailed to the floor; the 30-inch apron is removable to allow setting in shoes and dies.

The frame is of three pieces, 4x6 inches by 10 feet, dressed on upper edge and notched down $\frac{1}{2}$ inch every 2 feet. The boards are $1\frac{1}{2}$ inch thick, 2 feet wide, 5 feet long, dressed on upper side, edges and ends. After dressing true, cross plane the board so that there shall be a fall of $\frac{1}{16}$ inch from ends to center. Each board is butted snug to the one next above it, and nailed or screwed to the 4x6-inch, the ends of the boards being flush with the outer edge of the outside 4x6-inch. The side rail is a plank $1\frac{1}{2}$ x10 inches nailed against the side of the 4x6-inch and

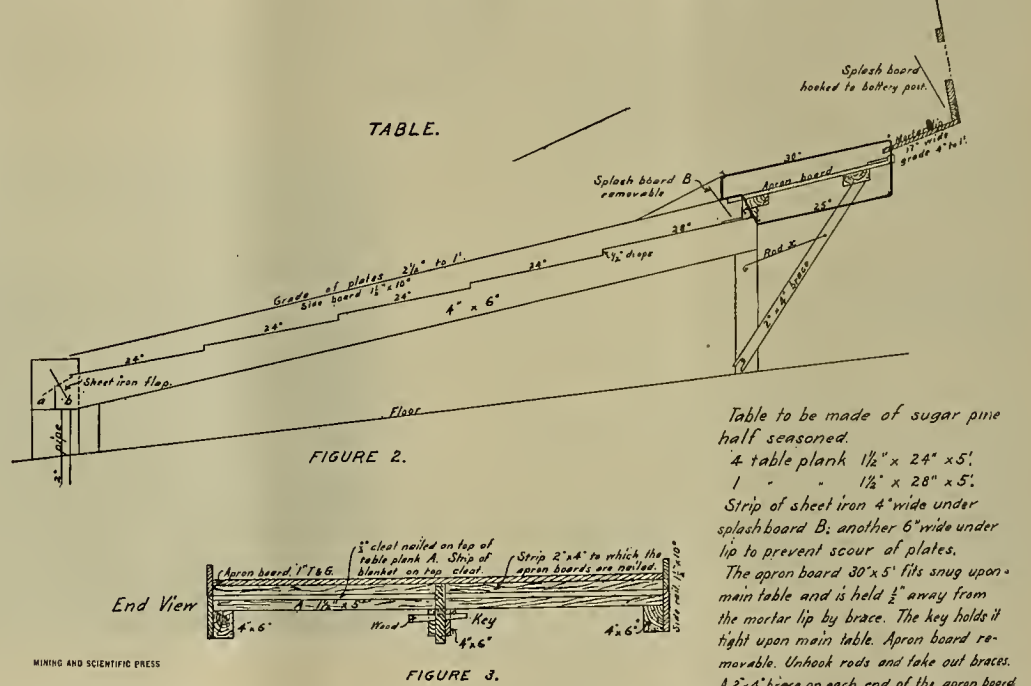

FIGURE 2.

FIGURE 3.

Table to be made of sugar pine half seasoned.

4 table plank $1\frac{1}{2}$ " x 24" x 5'.

1 " " $1\frac{1}{2}$ " x 28" x 5'.

Strip of sheet iron 4" wide under splashboard B; another 6" wide under lip to prevent scour of plates.

The apron board 30" x 5' fits snug upon main table and is held $\frac{1}{2}$ " away from the mortar lip by brace. The key holds it tight upon main table. Apron board removable. Unhook rods and take out braces.

A 2"x4" brace on each end of the apron board

ing a cheap iron guide—the very lightest salable—but the buyer had better pay for more cast iron and for malleable caps.

With the old-fashioned oak guides there is too much friction, too much wear from burning—in a few months the shoe won't center on the die; too much loss of time when turning stems.

With the individual iron guide the stems will keep cool. With the oak guide the stems are always warm and often hot. Heat means friction.

SCREENS.—Before deciding upon any screen try a variety. I prefer the tin costing $\frac{1}{4}$ cent per ton crushed, the hurr inside. Neither Russia iron, brass wire nor steel can compete with this. Put strips of $\frac{3}{4}$ -inch wide of $\frac{1}{2}$ cheap rubber sheet packing between the tin and the wood frame and you will at least double the life of the tin screen. Before using, burn off the tin over a clear forge fire—just heat to redness, keeping the screen moving to and fro over the fire—this anneals and toughens the iron. I would emphasize the importance of this.

The three commercial sizes are: No. 0 = No. 8 needle; 441 holes to square inch. No. 1 = No. 7 needle; 324 holes to square inch. No. 2 = No. 4 needle; 225 holes to square inch.

No. 3 is too coarse for quartz.

If manufacturers would punch a size between the No. 0 and No. 1 and also a size a trifle coarser than No. 2, the range of tin screens would cover nearly all cases of quartz milling. The screen should have a selvage finish at both ends. It will be found that the perforations in a narrow screen (selvage both ends) will be more uniformly spaced than in the large sheets. Unless watched, the manufacturers will ship a box of 10x14-inch cut from large sheets—rarely a selvage edge.

LINERS.—Mortar liners removable at cleanup. The main hack liner instead of being in one piece should be cut so as to give a lower piece of same width as the front liner.

forming a tight joint against the ends of the boards. To prevent leaking, bruise the edges of the boards with a blunt chisel, the blade 2 or 3 inches wide and $\frac{1}{4}$ inch thick. As soon as the table is wet these bruises swell. A $\frac{1}{2}$ x1-inch strip holds the coppers down and completes the tight joint.

At foot of table a double drain box with sheet iron flap. While the mill is running the pulp flows into box (b), thence to concentrators through a 2-inch pipe, the end of the pipe projecting $\frac{1}{2}$ inch above the bottom of the box (b)—thus forming sufficient quicksilver trap. When brushing up, the flap is lowered and the washings go over into box (a), whence they overflow through notches into box (b).

These double drain boxes will, under careful milling, recover \$25 to \$50 per month in amalgam which would otherwise be swamped in the concentrates or lost in the canyon. Under slipshod milling this box catchment might easily pay the mill payroll. This is for twenty stamps.

Fig. 2 shows the splashboard arrangement. By using a lip plate 17 inches wide, set on grade of 4 inches to the foot, there will be no clogging with sand and sulphurets, and its amalgam catchment will be heavy. Foundries will ordinarily cast a mortar with $1\frac{1}{2}$ inch to foot grade on the lip. This will surely clog and prevent the amalgam from catching on the lip plate.

Let the pulp drop from the mortar lip (usually $1\frac{1}{2}$ to 3-inch drop) upon a sheet iron strip 6 inches wide, whence it flows upon the copper plate. A drop of over $\frac{1}{2}$ inch will scour the silver. Under the splashboard B is 4-inch strip of sheet iron over the plate to prevent scour. A plain 3-inch wide splashboard receives the pulp from the 17-inch lip and prevents too rapid rush upon the apron plate.

There is no objection to using a quicksilver trap at the end of the tables, except this, that the millman will be apt to lean too hard on the trap. If any trap is used the type in use at the Black Hills mills is per-

haps the best, 8 inches wide by 10 inches long, with three sliding iron partitions inside, 18 inches deep on inlet side and 6 inches deep on outlet side.

LAUNDERS.—The V-shaped wooden launder has the advantage over 2-inch pipe of not clogging. Set on grade of $1\frac{1}{2}$ inch per foot. Make the box 1x4 sides set on top of 1x6 bottom, then nail strips inside to form the V.

ROCK BREAKERS.—Upon nearly all quartz or hard ores the mill should have two rock breakers, coarse and fine. Set the jaws of the coarse breaker 4 inches apart, so that a sledge can slide through, thereby avoiding the breaking of the pitman or side rods. Dump all the ore, coarse and fine, going to the mill, directly into this large breaker. The mixing of fine with coarse prolongs the life of the jaws. All the ore that is crushed in the large breaker goes to a grizzly—the fines going to the feeders, the coarse to be crushed in a second breaker. Manganese is the most durable material for mortar liners and rock breaker jaws.

GRIZZLY.—Grizzlies often give much trouble by clogging—the rock begins to build against the timbers. The most satisfactory that I have ever used is made of twelve or sixteen-pound T rail, downside up, bars 6 to 8 feet long, $1\frac{1}{2}$ inch apart, at an angle of 42° to 45° , the lower end of the rails rolled over, thus:

(See Fig. 5.) If not over 8 feet long, it will be unnecessary to use a middle bar with its thimbles. The steep grade will give a fine product—there will be only occasional clogging.

SKYLIGHTS.—Nearly every large mill is dark in the middle; none need or should be. Builders depend too much upon side wall windows. One skylight in

the roof is better than four side wall windows. Fig. 4 shows a cheap skylight set flush with the shakes which I have used successfully even in heavy snow countries on half pitch roofs. The glass was ordinary twenty-one-ounce plain. It does not leak and the snow slides over it. Whitewash walls and ceiling. Have a well lighted mill day and night.

(TO BE CONTINUED.)

THERE is always more or less friction in moving mine cars, particularly underground where the increased friction and resistance is due to dirt on the rails. It will be found that the resistance on properly constructed tracks, those having uniformity of gauge and carefully tamped, offer much less friction than those that alternately spread and pinch the wheels of the car or sag beneath its weight, requiring the trammer to constantly push the car up-grade. It is economy to lay good tracks with a grade suited to the traffic. Five inches in 100 feet is a normal grade on a straight track, but the grade on curves should be more, as the resistance is greater. The gauge should be slightly wider on curves than on the straight portion of the track. Well oiled wheels are indispensable to light-running cars.

The Terlingua Quicksilver Deposits of Texas.*

NUMBER II.—CONCLUDED.

Written by B. F. HILL, Geologist.

HANDLING THE ORE.—After being taken from the openings the ore is sorted by hand. The fine material, which is often abundant, is tested by means of washings in the horn spoon. The ore is put into piles according to richness and transported to the furnaces by means of wagons drawn by mules. The haul is often over a mile and the roads are bad. The installation of trams or cables would seem to be desirable in some of the workings.

The ore wagons discharge their loads either on the floors of the crushers or in piles from which it is taken by wheelbarrows to the crushers.

THE PLANTS.—The crushers used at both reduction works are of the Blake type of jaw crusher. They have capacities greater than the furnaces, and it is necessary to run only a few hours of the day. The crushers are operated by Fairbanks-Morse gasoline engines. The crushed material is carried by belt conveyors to the ore bins. From these bins, which are above the level of the top of the furnaces, the ore is taken through chutes into cars of a cubic yard capacity. The ore put into the furnace at the top descends and is burned. The spent ore is drawn from the base of the furnace into iron cars and dumped into the canyons.

THE RETORTS.—Although at present all the quicksilver produced in the Terlingua district is from continuous furnaces, when the field was first opened a considerable quantity of metal was produced from

years of experimental work in quicksilver reduction. The furnaces employed have been evolved with much labor and expense, and it has been possible for the Texas miners to attain good results without passing through the long and expensive experimental stages. The scarcity of water has made it necessary to cool the condensers by air entirely, and has also been prohibitive of allowing the fines to be made into "adobes."

In general, the furnace utilizes a series of inclined shelves placed in the opposite walls of narrow, vertical shafts. These shelves retard the descent of the columns of fine ore. The shelves are inclined at an angle of 45° to the walls, and each shelf is, therefore, perpendicular to the next lower one in the opposite wall.

Ore fed into the furnace from the hopper at the top runs from one shelf to the other until it reaches the bottom, when it forms a continuous zigzag column of ore from the top to the discharging apparatus. The end walls of the ore chambers are pierced with rectangular openings, allowing the flames to pass from the fireplace through the ore on the shelves to the vapor chamber, and from there they pass into the condensers. Arches over the firebox and across the vapor chambers cause the air and fumes to make four passages across the furnace before going into the condensers. The arches cause the air that enters the fireplace to be drawn through roasted ore, thus heating the air and absorbing quicksilver vapor from the ore. Then the hot products of combustion pass through the partly roasted ore, raising its temperature, and then pass back and forth through the comparatively cold ore of the upper part of the chamber. This method has the advantage of heating the cold ore and cooling the hot fumes, which when they leave the furnaces for the condensers are only slightly above the boiling point of quicksilver.

The device at the base of the ore chamber for dis-

Fig. 2—Quicksilver Retort, Terlingua, Texas.

retorts, about ten of which were operated in various parts of the district.

The largest amount of quicksilver from retorts was produced by Lindheim & Dewees, whose plant was situated on Terlingua creek, 10 miles from the mines, as it was found cheaper to haul the rich ore to the wood and water. Here several hundred flasks of quicksilver are said to have been produced, the ore consumed having been very rich cinnabar. In fact, only the rich ore can be treated by the retort method, as the waste is great. The retorts were found to be short-lived and burned out rapidly, in spite of precautions taken to prevent it.

THE FURNACES.—The furnaces used in quicksilver reduction in the Terlingua district all belong to the same class of continuous furnaces. They are slight modifications of the Scott-Huttner furnaces used extensively in California, and were built by Robert Scott.

Three furnaces have been built—one of 40-ton normal capacity, belonging to the Terlingua Mining Co., and two 10-ton furnaces, belonging to the Marfa & Mariposa Co. The latter company have the condensers arranged in battery form, allowing the last four condensers of the eight to be used by both furnaces.

The New Almaden practice of separating the ore into classes of various sizes and richness, as "tieras," "granzas" and "granzita," is not employed at Terlingua. The ore has a large proportion of fine material in it as it is mined, and the large lumps are, as a rule, crushed to about 1 to 2 inches, which would place it in a class between the "granzita" and "tieras" of California. The average of from 1% to 3% corresponds also to the value of California ore of the class mentioned.

The operators in the Terlingua field have been fortunate in having the benefits of the results of

*Extract from Report of B. F. Hill in Bulletin No. 4, University of Texas.

charging the burned ore is arranged in such a manner as to allow the same quantity of unburned ore to enter the furnace from the hopper at the top as it is drawn from the bottom. In the 40-ton furnace the ore remains in the ore chamber thirty hours.

THE CONDENSERS.—The principles upon which the most successful condensers have been constructed are as follows: 1. Cooling of the furnace fumes by contact with large radiating surfaces exposed to the air. 2. Sedimentation of the condensed quicksilver particles in enlarged chambers where the velocity of the gaseous mixture is reduced. 3. Constant exposure to friction surfaces, cross-currents, and vortex motions to remove the globules of metal by calling into play the force of adhesion.

The condensing systems of these furnaces consist of brick chambers connected to the furnace by pipes. These chambers are tall and narrow, divided into compartments having openings about 2 feet square at the top and bottom to allow cleaning. These openings are closed by iron plates held in position by wooden bars across the front, and are made tight by setting with clay and ashes. The floors of the condensers, which are carefully constructed of cement, slope each way from the center to the sides, so as to allow the condensed mercury and acid water to be delivered to the side, and to facilitate the handling of the soot. Along each side of the condensers are inclined gutters of brick, about 18 inches deep and 9 inches wide, which carry the condensed mercury and acid water to receiving vats.

The condensers are built with air spaces between them to facilitate the cooling of the fumes. No water backs are used on the Terlingua plants, the cooling being entirely due to radiation. The fumes after leaving the furnace pass into the first condenser near the top, pass down the compartment on that side, thence through an opening in the partition wall into the other compartment of the condenser, up which they pass to be discharged into the next of the series

of condensers through iron pipes. These connecting pipes have valves to regulate the draft.

The plant of the Terlingua Mining Company has all the condensers, eight in number, arranged in a straight row. The first condensers are used as a dust chamber, and little or no mercury is obtained from it on account of its high temperature. Most of the mercury is obtained from the second and third chambers, while scarcely any is obtained from the last three. Between the eighth condenser and the smoke-stack an arrangement has been devised for increasing the draft through the condensers by means of a fire, thus pulling the gases along the line of communication between the condensers.

The plant at the works of the Marfa & Mariposa Co. is arranged somewhat differently. The two condensers next to each of the two furnaces in this case yield a great proportion of the mercury, with very little after the fourth or the first in the battery used by the two furnaces in common.

PRODUCT OF CONDENSERS.—The condensers, when cleaned, yield other materials besides the quicksilver, which are to be taken into account. Ore dust is invariably present in the first condenser—in fact, this condenser at the Terlingua Mining Co.'s furnace yields little quicksilver and is used for a dust chamber. Considerable quantities of ore dust beyond the first condenser furnishes evidence that the furnace is not working properly.

The whole series of condensers have the interiors coated with soot, which covers walls, roofs and floors. This soot is due to the unburned carbon and hydrocarbons from wood used as fuel.

Large quantities of quicksilver are mechanically intermixed with soot, the greater proportion of which is removed by mechanical treatment. The percentage of quicksilver that the soot carries depends entirely on the position of the condenser with regard to the furnace. The soot contains in the cool condensers large quantities of acid water, while in the hot ones it contains little or none. In the condensers remote from the furnace the soot is intimately mixed with acid water and becomes a black slime carrying small quantities of finely divided quicksilver.

In cleaning the condensers, the iron manhole at the base of the condensers is opened and the operator removes the soot that has accumulated along the lower walls and the floor, by means of a long hoe made of square pieces of thick rubber, supported by iron plates, the handle being attached at the center. The rubber is used to prevent wear on the floors and walls. The soot is drawn down the inclined floor to the manhole and is there kneaded back and forth with the hoe. This causes the quicksilver particles to cohere and run out of the soot into the channels leading to the receiving vats. Before reaching the vats, however, the quicksilver runs through settling boxes of wood and is filtered through charcoal. From the bottom of the settling boxes it flows through a goose neck into the vats. By this means it has been freed from particles of soot and acid water and is "dry" and ready for hotting. The operations from the gutter to the vat are conducted by gravity.

When the soot at the manhole has been worked until most of the quicksilver has been removed, the residue is taken from the floor and treated outside. When the soot on the floor is too dry to readily yield up its quicksilver, water is added; when too wet, dry ashes are added. From long experience, the workmen who are in charge of the "clean-ups" have come to recognize the exact amount of water necessary for the easiest working off the soot.

After the soot has been taken from the floor of the condensers it is placed on an inclined sheet-iron box, under which a fire has been built. Here water or ashes are added from time to time, as is necessary, and practically the same operation as was used on the floor of the condenser is gone through. The quicksilver that is freed from the soot goes down to the lower end and runs into a sheet-iron bucket. The residue of the soot from this method of working is charged back into the furnace. The waste from the soot, therefore, is insignificant, as it goes through the furnace time and again.

The operation of cleaning the condensers is carried on without interrupting the working of the furnace. Only one manhole at a time is opened and the inward draught is sufficient to prevent the escape of fumes.

The State Legislature of California has legalized a code of bell signals for mines and its use is compulsory. Any accident occurring through neglect to employ the State code makes the management of such mine responsible for said accident. A miner working in a locality where the State code is in use who goes to another district of the State where the State code is not employed is in imminent danger unless he at once familiarizes himself with the code in use in the latter district.

GRANITE, by the addition of hornblende, becomes hornblende granite, and by the disappearance of mica in the presence of hornblende becomes syenite. Andesite, by the addition of quartz, becomes dacite.

CRYSTALS of red copper oxide, when incrusting, sometimes resemble crystallized cinnabar, but the former is darker in color.

The Dry Ores of Slocan, B. C.

Written for the MINING AND SCIENTIFIC PRESS by
RONALD C. CAMPBELL-JOHNSTON, M. I. M. M.

The dry ores of Slocan are undoubtedly attracting considerable attention from the mining world for many reasons; partly that her veins contain large masses of ore; partly that the average values are abnormal, and partly as this class of ore calls for a new arrangement of metallurgical skill to recover at least the requisite 90% of contents.

To the unprofessional man the question arises as to what is a dry ore? In smelting gold and silver ores, sufficient base metals, such as copper, or lead, are required to carry the precious metals and to leave a clean slag to throw away in the first stage. Lead, being the most common conveyor used, when absent in an ore, or existing in less quantities than 10%, has to be added as a wet ore. Therefore a dry ore is one carrying precious metals, but is not self-containing as a lead flux, whereas a wet ore has sufficient lead in its composition.

The characteristics of the dry ores of Slocan are that the silver occurs native, or as sulphides, or alloyed. The gold is carried in arsenides and sulphides of iron, only being native visibly sometimes in the oxidized planes.

The structure of the district consists of ranges of eruptive granite with trend northerly and southerly, indented by past and present glaciers with their accruing rivulets eating into the smooth sides. The elevations vary from 9000 to 2000 feet above sea level, with a corresponding climate in snow and ample water power. Timber grows thickly to 5000 feet and then gradually dwarfs off to barrenness. Deep, narrow and long lakes lie parallel to the trend, with rivers forming level valleys as outlets, affording cheap methods of transportation and easy grades for railways. Mono-railways driven by electricity are proposed to connect the mines with the trunk transportation systems.

The veins running north and south have various consistent strikes, some east and some west of north, the different series making clean intersections. The granite when altered and softened by lime infiltration seems more favorable for ore. There are even later veins with east and west strike which shatter the earlier north and south veins at their junctions. Dikes of pegmatite and felsite occur, but seem, so far as explored, to be later than the veins in formation, and therefore have no effect on the other fissures, except taking their place when crossing them.

Between walls the veins vary from 125 feet to a few feet in some cases. In these veins the ore shoots lie parallel, come together and form large masses; or jump off to another plane, and so necessitate continual crosscutting, or stoping out everything between walls.

The vein fillings, outside the ore shoots, so often carry commercial values distributed throughout that their mechanical treatment is an object. The dip of the north and south veins is mostly to the east, but several examples of a westerly dip occur. The dip of the east and west veins seems to have an equal number of examples to the north and to the south, but with no connection to form synclinal or anticlinal veins, their characteristic contents being dissimilar. The values of the ore shoots when sorted for sacking sometimes give phenomenal results, but there are numberless shoots of ore from 100 to 1100 feet long, 60 to 500 feet deep on their axis, and 2 to 40 feet wide, proven to carry from 60 to 300 ounces in silver per ton and \$4 to \$40 in gold. The vein fillings carry ten ounces in silver and upwards, and from \$2 in gold upwards. The shoots occur in the mines at frequent intervals near intersections of veins. Three series of parallel veins have already been proven by work and natural exposures to continue in straight courses for 5 miles and maybe go farther.

Stoping and developing costs an average of \$2 per ton mined and less on large veins; wet concentration by jigs and tables 40 cents, with a 70% extraction; sacking and sorting, with price of sacks, costs \$3 a ton on the ore sorted, or say, 75 cents on the ore mined, allowing for one-fifth waste. Transportation by teams costs \$3 a ton. Freight and treatment at smelters \$9 a ton, with five ounces deduction for silver up to 100 ounces, and ten ounces per hundred deduction on surplus values.

The per ton cost of ore mined going five into one, can be seen from the above statement, and also that only ore shoots without waste can at present be handled.

The aim of the managers is to stop out the veins from wall to wall, to mechanically treat the whole hulk in order to concentrate the values, and yet recover 90%. On the sulphides below water level jig and table concentration, followed by the Elmore oil process, is proposed. The oxides which constitute a large tonnage have then to be left untreated. Others propose to cyanide the ores in hulk after concentration. The cost of treating slimes by filter presses, or converting the sulphides into chlorides to ensure

successful solution by the Phoenix or other process, allows only the richer ores to be treated.

Dry concentration stares one in the face as the primary solution, and this is a process to treat material as fine as 80 to 200 mesh when classified, since these fines occur in all crushings.

Local facilities for fuel, fluxes and ample power are abundant. With an economical concentration the gold and silver ores of Slocan are rich enough to continue being profitably produced, despite the even lower price of silver.

Slocan, B. C., Jan. 19, 1903.

Mining Manganese in Colombia.*

G. E. G. WILLIAMS, Colon, S. A.

Manganese ore has been found upon the isthmus of Panama throughout a region of nearly 300 square miles, over the greater part of which, however, it is known only in small bodies without commercial value.

The ore occurs as oxide, chiefly the variety psilomelane.

The Soledad mine is the most important in the region.

The first discovery here was of large and small boulders of manganese ore scattered over the westerly and northerly slopes of the Soledad mountain. The boulders were all upon the surface, or at slight depths below. The surface soil was yellow clay formed from the decomposition of a shale. In shallow excavations the clay became harder, and the original lines of stratification were usually visible, although the decomposition extended to a much greater depth. The boulders of manganese were invariably contained in the decomposed surface rock, and extended investigation failed to show any ore in the lower strata.

The Soledad ores comprise braunite, pyrolusite and psilomelane—principally the last. The greater part of the ore is massive, varying in color from a steel gray to a bluish black, and usually showing a conchoidal fracture. It is rarely stratified; but there are some bodies of interstratified soft ore and clay. Pockets of ore, soft enough to be mined without explosives, are occasionally, but not often, found in the massive ore.

Besides high-grade bodies, there are large bodies of siliceous ore carrying about 47% of manganese, and from 18% to 30% of silica. These are not worked at present, but will undoubtedly be utilized hereafter, since the greater part of silica is not in chemical combination with the ore, and can be removed by crushing and jigging. The percentage of phosphorus in these siliceous ores is always under 0.075.

METHOD OF MINING.—The discovery outcrop is about 100 feet below the summit of the hill. An open cut was begun about 20 feet below the outcrop and carried in until the walls were 100 feet high. The mountain, rising faster than the ore body, gave a constantly increasing over-burden to remove; and this, with the difficulty of holding the side walls, led to the abandonment of open-cut work and the beginning of underground mining in 1898. A tunnel was driven into the ore body from the open-cut level, and from the same level a shaft was sunk 110 feet and two levels were opened. The mine is drained by a tunnel on the bottom level connecting with the shaft.

The ore is usually stoped for the entire width of the deposit, both heavy timbering and supplemental filling being required. At some points it is necessary to leave pillars of ore in place, to be extracted when the stope is about to be finally abandoned. The ground is difficult to hold, because of the decomposed rocks surrounding the ore and the large masses of clay associated with it. Occasionally a pocket of clay is opened which is under heavy pressure from the surrounding rock or ore. As soon as an outlet is furnished, the clay begins to flow into the stope in a plastic mass; and great difficulty is often experienced in checking this flow. The most satisfactory method of working—indeed, the only one by which the soft clay walls can be held—is to keep the stopes filled to within about 7 feet of the roof. The ore shoots and man-ways are built up from the level below, as the filling is carried up. The material for filling, apart from what is furnished from waste in the mine, is obtained outside, on the open-cut level.

Square-set timbering has been used in large stopes, but it has been found better and cheaper, where the filling system was employed, to support the roof with cribs of round logs, which accommodate themselves, without damage, to the shrinkage of the newly filled material and the pressure from the ore.

The ore from the lower levels is hoisted to the open-cut level by a gasoline hoist, which was installed on account of the difficulty of obtaining a supply of water through the dry season.

The ore is hand picked on the open-cut level, the large pieces going direct to the tramway which connects the mine with the railroad, while the small pieces and finely powdered ore are transported separately, taken to the log washer, and screened after washing.

The size above 0.5-inch mesh is hand picked and

* Abstract from Transactions American Inst. Mining Eng.

shipped; the finer portion being reserved until a suitable concentrating plant shall have been erected. This care in sorting the ore is rendered necessary by the presence of particles of jasper in the ore, which, if not removed, subject the ore to a penalty for silica.

The ore is stored on the upper level in a fifty-ton bin at the loading terminal of a Bleichert tramway. The tramway, about $\frac{1}{2}$ mile in length, has its upper terminal 420 feet above the railroad to which it conveys the ore. At the railroad there is a 300-ton ore bin, from which the railroad cars are loaded. The tramway is operated by gravity, the descending loaded buckets developing 6 H. P. All mine supplies, timber, etc., are brought up to the mine on the tramway, which has a capacity of twenty-five tons per hour.

Hand drilling was used until the present year, when, on account of the difficulty of obtaining laborers during the revolution in the country, an air compressor was installed, driven by a 35 H. P. gasoline engine, and power drills are now used.

Electro-Magnetic Ore Dressing.

Written for the MINING AND SCIENTIFIC PRESS by W. G. SWART, Metallurgical Engineer.

Not long since, in a semi-technical magazine article, the statement was made that static electricity had not yet been harnessed to any commercial use. If this be a correct statement it becomes my pleasure and privilege to not alone chronicle the first commercial use of static electricity, but also the fact that such use is in the field of ore dressing.

In February, 1901, letters patent were granted Lucien I. Blake, professor of electrical engineering of the State University of Kansas, and Lawrence N.

jack," but only such as is removable by separation of the crystals or particles.

So little has been done toward applying static electricity to commercial uses, and so little is known of its requirements in handling, that it has been no easy matter to work out a successful commercial machine. The problems of proper distribution of the electric charge over the several parts of the machine and successful insulation of high voltages in the face of dust, moisture and mill conditions generally, are but two of the many solved. A simple means of controlling the effect of violent fluctuations of the static charge has been found, its only disadvantage being a slight decrease in unit capacity of the machine. The voltage has gradually been reduced from 250,000 until now perfectly satisfactory work is being done at from 10,000 to 20,000 volts, representing a spark from $\frac{1}{4}$ to $\frac{1}{2}$ inch in length. A static generator has been devised by Prof. Blake and Mr. Morscher, constructed almost wholly of metal, using no glass whatever, self-exciting and able to run continuously in the open air without regard to atmospheric conditions, and with no more attention than an ordinary dynamo receives.

The separating machines, as at present constructed, have a nominal capacity of from twelve to fifteen tons per twenty-four hours, working on blende concentrates at 30-mesh. As in most other methods of ore dressing, the capacity is largely governed by the mesh, coarse material passing through rapidly, while fines go more slowly. The Blake-Morscher machine works well on some material at 6-mesh and will also handle material at 200 mesh with but slight change of construction or adjustment. As in other methods, sizing improves the products, but close sizing is not essential nor even desirable. On an 8-mesh jig concentrate a sizing at or near 20-mesh will usually give the best results, coarse and fine being handled separately on the same machine, which

rator without sizing or roasting, at the rate of 16.11 tons per twenty-four hours.

RESULTS.—Assays and weights of separated products:

Metal.	Original Material.	Iron Concentrates, 18 22% of total weight.....	Clean Zinc Blende, 80 21% of total weight.....
Zinc.....	49.20%	3.60%	60.69%
Iron.....	9.62%	39.24%	2.02%
Lead.....	2.28%	8.89%	Trace.
Silica.....	4.60%	5.00%	3.10%

REMARKS.—By "silica" is meant "insoluble residue."

A loss of 1.57% in weight is due to dust, samples taken during run, etc.

Any copper present is thrown with the iron and lead.

Sizing this material at 20-mesh, putting the fine and coarse over separately and combining the final products, gave better results, the clean zinc product carrying 61.81% zinc.

On the Colorado "black jack" ores I quote the following illustration:

ORE.—Leadville zinc and iron middlings.

(NOTE.—The Leadville crude ore is a solid mixture of sulphides of lead, zinc and iron, with practically no gangue. This is crushed to 30-mesh by rolls and concentrated wet on Wilfley tables which take out the greater portion of the lead, at the same time discarding a portion of such silica as may be present. The remaining "middlings" product, consisting of

Electro-Magnetic Ore Separator.

Electro-Magnetic Ore Separator.

Morscher, of Neodosha, Kansas, graduate student at the Kansas University, for a process of ore separation and apparatus based thereon. Briefly stated, the method consists in bringing a mass of ore particles into contact with a statically charged metallic surface. Such particles as possess relatively high conductivity are instantly repelled, while those of low conductivity are not repelled until sufficient time has elapsed to allow them to be pulled out of their original path and caught in a separate receptacle, thus effecting a separation from the conductors.

For a considerable period prior to the issuance of these patents a machine had been in successful operation in Denver, working on miscellaneous ores, and in many cases with notable results. This machine has since been simplified and compacted and the details improved until it is now doing steady and satisfactory mill work.

It is found by experiment that most of the sulphides and many of the other compounds of the valuable metals possess high conductivity, while the gangue consists largely of non-conducting material such as quartz, lime, etc. There are exceptions on both sides: The compounds of zinc, for example, are non-conductors, thus allowing a separation to be made between pyrite, galena and chalcopryrite on the one side, and zinc blende on the other, with no preliminary roasting, dryness being the only requisite. Magnetite and pyrrhotite may also be separated from blende. It is immaterial whether the blende be the "rosin jack" of the Joplin fields or the "black jack" of Colorado, the action being identical on both. Since this separation is mechanical and not chemical, the combined iron cannot be taken from "black

jack" double for the purpose. The standard machine is a double one 24 feet long, 41 inches wide and 81 inches high, using about 1 H. P. This latter covers generation of the static charge and is the total power consumed by the machine. The machine is constructed chiefly of wood, there being no complicated or expensive parts, and but few wearing parts. The cost of construction does not exceed \$900, including static generator, Denver prices.

As typical of the work of the machine I give the following results from my record, taking fair sized lots rather than hand samples. One peculiarity of the machine is that it has invariably done better work in quantity than was indicated by preliminary hand samples.

On the mixed sulphide concentrates of the Missouri-Kansas district, consisting of rosin zinc with a greater or less admixture of pyrite and galena, the machine does its best work, on ores so far tried. I select the following run from among many:

ORE.—Joplin jig concentrates, bought in the open market at Joplin.

WEIGHT.—482 pounds.

MESH TEST—

6 on 8 mesh.....	8.22%
8 on 12 mesh.....	6.85%
12 on 16 mesh.....	15.07%
16 on 20 mesh.....	12.93%
20 on 40 mesh.....	24.35%
40 and finer.....	32.57%

There is thus 43.97% coarser than 20-mesh and 56.92% finer.

TREATMENT.—Put over the Blake-Morscher sepa-

pyrite, pyrrhotite and "black jack," which in this case is a mixture of blende and marmatite, is dried and put over the electrical separators.)

WEIGHT.—2958 pounds.

MESH TEST—

30 on 60 mesh.....	33.8%
60 on 100 mesh.....	28.0%
100 and finer.....	38.2%

(NOTE.—17.8% passes 200 mesh.)

TREATMENT.—Put over the Blake-Morscher separator without roasting or sizing, at the rate of 12.83 tons in twenty-four hours.

RESULTS.—Assays and weights of separated material:

Metal.	Original Material.	Iron Concentrates, 47.80% of total weight.....	Zinc Blende Product, 50.88% of total weight.....
Zinc.....	30.37%	8.14%	51.18%
Iron.....	20.14%	35.14%	8.80%
Lead.....	4.60%	9.05%	10.60%
Silica.....	3.30%	4.60%	2.70%

REMARKS.—"Silica" is "insoluble residue."

A loss of 1.22% of total weight is accounted for in dust, samples taken during run, etc.

At the works of the Colorado Zinc Co. at Denver

one of these machines has been steadily doing this same class of work for some little time, and others are to be put in shortly there and elsewhere. The owners of the patent are careful, conservative men, preferring to go slowly with such an innovation, hence publicity has not been sought but rather avoided.

The machine is not confined in its operations to ores of zinc. All metallic substances, most sulphides and arsenides, and some carbonates and oxides are thrown out of a siliceous or limy gangue, in many instances the saving of values being very high. This is particularly true of the sulphides of copper.

The machine as ordinarily constructed makes no final middlings, the final separated products containing all the material originally charged. It can be arranged in the case of coarsely crushed ores to deliver a middlings product for re-crushing when necessary.

Considering the fact that here is a machine low in first cost and with a nominal operating expense, that it separates materials without regard to their specific gravity, that it works well at any mesh between 8 and 200, that no roasting of sulphides is necessary, that no water is required, that no piece of the machine weighs 100 pounds, that any intelligent mill man or mechanic can build one and keep it in repair, it is not too much to say that these results are remarkable and a valuable addition has been made to the science of metallurgy, for which due credit should be given to Prof. Blake and his associates.

The engravings accompanying this description are of the machine at the Colorado Zinc Works in Denver.

Denver, January 17.

Mines and Metallurgy at the St. Louis Exposition.

The exhibits of the Exposition will be presented in fifteen departments, which cover in their scope every phase of human endeavor and the earth's resources.

is being erected, and arrangements and appropriations for which department have been provided. The accompanying engravings illustrate the mining building from various points of view.

Precipitation of Copper Cyanide Solutions.

Written for the MINING AND SCIENTIFIC PRESS by
R. STUART BROWNE.

"It is one problem to dissolve the gold, and several problems to precipitate it."

I don't know who first recognized this fact and put it into the above concise statement, but whoever it was deserved an M. E., for he had learned cyaniding in a hard school, that of experience. It has been my luck to be continually running up against some problem in precipitation brought about by the presence of copper. A small amount of copper in the zinc box will frequently act beneficially in the precipitation of gold and silver by the formation of a couple. But I have observed that this excellent servant very soon becomes a very bad master. I prefer to dispense with his services, for after he has once gained a foothold on the zinc his removal is always attended with considerable trouble. Unlike gold and silver, which form a spongy precipitate on the zinc, the copper deposits a hard film, which prevents further contact between the zinc and the solution. Zinc in this condition is not necessarily rendered useless. Copper is soluble in strong cyanide solutions, so that by raising the strength of the solution flowing through the box the copper can be removed. Just what the proper strength should be is a matter that must be determined by experiment. In working ores containing copper I use very weak solutions, which on leaving the leaching vats seldom carry over 1.5 pound of free cyanide per ton. By raising this to 10 pounds

use a strong solution in leaching ores containing copper, for the selective action of cyanide for copper increases with its strength. There is a chemical law governing the amount of cyanide necessary to keep the copper in solution. If the amount of cyanide remains constant and the copper accumulates, a point will be reached when the copper will precipitate on the surface of any exposed zinc. In dealing with the problem of precipitating from copper solutions I keep one rule in mind: "Don't use any more zinc in the boxes than is necessary, the amount to be governed by the quantity that can be kept coated with gold and silver." There is no use in filling up a dozen compartments with zinc when the first three or four precipitate the gold and silver and the others copper. It is much easier to keep a small amount of zinc in working condition than a large amount. Working along on this line I get a successful precipitation from the most unfavorable kind of solutions. As the copper accumulates in the solution it becomes impossible to add fresh zinc to the boxes without an immediate precipitation of the copper. Raising the strength of the solution does not help the matter, for the copper acts quicker than the cyanide. It becomes necessary to give the zinc a protective coating before placing it in the zinc boxes. In the Betty process the shavings are dipped in a solution of lead acetate. This gives a coating of spongy lead, which not only protects the zinc from the copper, but assists the precipitation of the gold and silver by the formation of a couple. The usual method of procedure is to make up a 10% solution of lead salt, dip the shavings into it, then pack the boxes and run strong solution through for twenty-four hours, gradually reducing the strength to the normal figure. I can see no reason for making the lead solution up to any definite strength. Any will do, provided it contains sufficient lead to cover the zinc. Before dipping, the zinc should be pulled apart to make it fluffy. All of the little hard balls formed during the cutting should be removed. It is in these balls that the copper and other base metals find a foothold, from which it is almost impossible to remove them.

The thickness of the shavings is a very important matter. I have found that the thinnest of machine-cut shavings give the best results. It is easier to keep them free from copper than the coarser kind. To get a box ready for precipitating, I first clean it out thoroughly, then pack my dipped shavings in loosely, but pressing them down more firmly along the sides. As soon as one compartment is filled I run in fresh water to prevent oxidation. This oxidation of the zinc I have not seen spoken of before. It is a very important matter, for it is the cause of a great deal of poor precipitation. In a cleanup it is customary to wash the shavings and then to put them to one side, to be replaced later. If the zinc is not covered with either water or solution it commences to heat. The rise in temperature is due to the formation of a film of oxide on the zinc. After this the shavings are almost useless for precipitation. After being once wet they should never be allowed to dry again. When all of the compartments are packed I run clean water through them until the cloudiness due to the formation of basic lead salts has passed away. Giving the zinc a water wash is unusual, but I have found it beneficial. I then add solid cyanide to each compartment and turn in a rich solution, which is brought up to about 3 pounds strength. The next

Mines and Mining Building, St. Louis Exposition, 1904.

The achievements, history and possibilities in mining and metallurgy are to receive special attention and extensive treatment and display at the Exposition of St. Louis, 1904. The authorities of the Exposition

strength (0.5%) I can usually clean the copper out of a box in forty-eight hours. It is useless, however, to attempt to remove the copper unless it can be replaced with either gold or silver or some other metal,

Portal Mining Building, St. Louis Exposition, 1904.

Mines and Mining Building, St. Louis Exposition, 1904.

have given the various materials, industries and pursuits which are included or implied under the heading, "Mines and Metallurgy," such as working of mines, ore beds and stone quarries; minerals and stones and their utilization; mine models, maps, photographs; metallurgy, literature of mining, metallurgy, etc., a leading place in the classification of the Exposition. These have been embraced in one of its principal departments, a special building for which

for on reducing the strength of the solution the copper will immediately reprecipitate. For this reason a rich solution should be run through while the zinc is being cleaned. Once the zinc has been given a protective coating there is very little further danger from the copper, and the strength of the solution may be reduced. It would seem that if strong solutions were always used there would be very little trouble from the copper. But it is not advisable to

day the solution is allowed to fall to its ordinary strength. When it becomes necessary to add fresh zinc I first dip the shavings and then wash them thoroughly in a tub with a slow-running stream of water. At the present time I am precipitating from a solution carrying about 4.5 pounds of copper per ton, \$4 in gold and 1.5 ounce of silver. The precipitating boxes contain three compartments, each 18 inches square in the clear. The rate of flow is 1 ton

per hour through each. After leaving the boxes the solutions seldom assay over 20 cents. The precipitation of the silver is always complete. The tailings resulting from pan amalgamation always contain considerable copper and floured quicksilver. The quicksilver, which readily dissolves in the cyanide and precipitates in the boxes, exerts such a beneficial influence on the precipitation of the gold and silver that the presence of the copper occasions no trouble. While connected with the Nevada Reduction Works at Dayton, Nev., a couple of years ago, I had an excellent opportunity of observing the action of quicksilver. In addition to cyaniding the ore coming from their own mill, the company was treating a considerable quantity of tailings from one of the old Comstock pan mills. The quicksilver was completely precipitated in the first three compartments. The shavings would turn white and become very brittle. The precipitation of the gold and silver might be called perfect. An assay of 300 cubic centimeters of solution that had passed through the boxes would not give a weighable bead. At the same time all of the zinc in the lower compartments was completely coated with copper, while not a trace was to be seen in the upper ones. Below the fourth compartment the precipitation of the values was practically nil. The solution running through the boxes usually contained less than 1 pound of free cyanide per ton. An interesting fact was the recovery of a considerable quantity of amalgam from the boxes during the monthly cleanup. After refining the precipitate in the usual way—with sulphuric acid—the quicksilver was recovered by retorting. The amount thus recovered was considerable. The most rapid and convenient way of determining the amount of copper in a cyanide solution that I have found is a modification of the method devised by A. H. Low for determining the copper in an ore. I take from 50 to 100 cubic centimeters of the cyanide solution and add H_2SO_4 until it is strongly acid. The acid will throw down a portion of the copper as cuprous cyanide. This precipitate is white and curdy, somewhat resembling silver chloride. The solution is now brought to boiling over a laboratory lamp to drive off the free hydrocyanic acid. After a few minutes nitric acid is added, a drop at a time, until the cuprous cyanide is completely dissolved. About 5 grams of sheet zinc is then added to throw down the copper. The excess of zinc is then dissolved by a fresh addition of H_2SO_4 and the residue washed by decantation. The copper is then redissolved in nitric acid, NH_4OH added, and the copper determined by titrating with standard KCy.

of normally insoluble salts soluble in water, then washing away the soluble portion with water, treating remainder with hot alkaline solution, again washing with water.

PROCESS OF SEPARATING PRECIOUS METALS FROM THEIR ORES.—No. 718,087; F. R. Carpenter, Deadwood, S. D.

The process of treating dry ores for separation of gold and silver which consists in smelting ores with sufficient basic material to form slag, and insufficient fuel to effect any material reduction of contained metals, and bringing resulting molten mass into contact with molten metallic bath capable of absorbing precious metals from matte.

WELL DRILLING MACHINE.—No. 718,112; H. H. Everhard, Massillon, Ohio.

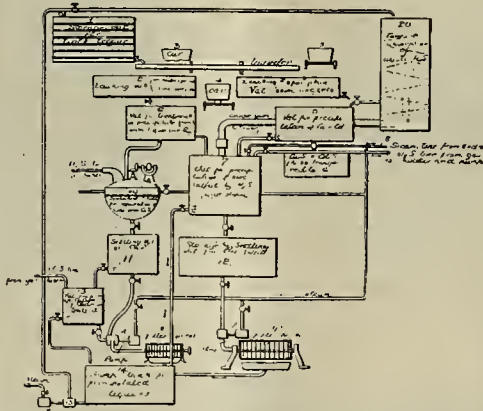

In well drilling machine, suitable frame, power shaft provided with a crank, shaft provided with toothed segment, worm gear meshing with toothed segment, means for rotating worm gear, links connected to shaft provided with toothed segment, swinging arms carrying an axle and drill operating wheel, and swinging arms and links fixed to toothed segment shaft hinged together, and pitman connected to crank of power shaft and to axle of rope operating wheel.

MINER'S LAMP.—No. 718,128; J. Jacobsen, Lethbridge, Canada.

In miner's lamp, combination with plate or bracket having upper rearwardly curved top securable to cap and forwardly curved bottom end securable upon vizor of cap, and intermediate forwardly projecting cheek plates having downwardly and forwardly slanting notches, of lamp having side trunnions adapted to rest in notches; and friction held hooks 14 closing notches to prevent accidental displacement of trunnions; and combined hook and handle 18, fixed to rear of upper part of lamp and projecting above same, and clearing for hook in bracket.

METHOD OF EXTRACTING ZINC.—No. 718,554; W. G. Waring, Tyrone, Pa.

The process of leaching crude zinciferous ores, residues or products by leaching agent consisting of dilute acidulated water containing not more than 1.5% free sulphuric acid, together with indefinite amount of dissolved ferric sulphate; precipitating metals of copper group by agitation with slight ex-

cess of soluble sulphide, and finally separating zinc by means of hydrogen sulphide.

METHOD OF MAKING PURE HYDROGEN SULPHIDE FROM FURNACE GASES.—No. 718,556; W. G. Waring, Tyrone, Pa.

Method of converting sulphur dioxide contained in furnace gases or in other admixture into pure hydrogen sulphide, which consists in absorbing sulphur dioxide in strong solution of sodium sulphite, combining sulphur dioxide so absorbed with barium, by means of reacting upon barium carbonate with acid sodium sulphite so produced; storing evolved pure carbon dioxide; reducing barium sulphite thus produced to barium sulphide by means of calcination with coal, finally causing carbon dioxide stored to react upon barium sulphide, so as to produce hydrogen sulphide, with regeneration of barium carbonate.

PROCESS OF RECOVERING PRECIOUS METALS FROM MATTES CONTAINING THEM.—No. 718,089; F. R. Carpenter, Denver, Colo.

The process of separating precious metals from matte containing them, which consists in causing intimate mixture of matte with metallic iron and subjecting mixture to bath of molten metallic lead.

PROCESS OF SEPARATING PRECIOUS METALS FROM ORES.—No. 718,088; F. R. Carpenter, Denver, Colo.

Process of separating precious metal from iron matte containing it, which consists in bringing molten iron matte containing precious metal and molten metallic lead in contact with each other and subjecting former to oxidizing atmosphere.

BLAST FURNACE.—No. 718,313; W. C. Coffin, Pittsburgh, Pa.

In blast furnace combination of hearth having outer wall consisting of horizontal bands or rings formed of channel bars, cooling plate holding devices interposed between adjacent bands or rings, hosh having outer wall sustained by outer wall of hearth, hosh outer wall being formed of plurality of hands or rings formed of Z-bars, and cooling plate holding devices interposed between adjacent Z-bar rings, thereby forming a continuous metallic outer wall for hearth and hosh.

THE ore from Gold Hill, Or., is marcasite, a light-colored iron sulphide. It may be gold bearing. The small flat crystals in the cavities are characteristic of the mineral. Its hardness and streak are also characteristic.

Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 13, 1903.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MINE GATE.—No. 718,138; J. M. Marty, Cleveland, Ohio.

In mine gate, combination with track rail, of secondary rails on each side of gate, weighted levers attached to secondary rails, curtain mounted in frame and operated by a pair of lazy tongs, and rods for connecting secondary rails and weighted lever to lazy tongs, whereby curtain is raised as car approaches gate and lowered as car leaves gate.

METHOD OF REDUCING ORES.—No. 718,099; S. C. Currie, New York, N. Y.

Method of treating pulverized ores containing precious metals and other substances, which consists in treating ore with a heated gaseous compound containing oxygen, at temperatures which render some

Mining Summary.

Specially compiled and reported for the
MINING AND SCIENTIFIC PRESS.

ALASKA.

The Alaska Dispatch says the Sumdum Co., near Juneau, have struck their ore body, finished their up raise, and the stamps are dropping. The ore body cut in the Old Chief shaft runs \$16.

A strike is reported at Tanana district, on the American side. Japanese arriving in Dawson from the diggings verify the statements. Many are leaving Dawson. The weather is very cold and travel is heavy over the new mountain trail to White Horse.

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—The property of the Dragoon C. M. & S. Co., at Pearce, is being developed. The gallow-frame at the new shaft has been finished and a 34 H. P. gasoline hoist is installed. Work has been resumed in the shaft. The shaft is down 80 feet and the indications are good at that depth. A millsite with plenty of water has been secured, and the building of a smelter is being considered. Four miles of wagon road have been made the past two months, and a steel track, 700 feet in length, is being laid from the foot of the mountain, to facilitate raising of materials to the mine by means of cars and cable. The Dragoon claims, twenty in number, are in the Dragoon mountains, west of and adjoining the property of the Black Diamond C. Co. The latter company is completing a 200-ton smelter, which will be blown in about Feb. 1. A tramway 1½ mile in length is in operation.

Pearce, Jan. 13.

The Copper Crown Co. reports cutting a body of sulphide ore on its property in development work. The group consists of fourteen claims near the Black Diamond mines in the Dragoon range, near Tombstone.

At the Tombstone Con. M. Co.'s shaft they are 75 feet below the 600-foot level.

G. Moran, superintendent of the Golden Era mine in Easter Sunday district, near Bisbee, says one of their shafts is down 125 feet and sinking.

Manager J. S. Palmerlee, the Huachuca Con. M. Co., in the Huachuca mountains, near Bisbee, says the crosscut being driven for the Gertrude ledge is in 70 feet and is expected to cut the vein at 125 feet.

COCONINO COUNTY.

The smelter of the Anita Con. C. Co. at Williams is in operation. H. I. Nesmith is manager.

GILA COUNTY.

H. J. Sisty, developing the Sultan group of claims in Lost gulch under a lease and bond, says that in the Badger claim the drift at 120 feet depth is being extended, and for the last 30 feet has been on a 2-foot vein carrying gold and lead.—On the Cedar Tree work was resumed at the point where the vein appeared to have faulted, and, after crosscutting a few feet, the lead was recovered. The ore in the Cedar Tree is similar to that in the Badger, averaging \$45.—On the Montana shaft has been sunk to 40 feet and is in ore that will average \$6 gold.

Manager V. V. Clark is building a 10-stamp concentrating plant and a 500-foot tramway from the shaft to the mill at the Yo Tamblen, near Globe, with thirteen men. C. Crowley has struck a sulphide ore in the tunnel on the Hal and Al. He has developed a body of carbonates in the 45-foot winze in the tunnel, but had to stop on account of water. At the Great Republic group, adjoining the McNally claims, the main tunnel, 250 feet, in sulphide copper ore, has caved and is being cleared and timbered.

MARICOPA COUNTY.

The Maricopa mine near Cave Creek is reported sold to Galpin & Son, N. Goff, W. K. James, C. Davies and S. F. Fitchett, of Prescott, for \$18,000. The Maricopa is near the Phoenix mine.

MOHAVE COUNTY.

The Chloride G. M. Co., operating the Samoon and the Fourth of March mines in the Wallapai district, 3 miles east of Chloride, are shipping \$100 ore to the smelter. L. Hoffman is manager.

J. Barry has let a contract for 100 feet of tunnel on the Gold Nugget mine at Cerbat, near Stockton Hill, 14 miles north of Kingman.

PIMA COUNTY.

(Special Correspondence).—The Loma Verde C. Co. is developing fourteen claims 15 miles east of Tucson. A shaft is down

350 feet and a crosscut at the 100 level is in 100 feet. Stations have been cut at the 200 and 300 levels. The ore contains copper and gold, averaging \$50 to \$75 per ton. Tucson, Jan. 19.

Baxter, Irish & Ellis, working the Twin Butte mines, 27 miles south of Tucson, have a shaft on the Glance 185 feet and have crosscut 45 feet in ore. They have a shaft 125 feet deep on the King claim. There are nineteen claims in the group.

PINAL COUNTY.

In Quezon Creek district, 4 miles from Silver King, the Sieboth Co. has forty men at work on the Lobb mines, with one tunnel in 325 feet and the second 240 feet.

SANTA CRUZ COUNTY.

The Nogales Co. will install two 100-ton reduction plants—one to be at the Buena Blanca mines, near Nogales.

YAVAPAI COUNTY.

(Special Correspondence).—The Clune M. Co., in the Mineral Paint district, have four men driving the tunnel of the Maud mine. The ore runs \$30 to the ton. Prescott, Jan. 20.

During the shut down at the United Verde mine at Jerome, the 250 ton water-jacket furnaces at the smelter were replaced with 500-ton furnaces.

The Red Apache mine, near Lynx creek, owned by W. Lacase, is showing an ore body 3 feet wide, carrying gold values. The tunnel is in 135 feet.

North of the Lynx creek dam a strike is reported in the North Star mine by S. W. Gleason & Co. The ore body is 4 feet wide and runs \$10 in gold.

Work has begun on the Gold Nugget and Union mines, east of the Lynx creek crossing on the McCabo road.

The White Horse Co. is opening up a prospect 1 mile south of their hoist and have cut a body of ore running \$50 in gold.

H. B. Clifford has bought the Peck property, 36 miles from Prescott in the Bradshaw mountains, and will put in machinery to unwater the mine.

The Iron Queen mine, owned by the Treadwell Co., is down 315 feet. They have thirty-five men at work and intend to sink to the 500-foot level. The ore carries copper and gold values.—The Treadwell Co. has a hoist on the Hackberry mine and five men at work hoisting water, with 150 feet of water yet to raise.—The French Lily mine, on Turkey creek, is down 190 feet.

Two cars of ore from the Gladstone dump, at Big Bug, were shipped last week.—It is reported the Jesse mine, in Chaparral district, will resume.

CALIFORNIA.

AMADOR COUNTY.

(Special Correspondence).—P. Eichelroth, superintendent of the Sand Pile mill, owned by Fricot & Miller, has returned from San Francisco and the southern counties of the State investigating cyanide plants. The Confidence plant, 15 miles east of Sonora, in Tuolumne county, he considers best adapted to his purpose. Mr. Eichelroth will erect a cyanide plant of 300 tons capacity, near Forest Home, for the treatment of tailings from the Plymouth Con. mines at Plymouth. Plymouth, Jan. 19.

CALAVERAS COUNTY.

(Special Correspondence).—W. E. C. Eustes, president of the Melones M. Co. of Boston, Mass., who arrived here a couple of weeks ago with W. B. Devereux, managing director of the company, has returned to Boston. Mr. Devereux will go to New York in a few days. The offices of manager and superintendent have been consolidated, F. Langford having been appointed to the position on Jan. 13. Development work is progressing and sixty stamps are dropping. Mr. Devereux is making tests and experimenting on treatment of the ore, to lessen the cost of handling. At present the ore is being hauled from the tunnel 4000 feet to the mill by four cars, of eight tons capacity each, drawn by electric locomotive. Melones, Jan. 20.

(Special Correspondence).—The '49 Gold Placer M. Co., under direction of J. M. Evans, superintendent, are erecting a gallow-frame and placing the hoist formerly at the Lightner mine on their property at Douglas Flat. The hoist will be run by steam with water power auxiliary, and will be working Feb. 15, when the shaft will have reached the 200 level, where it is expected bedrock will be struck. Two 14-inch pumps are also being put in.

T. H. Fullen, superintendent of the Angels Quartz M. Co. at Angels, says the 20-stamp mill crushes 100 tons daily.

At the Lightner mine at Angels, under management of A. Chalmers, a new change room, containing shower baths, has been put in. Each man is given a

wash sult and locker, which he is required to keep in order. An emergency room has been added for use in case of accidents, supplied with such articles as are required for first aid. A new hoist has been put in costing \$5300, the old hoist being too light for the required work. Fuel oil is used and large tanks have been erected. Oil is also used in the chlorinating plant; a saving of 40% on fuel cost is reported. The company has bought a portion of the Lindsay lot, south of the mill, giving room for additional stamps to be added to the forty as soon as the lower levels have been opened. Sixty-three thousand tons of ore were crushed by forty stamps in 1902. The reported profit for 1902 was \$119,065.90, of which \$51,127.50 was paid as dividends and \$36,428.86 as balance of amount due on the purchase of the mine. Angels, Jan. 19.

(Special Correspondence).—The Union C. M. Co., operated by the F. L. Ames estate of Boston, Mass., under superintendency of David Ross, are working twenty men on repairs and preparing to resume operations.

Copperopolis, Jan. 19.

At the Independence mine, near Angels, they are putting in a 65 H. P. boiler and a 10-inch pump. The shaft is down 50 feet.

A 40-foot water wheel has been put in the Claxton mine to unwater the mine.

The Beatrice mine, near Murphys, has been closed down.

DEL NORTE COUNTY.

At Camp Crawford in Diamond Creek district eight men are at work in the Crawford copper mines. A tunnel is being driven to tap the ledge on the 500 level and is in 295 feet.

EL DORADO COUNTY.

The mill at the Esperanza mine, near Garden Valley, has been sold to the Gold Tunnel M. Co. and will be taken to Placer county.

A 10-stamp mill is to be put up on the Crystal mine, near Omo.

FRESNO COUNTY.

The Esperanza, in the Coalinga district, has completed another well.

INYO COUNTY.

(Special Correspondence).—The Arroyo G. M. Co. of Los Angeles have a 100-ton plant in operation in the Argus mountains. A tramway will be built. A large vein is reported. It is expected that the cost for chemicals and treatment of the ore after crushing will be very low. They expect to mine and mill the ore for \$1 per ton. The ore averages \$4.60 per ton.

The Cecil R. G. M. & M. Co., owning mines in South Park district near Ballarat, are installing a 10-stamp mill and cyanide plant, to be in operation by the 15th of February. Development work is pushed with twenty men. An addition to the mill is anticipated. There is 600 feet of development work done. Ballarat, January 19.

The Roosevelt Oil Co., operating near Hawaii, has 13,000 feet of lumber at Keeler to be used in building eleven oil derricks. The well is down 1100 feet.

KERN COUNTY.

J. E. Beard and W. W. Stevenson are drilling near the Spellacy wells at Midway. The Paraffine Oil Co. has resumed drilling at Tembler.

A corporation, to be known as the California Con. Oil Fields Co., is to be formed by H. A. Blodgett and S. Jewett of Bakersfield, who own large interests in the Sunset field, and foreign capital, to handle the product of the Sunset and Midway districts. The corporation takes in all producing properties in these two districts. They will erect five tanks of 35,000 barrels capacity each, and add to them when necessary. The capacity of the refinery at Sunset will be enlarged. A pipe line 10 miles in length, exclusive of laterals, will be constructed to connect the Sunset and Midway districts with the terminus of the Sunset Railway, where the tanks will be located. The line will be constructed of 8-inch and 10-inch pipe, and the laterals of 4-inch and 6-inch pipe.

MADERA COUNTY.

(Special Correspondence).—The Jessie Belle M. & S. Co. will build a smelter on their property near Daulton. Two carloads recently shipped are reported to average 22% copper, about \$12 gold and \$5 silver. Sixty-six feet of work has been done on the Copper Queen mine, belonging to this company, and 118 feet on the Daulton mine.—T. S. Orr of Denver, Colo., recently bought the old Buchanan mine in that vicinity and has it in operation.

Daulton, Jan. 21.

MARIPOSA COUNTY.

J. Helm and C. Czerny are reported to have taken out a pocket last week that

yielded \$1450, at the Tramp mine, at Whitlock, which they have on a bond.—Last week W. Dolph took out \$500 and ten tons of milling ore that assays \$50 per ton from the Hayseed mine.

NEVADA COUNTY.

The South Idaho M. Co. has secured an extension of bond for one year on the South Idaho, near Grass Valley.

The hoisting works of the East Orleans mine, near Nevada City, recently bought by the Gold Tunnel M. Co., were destroyed by fire on the 18th inst.

The Gold Tunnel M. Co. has a bond on the Gracie mine on Gold Flat, near Nevada City.

ORANGE COUNTY.

(Special Correspondence).—The Santa Ana Tin M. Co. is working ten men in Trabuco canyon on development; power drills are to be put in. The company own 7000 acres. Gold ore discovered will average \$5. Gall Borden of Alhambra is president.

Santa Ana, Jan. 21.

PLACER COUNTY.

At a recent meeting of the citizens of Forest Hill to prevent wholesale grabbing of timber land in the mineral belt in eastern Placer, a committee was appointed to raise funds to file a protest with the registrar of the land office.

Manager J. Manson has put in a 20 H. P. electric motor at the Calf Pasture mine, near Auburn, and the mine is being unwatered.

SACRAMENTO COUNTY.

The tunnel at Twin Brothers M. Co. quartz mine, near Folsom, is in 250 feet.

SAN BERNARDINO COUNTY.

(Special Correspondence).—The Giant Ledge G. & C. Co. are working on the north end of their mine near Manvel in the New York mountains. The Hard Cash is the principal one. The vein is 50 feet wide.

R. Young has a body of ore 6 miles west of Manvel. A crosscut in 70 feet has not found the wall.

The New York mines, known as the Alpha group, has 3000 feet of development which is being cleared out by Doak & Co., and a concentrating plant will be put in.

Thompson, Wheeler & Co. have bought the Boomerang mine and other property, owned by the Campbell estate at Vanderbilt, and have begun operations.

The Oro Rico Mining Syndicate is working in the south end of Providence mountains. A body of ore has been cut in the Confidence mine, which assays \$100 per ton. A mill and concentrator is to be put in. There are thirty mines in the three groups owned by this company. The Oro Rico Syndicate was formerly the Providence Gold Syndicate.

Manvel, January 20.

(Special Correspondence).—The Dean & Jones M. Co., Slate Range, are working sixteen men on development and cyaniding tailings, which have encroached upon the mill.

Randsburg, January 20.

Drillers working for the Riverside Water Co., a mile west of San Bernardino, struck a flow of boiling hot water at a depth of 350 feet. The water is heavily charged with sulphur.

A. P. Thompson & C. Colton at the Hunter-Paymaster mines on Old Woman's mountain, near Danby, have a tunnel in 360 feet and a shaft down 90 feet and a main tunnel on which they are working in 260 feet. This tunnel has another 100 feet to run to tap the ledge at a depth of 500 feet. In the Paymaster they have a tunnel in 50 feet and will run 50 more.

The Silver Wave mine of the Danby M. & M. Co. on Old Woman's mountain has shut down temporarily and its 10-stamp mill at Danby is idle. S. & W. Heath have six men doing development work on the Manoa.

SAN DIEGO COUNTY.

(Special Correspondence).—Banner is to have a smelter. Lumber and fuel are now being hauled to the site.

Banner, Jan. 19.

SHASTA COUNTY.

Twenty deputy sheriffs, armed with rifles and shotguns, guarded the entrance to the property of the Mountain Copper Co. on the 19th inst. It was the first attempt of the company to set men at work since the strike begun Nov. 21. With the deputy sheriffs stood fifty of the leading citizens of the town of Keswick, all of whom had last week signed resolutions commending the course of the company and condemning the position and demands made by the union. There were present 105 strikers, but no demonstration was made.

W. Dunham reports a 3-foot ledge of sulphide ore at 40 feet in the Mocking

Bird's lower tunnel on Mule mountain, 4 miles northeast of Igo.

The Original Quartz Hill G. M. Co., near Redding (known as the Polish Co.), will resume. Their property is the Kosciusko Con. mine and the Isaacs placer on Quartz hill.

A. C. Brokaw is putting an air compressor in at his quartz mill at Hull gulch, in Quartz valley, to run pumps, mill and drills.

W. G. Scott & H. Tarbot have located the Montelado and Riolado, east of the Afterthought copper mine, near Bella Vista. They claim they have a vein carrying 12% lead with silver.

Copper ore is reported at the Modoc Chief quicksilver mine of the Modoc Chief Co. on Clover creek, near Millville.

W. W. Adams, superintendent of the Balaklala copper mines of the Western Exploration Co., says operations are resumed.

SIERRA COUNTY.

At the Oriental mine, a mile from Alleghany, Superintendent H. L. Johnson has the lower tunnel in 1845 feet and driving at the rate of 6 feet a day. Three shifts and two machines employed. They expect to strike the ledge this week. The tunnel is 800 feet lower than the bottom of the shaft, which was sunk 600 feet on the ledge. Fifteen men are at work.

J. Bothwell has a contract from I. Copeland to run a tunnel to tap the Buckingham ledge on Jim Crow ridge, near Downieville.

SISKIYOU COUNTY.

The McKinley mine on Sucker creek, Humboldt district, near Fort Jones, owned by Koontz, De Witt & Martin, has been bonded and development work begun.

Machine drills are in operation on the main lower tunnel of the Cherry Hill mine, near Fort Jones.

(Special Correspondence).—The Yreka M. & M. Co.'s mill is in constant operation. The 20-stamp mill was started December 20. The ore from the upper claims is carried to the mill by a bucket tramway. The December mill run averaged \$7 per ton. The company anticipates a good season. The water supply is exceptionally good this year.

The Jumbo mine, White gulch, has closed down. L. A. Carter & Sons' crushing netted over \$40 per ton. They project a mill next summer.

Rollin, Jan. 19.

The Punch Creek mine in the Humbug district, 7 miles west of Yreka, has been sold to G. W. Grayson of Oakland, Cal., for \$30,000.

Superintendent E. A. Scott of the Con. M. & D. Co.'s plant, near Callahan, says "during the past few months' experimental work we found it impossible for the dredger to get all the gold on the bed-rock owing to its being hard and rough where the heavy gold lodges. In order to remedy this the dredger was set stationary and a pit dug to bedrock by hydraulic lifting and use of dredger. Afterward a hydraulic pump was set in the pit which handles the water and the giant drives the gravel into buckets of dredger which elevate it 50 feet to the dumps."

The Siskiyou Electric Power Co., at Fall Creek, on Klamath river, has finished the ditch, 4800 feet in length, which will carry the water of Fall creek to a point above the power house, where a fall of 700 feet is available to develop electricity for supplying light and power in southern Oregon and northern California. The power house is to be of stone and will contain four Pelton wheels of 1000 H. P. capacity each. J. Churchill is president and A. J. Roshorough secretary. The towns included in the lighting circuit are Jacksonville, Medford and Ashland, in Oregon, and Hornbrook, Klamathton, Lairs, Ager, Montague, Yreka, Fort Jones and Etna, in California; power will be furnished to twelve mines, two box factories, three grist mills, one paper mill, two pumping plants and two railroads. The head office of the company will be at Yreka. E. H. Stul has charge of the installation and is manager for the company.

TRINITY COUNTY.

Superintendent Bouery of the La Grange mine, near Weaverville, says he has twenty-five men at work and three giants in operation using 3200 inches of water.

The Miner's Dream group, near Weaverville, is sold to M. W. Musgrove of Spokane, Wash. The group consists of the Miner's Dream, Ray of Hope and Gold Standard claims, a water right of 3000 inches on Brown's creek and a tunnel site.

E. F. Burrill of Berkeley has an option to purchase for \$30,000 the Senger and Hughes placers, near Blue gulch, in Weaver basin.

Hall & Duvergy of the Globe mine, near Dedrick, are building a flume to take water from Bear creek which will give 680 feet pressure to run the compressor at the

tunnel to be driven from the Bear creek side. This tunnel will be 3000 feet long and tap the Globe ledge at a depth of 700 feet.

TUOLUMNE COUNTY.

(Special Correspondence).—Development on the Bell mine begun six months ago is progressing. The shaft is down 450 feet and sinking will be continued. W. J. Rule is superintendent.

Tuttle-town, Jan. 19.

The Norwegian Co., near Tuttle-town, has been reorganized by Boston men as the Norwegian Con. M. Co. C. F. Benedict, W. C. Henry, J. E. Crumb are the officers, with C. E. Whiteford, superintendent; W. A. Pierce, foreman. The mine has been unwatered and ore is being hoisted from the first and second levels. It is intended to enlarge the mill and sink the shaft deeper.

The tunnel of the Mayflower Co., near Groveland, is in 420 feet. An upraise will be driven to the gravel.

At the Cosmopolite, near Groveland, the crosscut is in 225 feet. This mine has been a large producer in the past.

The Magnet reports work suspended at the Neubeaumer mine, near Tuttle-town. On the 400 level in the Bell mine they have an ore body 15 feet wide and 185 feet long.

At the Soulshy mine, Soulshyville, the shaft is being sunk to the 300 level and drifting north for the new shoot is being pushed. A winze was sunk on this shoot at the 200-foot level, giving assays of \$100.

Work has begun on the drift to connect the Jumper and Golden Rule mines at Stent.

At the Black Oak, near Soulshyville, forty stamps are dropping. The shaft will be sunk to the 1400 level.

The Seminole G. M. Co. has bonded to C. H. Thomas of Carters the Seminole mine, near Carters, with the millsite and mill and machinery thereon for \$35,000.

J. Rocca has bonded to D. Cinelli, H. A. Ross and C. Simi, for \$5000, the Lenormande mine on the Rocca ranch at Algerine.

COLORADO.

BOULDER COUNTY.

The Wall Street gold extraction mill is in operation.

CHAFFEE COUNTY.

The Futurity M. & M. Co. at Newett have the main shaft down 260 feet and in ore carrying "peacock copper" (bornite).

An onyx quarry has been opened below Wellsville and a carload shipped.

The Salida E. & D. Co. have opened the Pay Car near Salida and will develop by tunnel.

The Sedalia G. & C. M. Co. has incorporated; F. Shine, J. Hamilton of Leadville and E. B. Green of Denver. They have a ten-year lease on the Sedalia copper mine 4 miles from Salida and will put up a mill.

CLEAR CREEK COUNTY.

The Wilcox tunnel of the Waldorf mines, near Georgetown, is in 1040 feet, and is going ahead with power drills at the rate of 6½ feet a day. The heading is in hotite gneiss.

Work will begin Feb. 1 on the second and third adits of the Johnson vein, near Georgetown, both of which show ore in the headings. The Owsley workings are being driven under contract. The heading shows an 18-inch vein of galena and zinc blende.

At the Little Mattie M. & M. Co., up Chicago creek, near Idaho Springs, in the fourth level a 2-foot streak of smelting ore, assaying six ounces gold, has been opened by Lessee Parker.

P. R. Stanhope of Denver will develop the Silent Friend mine near Dumont. The Sun and Moon mine is using electricity. The Newhouse tunnel having drained the shaft operations are resumed.

A shoot of sulphuret ore has been cut in the lower tunnel of the Buckeye, near Georgetown. The upraise in the sixth level of the Centennial is being driven in a body of smelting ore which runs \$40. The Prudential Co. has let a contract for 200 feet to Valentine & Co.

A contract has been let for driving a tunnel for development of the Indiana G. & S. M. & M. Co.'s group of claims on the north slope of McClellan mountain, near Silver Plume.

The Pioneer mine near Dumont has been pumped out and contracts let in the drifts and shaft. The shaft is down 200 feet below the tunnel level. Gasoline runs the hoisting engine and the mine is lighted by electricity. The same company works the Milton mine and the Pioneer mill. The Monarch tunnel being run to the Freeland mine, which it will cut at a depth of 2200 feet, will resume. It is in 2000 feet.

At the Gold Dirt, near Empire, connection with the upper levels is being made by an upraise from the sixth or tunnel level. The Surprise group on Clinton

and Silver mountains, recently sold to Nebraska men, is shipping smelting ore from an 8-inch shoot in the crosscut, giving values in gold and copper.

Lessee Parker, on the fourth level of the Little Mattie mine on Chicago creek, near Lamartine, reports a 2-foot shoot of smelting grade ore opened up. One shipment made gave returns of 8 ounces gold per ton.

Haggart & Riley have a lease on the Edgar lode on Democrat mountain, near Georgetown. Smith & Co., operating on the Konigshurg on Democrat mountain, are shipping ore.

CONEJOS COUNTY.

The Conejos County Oil Co. has bought 2000 acres of ground near La Jara and will drill for oil. W. D. Mielr of Denver is president.

CUSTER COUNTY.

At the P. & O. mine, near Silver Cliff, the shaft has been retimbered and enlarged to the 500-foot level. Drifts are being run on the vein from this level by two shifts. Assays show \$10 in gold. The owners of the Spring Hill mine expect to sink the shaft to the 800-foot level. It is down 100 feet.

The tunnel on the Powhattan, near Rosita, is down 910 feet.

EL PASO COUNTY.

(Special Correspondence).—The Telluride R. Co. began operating its 100-ton plant in June, 1902, and finds the use of bromine to be in every way satisfactory. The company is adding 200 tons to its plant, which will be in operation about May 1. This will make a total capacity of 300 tons per day.

Colorado Springs, Jan. 18.

From the coal mines north of Colorado Springs shipments are being made to Kansas, Nebraska and Iowa points. The Pike's Peak Co. is sending 300 tons daily and will increase to 500 tons. The Curtis Co. is also shipping.

FREMONT COUNTY.

The A., T. & S. Fe R. R. Co. have thirty men at work opening up a sandstone quarry for holding stone 1 mile east of the Portland cement works, near Florence.

The Rita Alto mine, near Hillside, is being developed by two tunnels, one 700 feet and the other 415 feet, each of which connects with a shaft 190 feet deep. H. L. Comstock is superintendent. At the Pac-tolus G. & C. Co. mine, of which H. L. Comstock is manager, an air shaft is being sunk to connect with a 500-foot tunnel that is being driven.

The millsite and concentrator of the Copper King G. M. Co. at Dawson was sold last week to T. S. Harris, of Canon City, by sheriff, to satisfy claims of men who built it, amounting to \$2500. The cost of the concentrator was \$16,000.

GILPIN COUNTY.

Most of the ore produced at the Gunnell and Grand Army mines, on Gunnell hill, near Central City, is being taken out by tributaries. The work is confined to the levels above the 1000-foot point, but work will be resumed in the lower levels next month. Shipments are being made from the Baby Ruth mine up Prosser gulch to the stamp mills. It is north of the Eureka shaft and operated by Allen & Co. of Central City.

At the International M. Co.'s P. K. mine on Silver gulch, near Black Hawk, men are straightening the shaft and sinking will resume next month. Eastern parties are working a group of twenty-four claims on Cyclops hill above the Hidden Treasure mill, which will be cut by the Reward and Alleghany tunnels. The Reward is in 150 feet.

Manager A. B. Drake of the Mingo G. M. Co. says the ore body was struck last week in the 300-foot level west of the Mingo mine in Lake district, showing 2 feet of concentrating ore and 12 inches of smelting grade carrying gray copper and lead ore.

The Helen G. M. & T. Co. have their tunnel on Colorado hill in Pine district in 275 feet.

Superintendent G. W. Mahee of the Butler Con. M. Co. on Gunnell hill says they will sink the shaft, now down 315 feet, another 100 feet. The shaft on the Belden mine in Chase gulch is being retimbered.

GUNNISON COUNTY.

In the Augusta mine at Pittsburg the tunnel at a depth of 1500 feet is in 2000 feet and is expected to cut the Augusta vein opened in the 320-foot tunnel which enters the mountain from the Dark canyon side. The upper tunnel is in 1200 feet. The last 100 feet of this tunnel is in a body of quartz carrying ruby silver and zinc blende and gold values. The Augusta Co. expects to complete the lower tunnel next month. A concentrating plant will

be erected and a 2-mile tram will connect the mine and the mill.

The Akron M. Co.'s tunnel under the May-Mazeppa and North Star ground in the Whitepine district is in 2725 feet and nearing the ore bodies opened in the upper workings which they expect to reach by April 1. The new shaft on the David H. is down 100 feet and they expect to cut ore at 125 feet.

The Good Hope mine at Vulcan is showing in the 500-foot level 3 feet of ore carrying tellurides and assaying \$500 gold. The shipments are forty tons per week.

The Headlight Co. at Spencer has its shaft down 100 feet and will continue.

LAKE COUNTY.

The Garibaldi tunnel at the head of California gulch near Leadville has resumed, under lease to J. Cooper.

The Walcott M. Co. has leased the Coronado property near Leadville to the Midas M. Co. This will give the Midas twenty acres further to the north. At the Best Friend, near Leadville, leased to McHale Bros., Lynch & Brooks, the tunnel now in 140 feet will cut the Doyle shaft 170 feet below its present bottom.

F. Lanphier & Co., operating the north end of the Fanny Rawlings claim near Leadville, have 2 feet of shipping ore in the shaft.

Superintendent J. Evans the New Home M. Co., Leadville, is shipping 100 tons per day of iron ore from the Penrose and doing development work.

Last week twelve hand roasters and another lead furnace were blown in at the Salida smelter at Leadville, giving it a capacity of 700 tons per day.

The Valentine workings are unwatered, it taking thirty days. The average flow of water raised was 1200 gallons per minute. Guides have been put into the shaft, a cage installed, and men are cutting a station at the 500 level for a compound pump.

The tunnel on the Best Friend is in 150 feet and another in 350 feet is expected to cut the Doyle vein. The tunnel will strike the shaft 170 feet below its present workings.

LA PLATA COUNTY.

The Bonnie Girl M. Co., near Durango, propose to install a cyanide plant.

OURAY COUNTY.

The Paymaster-Sylvanite M. & M. Co. is incorporated; H. Hobson, T. F. Nelson, A. B. Bradford and J. R. Farris, to operate in the Uncompahgre mining district.

PARK COUNTY.

Oil has appeared in the well of the Illinois-Colorado Oil, Gas & Coal Co., in South Park, at a depth of 125 feet.

During the past year 60,000 acres of oil lands were located in the South Park, around the Lone Tree spring, midway between Hartsel and Como, and in this section the first drilling experiments are being made. The People's Union Oil Co. of California and Chicago men has been organized to operate in South Park, and has 1000 acres of oil land.

SAN JUAN COUNTY.

(Special Correspondence).—The Sunny-side M. Co. has disposed of all its holdings to the Venture Corporation Co. of London. Stated price \$2,500,000.

Silverton, Jan. 22.

A. V. Shaw of Boston has a lease on the Boston-Auburn claims on Tower mountain near the summit on the Eureka gulch side, near Eureka. There are two tunnels and two shafts, making 400 feet of development.

SAN MIGUEL COUNTY.

The Liberty Bell's 50-stamp mill, one-half mile above Telluride, is crushing 300 tons of ore per twenty-four hours. The cyanide plant treats the tailings from the mill.

SUMMIT COUNTY.

The Puzzle M. & R. Co. of Breckenridge is putting a churn drill hole down from the shaft in Illinois gulch on the Puzzle Extension claim. The drill hole is to connect with an upraise driven from the Puzzle main tunnel. From the collar of the shaft to the tunnel level is 140 feet; the drill hole will drain the water from the shaft into the tunnel level, facilitating further development from the shaft, which is 110 feet deep. H. B. Achter is manager. The Mountain Pride is shipping 100 tons per month of ore and concentrates. It is a silver-lead ore carrying gold values.

The Nettle B at Kokomo, operated by P. Fisher, is shipping 500 tons per month of iron sulphide ore.

TELLER COUNTY.

Shipments from the Jerry Johnson, Cripple Creek district, amount to 130 tons a month, which average \$100. There are two sets of lessees. Welder & Co. are operating the Pullin shaft and are sinking

an additional 100 feet, which will give them a total of 1200 feet. They are stopping from the 300 level on a 4-foot vein that contains 2 feet of \$100 ore. Fogleman & Co. are operating through the Raine shaft. They are stopping in the 225-foot level and breaking 18 inches of \$100 ore; also drifting on this level.

Ardoll & Co., leasing on the main workings of the Dante, on Bull hill, Cripple Creek, are shipping a car a week of \$60 ore. The ground is being prospected at surface by other lessees.

Babbitt Bros., leasing on the Jenny Sample, on Raven hill, Cripple Creek, are shipping 100 tons a month of ore from the 200 foot level north of the shaft, and some from the 430-foot level.

H. P. Dahl has a lease on the Anaconda Co. mine, at Cripple Creek, in the lower workings. It is being worked through a winze, which is sunk 400 feet below the tunnel. The lease includes territory from 200-foot level of the winze down 300 feet. The top of the winze is at an elevation of 9500 feet above sea level, and the Cripple Creek drainage tunnel will cut the water at 8800 feet.

Work is resumed on the Amanda at Windy Point, near Cripple Creek.

Manager H. M. Risley of the Frank Burt M. & Co. on the north side of Iron mountain, 2 miles northeast of Cripple Creek, has the shaft down 60 feet and in ore carrying gray copper, copper glance and cuprite with gold. The shaft will be sunk another 100 feet. West of Iron Mountain the Denton G. M. Co., owned by Cleveland, O., men, is driving a tunnel on the Denton claim which in another 100 feet is expected to cut a vein opened up 200 feet higher up the hill assaying \$100.

Manager D. Hanley, the Cripple Creek Enterprise M. Co., mining under the streets of Cripple Creek, last week struck a flow of water in the shaft at 200 feet, and pumps are being put in. — Returns from the Whetstone lease on the Morning Glory claim of the Work Co. last week gave \$37 per ton for a 10-ton shipment, and \$31 per ton for a 25-ton lot.

A strike of gray copper ore has been made in the bottom of the winze 300 feet below the 900-foot level of the main shaft of the Rubie claim on Bull hill, near Cripple Creek.

A cyanide plant is being installed on the Adonis claim on Copper mountain, Cripple Creek district, under lease to the Sioux Falls & Cripple Creek G. M. Co. O. B. Finn is superintendent.

The Anaconda Co. at Cripple Creek has granted a lease to C. Crowder & Co. on blocks 25, 26, 27, 18 and 19, on the northeast slope of the Gold side. On account of bad air at face of the main tunnel the operators will drive one of the main laterals 400 feet to connect with the tunnel. From the Mercer lease on block 34, 100 tons of \$30 ore are shipped monthly.

Gilbert & Sayle, leasing on the LeClair on Gold hill, Cripple Creek district, have the shaft down 140 feet and will go to 400 feet.

The directors of the Stratton-Cripple Creek M. & D. Co. have decided it is impracticable to grant leases of the ground as it lies at present, as the claims are too large to be leased to any one person. All their territory will be surveyed and apportioned into blocks before any leases are considered. There have been received 600 applications for leases.

B. Fuller, leaser of the Gold Coin dump, is refitting the Beatty sampler, near Goldfield.

The Cripple Creek & Pueblo Ry. Co., which bought the Gold Exploitation tunnel (Ophella), which enters Gold hill from Cripple Creek, has begun operations. Manager Parfett says it is in 6000 feet, and after connections are made for air with some of the adjoining properties, they will drive ahead for 3 miles into Bull hill which it will cut at 1600 feet below the apex. The tunnel is equipped with an air compressor and other machinery, and it is expected to make 10 feet a day.

The Dan Hanley shaft of the Cripple Creek G. E. Co., near Cripple Creek, is down 200 feet and a station cut.

A washing machine has been put in at the Granite mine on Battle mountain, near Cripple Creek, to clean ore before it goes on the sorters' table. It has a capacity of 200 tons daily.

Sinking is resumed on the Zoe on Beacon hill, near Cripple Creek, by lessees Hanson & Best to go another 75 feet. The shaft is down 600 feet. This leasing company did not sink last year on account of water, but since the El Paso Co. has been pumping the water has receded in the Zoe ground.

IDAHO.

BOISE COUNTY.

The Lost Packer mine on Loon creek, owned by a New York company, has been tapped at a depth of 100 feet. The ledge is $4\frac{1}{2}$ feet wide and the ore runs \$37 in gold, says the Idaho World.

CUSTER COUNTY.

Two carloads of ore from the Ramshorn mine at Bay Horse, operated by lessees, were marketed last week.

IDAHO COUNTY.

The Lucky Lad and Alligator claims, north of the Big Buffalo, in Buffalo Hump district, are sold to G. L. Hedges of Seattle, Wash., for \$45,000. A tunnel will be driven.

Manager R. M. Sherman says the first week's run at the American Eagle 10-stamp mill, near Elk City, gave two gold bars worth \$3180. The ore crushed was from the three stopes of the upper tunnel. Twenty tons per day are crushed.

The Fortune mine in Buffalo Hump has been bonded to R. H. Hughes for \$55,000.

OWYHEE COUNTY.

At the Hoosier M. Co.'s group, near Silver City, two tunnels are being run, one on each side of Barnes' gulch, by Contractor J. Jensen; tunnel No. 7 on the east side 1500 feet and on the west side tunnel No. 3 of 700 feet.

SHOSHONE COUNTY.

On the Stewart property, near Government gulch, near Wardner, the prospect tunnel has cut a body of carbonate ore.

It is reported that mines in the Cœur d'Alene district have contracted to deliver 800,000 tons of lead ore to the Independent smelters during a period of five years.

WASHINGTON COUNTY.

Last week the smelter of the Boston & Seven Devils C. Co., on the Welser river, 8 miles from Welser, was sold to C. A. Ballerich of Denver, Colo., on a \$24,000 judgment for machinery furnished.

MICHIGAN.

HOUGHTON COUNTY.

The shaft on the Ahmeek mine, near Houghton, is down 100 feet. Sinking has been stopped and a Highland Jumper drill is prospecting from the bottom of the shaft. The property consists of 920 acres northwest of the Mohawk. The formation dips at 38° and the drill hole is expected to show up the Kearsarge lode.

The Quincy at Houghton will put in ten additional electric tramming locomotives. The experience of the past year with the four now in use on the forty-third, forty-sixth, forty-ninth and fifty-fifth levels, north of No. 6 shaft, has proven their economy. It is the intention of the management to do away with all hand tramming. They will install a 1200 H. P. electrical generating plant to furnish light for the mill and mine and power for the locomotives at the mill at Mason, where it has its fuel docks.

The steam cylinder and upright frames for the third head of the Trimountain mill, near Houghton, are being set up and the balance for the third and fourth heads have arrived. The plant is expected to be completed by March 1st. The Trimountain began stamping Jan. 3, 1902, with the leased Arcadian head. On Nov. 1 two heads in its own mill were stamping; 200,000 tons were crushed for the year.

The Calumet & Hecla, near Houghton, is stamping 6000 tons of rock daily.

The tailings are being worked over at the Franklin copper mine mill, and a concentrating plant for a similar purpose is being built at the Central mine.

MISSOURI.

JASPER COUNTY.

During the year 1902 there were slight changes in mining methods, and the general situation both as to mining and milling in the Joplin district shows but small variations from the practice of 1901. The only change in mining practice is the employment of heavier hoisting devices and buckets of larger capacity; 1000-pound buckets have been added to the new plants in place of the 500-pound buckets formerly used. This has necessitated heavier cables and stronger hoisting engines. The number of air drills used has increased during the year. Few mills have been built during the year, but a large number of old mills have been moved to new locations, and the number of operating mills is about the same as a year ago.

The production of spelter during the year 1902 is estimated by J. Struther, compiler of the spelter statistics for the U. S. Geological Survey, at 153,447 tons, or 17,595 tons greater than the production of the preceding year. The spelter production of the United States in 1891 was 80,873 tons; since then the production has been almost doubled, the actual increase since that year being 98%. From 1891 to 1897 the production did not exceed 81,499 tons. The following year the production was almost 100,000 tons, and since then the production has increased more than 50%.

MONTANA.

DEER LODGE COUNTY.

At the Atlantic Cable mine, at Cable, the shaft has been unwatered and development begun, with twenty men at work. At the head of Flint creek the Milwaukee G. E. Co. has twenty men at work on the Hannah claim. G. H. Savage is superintendent.

FERGUS COUNTY.

The capacity of the Kendall mill at Kendall will be increased by eight more tanks next month, which will make a daily output of 400 tons, says Superintendent H. Lang.

FLATHEAD COUNTY.

D. P. Bowers, manager of the Snowshoe, near Libby, owned by the Rustler M. Co. of Spokane, Wash., says that a strike of 2 feet of shipping galena has been made. "During the past year we have milled ore taken only from development in sinking the winze and in driving the drift, little stoping having been done. We sold \$60,000 worth of concentrates to the smelter. It cost \$26 per ton to get our ore treated, including hauling by team to Libby, giving net returns from the smelter of \$40,000. During the summer the mill was run but 125 shifts. We will increase the capacity of the mill to 300 tons a day, and put in additional power either with a flume or electric plant."

GRANITE COUNTY.

A strike is reported in the west 1700-foot level of the Bimetallie mine at Granite of ore assaying 1500 ounces silver. The ore carries ruby silver with native silver.

MADISON COUNTY.

Last week W. B. Millard bought of C. E. Damours one-sixth interest in the bond of the Kearsarge lode, near Virginia City, and his holdings in the Sparling properties, for \$2500. Millard also bought the interests of the Pomeys and the J. Hyde estate, making a total of \$10,000 involved. The Madisonian says in the Shenandoah mine, near Virginia City, owned by G. F. Weeks, an 18-inch shoot of gold ore has been opened, assaying \$75.

On the Easton and Pacific mines, near Virginia City, there are forty men at work.

The Kennett Co. last week shipped \$10,000 in gold bullion as a result of twenty days' run of the 5-stamp mill, working two-thirds of each day. The ore was from the Kearsarge mine at Summit, near Virginia City. R. B. Turner is superintendent.

PARK COUNTY.

Butte men have an option on the Yellowstone M. Co. mines in Bear gulch, adjoining the ground of the Bear Gulch M. Co., near Livingston.

SILVER BOW COUNTY.

For several months past the Anaconda Co. has been making an effort to solve the smoke problem in Butte, and scientific experiments have been in progress at the new smelters at Anaconda under the direction of Stuart Croisdale, of Colorado, and the construction of dust chambers and other additions to the smelting plant, which are expected to eliminate the smoke trouble, will soon be begun.

F. A. Heinze, as administrator of the estate of J. Larkin, has petitioned the court to lease to him the mining claims of the estate for 25% of the ore extracted.

President L. Mantle of the Butte M. & D. Co., operating the Emma in the southern part of Butte, says the crosscut at the 800 is in 485 feet, 150 feet of which is in the lead. One ore body cut is 5 feet wide and shows an average of twenty-five ounces silver, \$3 gold, 14% lead and 1% copper.

NEVADA.

DOUGLAS COUNTY.

E. W. Carmen, of Cleveland, O., has bought the Longfellow mine in Red Canyon district, half a mile from Bullionville, near Gardnerville, for \$3000. A mill will be built.

ELKO COUNTY.

The mines at Bull Run employ thirty-five men.

The Bull Run mine in Centennial district has been sold to H. P. Taylor, of Boise, Idaho, for \$150,000.

HUMBOLDT COUNTY.

(Special Correspondence.)—The California-Nevada M. Co. of Los Angeles, with mines at Lovelock, are developing an 8-foot vein in the Victor mine. The company is installing a mill furnished by John Wigmore & Sons Co., consisting of three Standard concentrators and a Sturtevant mill. More concentrators will be put in.

J. A. Lathrop of Boston, Mass., reports having an option on the Rye Patch mine, near Lovelock.

Lovelock, Jan. 20.

Diamond drills will be used by the

American Nickel Co. at their properties in the Cottonwood district in prospecting. G. W. Dunn is president.

LINCOLN COUNTY.

At the Demijohn mine, near Pioche, near the Half Moon, a raise hack of the shaft has been connected with the lower workings, showing up a body of lead-iron ore and providing a current of air.

C. O. Whittemore & Co., of Salt Lake City, Utah, have an option on the Mendha group at Highland district. In the lower workings the Navy drift shows 6 feet of gold ore.

The Keystone Co., with their Huntington mill at Sandy, is said to be netting \$10,000 per month.

Superintendent Drummond says the preliminary surface work, setting up machinery, etc., is completed and development begun in the Good Hope mine at Searchlight.

Mayhew, Alexander, Cohn and Miller are working on a contract for the Duplex Co. near Searchlight, running a 600-foot crosscut from the 500 level in the main shaft of the Searchlight to the New Year's Gift. The ore road to the mill is finished to the New Year's Gift shaft and will be continued to the Ella workings. A three-terrace tailings pond has been laid out below the mill.

Superintendent C. Gracey of the Wall Street mine at El Dorado Canyon has the shaft down 105 feet and in ore.

The tailings dump around the old De Lamar mill are yielding bullion returns of \$2.25 gold per ton, says Superintendent F. P. Janney. There are 700,000 tons in the dump and 200 tons are daily cyanided. On construction and underground there are 600 men at work.

At the Mendha, near Pioche, Superintendent T. J. Osborne is opening up the ledge, which averages \$30 in gold.

NYE COUNTY.

(Special Correspondence.)—The Montana-Tonopah has good milling ore on the dump and a new strike of high-grade ore is reported in their shaft at 450 feet. The Great Western shaft is down 110 feet with horse whim. The new hoist on the Hallfax is running. The shaft is down 320 feet. The California-Tonopah shaft is down 190 feet. Manager Sollender reports 30 feet of ore, 4 feet of which is shipping grade. The Fraction Co. are taking out ore from their new strike in No. 2 shaft. The Ohio-Tonopah shaft is down 465 feet.

On the Gold Hill they are cutting a station at the 300 level; when completed they will sink to 500 feet and connect with the Tonopah M. Co.

The Silver State shaft is down 575 feet. A strike was reported of 7 feet of \$60 ore. The Tonopah Midway Co. have begun sinking with their new steam hoist.

The King-Tonopah Co. (Lynch & O'Meara) are down 110 feet with a gasoline hoist. A strike is reported in the Wandering Boy shaft of the Tonopah & Salt Lake Co. The Tonopah Co. continues development work, but no stoping is going on.

The Mizpah Extension Co.'s shaft is down 612 feet. In sinking the sump for crosscuts the showing determined the management to crosscut at this level and continue sinking. They are coming into another ledge. The Osborne mill at Butler wells is running on Tonopah ores.

The Ray & O'Brien Co. at Ray are down 300 feet, with 2 to 4 feet of ore—some shipping.

The Silver King at Lone mountain is sinking on a vein 7 feet wide, of which 8 inches on the hanging wall goes \$6 per ton in silver; the balance of the vein goes \$8.

Tonopah, Jan. 19.

The Tonopah Cash Boy Co. is incorporated, J. D. Torreyson, L. A. Blakerley, A. G. Fletcher, H. J. Humphries, A. Wise, M. W. Smith, C. J. Young, J. G. McGuire, C. A. Clinton, T. R. Bannerman and J. Ryan, to operate properties joining the Tonopah, Little Tonopah and Golden Anchor, at Butler. The Giant Tonopah Co., 5 miles north of Butler, are taking out \$20 gold ore from their shaft, which is down 35 feet. Osborn's mill at Butler's wells is in operation. Ford & O'Neil, working a group of claims on Lone Mountain, have opened up a 4-foot ledge of galena running 20% lead, thirty ounces silver and a little gold.

At the Golden Anchor, at Tonopah, adjoining the Mizpah on the west, the shaft is down 110 feet, and in gray porphyry containing seams of quartz carrying values. The working shaft is 4 feet 4 inches square, with a 2 foot manway. Manager F. Ish, the North Star M. Co., says the main shaft is down 550 feet. The machinery for the hoist is on the ground. The Ohio-Tonopah shaft is down 475 feet and in the porphyry. A double-compartment shaft is being sunk by the Indiana-Tonopah on the Owl claim.

Sinking on the Molly Co. shaft, near Butler, is going down at the rate of 12

foot per shift. The shaft is double compartment, 10x4½ feet clear. The timbers are 8x8, and lagging 2x12.

The Tonopah Co., at Butler, is shipping 6000 sacks of ore monthly, which is being extracted in development work. Ore is being raised from the Silver Top shaft, at the southern opening of the company mines. The Desert Queen shaft last week cut seams of ore considered to show the proximity of the ledge. The Selbert shaft is 50 feet below the 500 station. The steam hoist at the Midway of the Midway-Tonopah Co. is in operation. At the Tonopah City, a steam hoist is being set up. At the McNamara, the boiler and hoisting engine are being put in place.

STOREY COUNTY.

The following is a report of the work at the mines of the Comstock at Virginia City for the week ending January 17th: Total extraction of ore for the week at the Con. Cal. & Virginia, nine cars, assaying on a basis of gold value \$52.88, and 161 cars assaying \$21.13 per ton. At the Ophir, 1900 level, the north drift from the fourteenth floor was driven from the north side of the slope 12 feet; total length, 50 feet; face in low-grade ore. The north drift from the sill floor was driven 17 feet; total length, 112 feet; face in hard porphyry and stringers of quartz. At the Hale & Norcross the tunnel was driven 13 feet; total length 3389 feet, with the face in diorite. At the Sierra Nevada, 1600 level, the north lateral drift started from the joint Sierra Nevada and Union west crosscut, 294 feet in, was driven 10 feet through porphyry and clay; total length, 58 feet. On the Best & Belcher, 200 level, the east crosscut No. 1 from the south drift was driven 20 feet; total length, 92 feet. The north drift from the raise was extended 11 feet through quartz; total length, 55 feet. The main south drift was extended 19 feet through low-grade ore; total length, 116 feet.

WASHOE COUNTY.

E. Olinghouse last week milled twenty tons of \$65 ore from his claims at Olinghouse. He has 100 tons on the dump valued at \$40 per ton. W. C. Williams' mill is running on ore from the Cabin and Gold Ledge.

NEW MEXICO.

COLFAX COUNTY.

The Confidence M. Co., at Elizabethtown, is crosscutting from the 400-foot level with three shifts.

The Baldy tunnel property of the G. & C. Deep Tunnel M. & M. Co. in Big Nigger gulch, near Elizabethtown, has put on another shift. The tunnel is in 820 feet and will be run 3600 feet in all, giving a depth of 2000 feet.

The Confidence M. Co. is crosscutting from the 400-foot level, with three shifts at work. The Bobtail-Senate mine will resume under new management.

GRANT COUNTY.

The tunnel on the Manhattan at Pinos Altos is being cleaned out preparatory to resuming.

G. Easton, leasing the Caldwell group at Burros, is shipping copper ore to the smelter. The Silver City smelter has been sold to the Comanche M. & S. Co., which will increase the capacity to 250 tons per month. R. H. Thompson has begun development work on the McKinley mine in the Burros district. He has put up a whim and is sinking. The McKinley adjoins the St. Louis of the Southwestern C. Co. C. P. McLaughlin is developing copper property at White-water in the Burros and putting in a steam hoist.

Operations have begun on the Hirschberger mine at Pinos Altos. J. L. Schofield & Co. have a bond on this property, consisting of the Eastern and Western, adjoining the Mountain Key mine. The Eastern is developed by four shafts from 40 to 160 feet deep which are in ore. There are four shafts on the Western, the main shaft being down 340 feet with 2000 feet of drifts and crosscuts. The lessees have erected a steam hoist and are unwatering the workings.

SAN JUAN COUNTY.

H. Towner and T. Bryan are reported to have a 30-foot vein of lignite coal on their claim near Fruitland.

SANTA FE COUNTY.

C. R. Galbrath and C. G. Warner of Franklin, Pa., have bought a group of claims at Cerrillos, including the Great Western, Robert G. Ingersoll, Sure Winner, Bertha Mable and Little Chief, for \$7000. They are interested in the smelter at Cerrillos.

SIERRA COUNTY.

C. H. Laidlaw has five men at work on the Black Knife group at Fairview. Men are working on the Dictator group

at Fairview, which is owned by Pittsburg, Pa., men.

The Prosper G. M. & M. Co., at Fairview, will put up a mill and hoist.

The Hillsboro G. M. & M. Co. has resumed at its mill in Ready Pay gulch on ore from the Ready Pay mine.

B. S. Phillips will move the Wing mill from Mineral creek to the Minnehaha mine at Fairview.

TAOS COUNTY.

The New Mexican says Cripple Creek parties will put in a dredger at Questa this spring.

OREGON.

BAKER COUNTY.

Manager P. R. Bishop of the Climax mine, near Sumpter, says he has finished sinking a 60-foot winze from the upper tunnel. An upraise being driven from the lower tunnel to meet it is up 50 feet, with 100 feet yet to go.

Manager Bellman says the aerial tramway at the California mine near Sumpter is in operation.

A. H. Willett, of Portland, has bonded the Hawkeye group, being the Hawkeye, Mikado, Bromo-Chloride and Modoc claims, near Quartzburg, for \$18,000.

W. W. Robbins, of the South Pole Con. M. Co. on Rock creek, 8 miles from Sumpter, says the tunnel is in 860 feet.

Manager A. B. Brown, the Yellow Daisy mine near Sumpter, says the adit tunnel is in 320 feet, following vein matter. This group of six claims is on Spokane mountain, across Clear creek from the Red Boy mine, and adjoins the Blue Bird on the southeast.

Twenty stamps are dropping in the mill of the North Pole Co., near Sumpter. There will be forty stamps in operation when the mill is completed. The California mine has temporarily closed down.

Superintendent Thorpe, the Blue Bird, near Sumpter, has men drifting from the crosscut on the second vein. Development has thus far been mostly on the third vein. The drift on the third vein has shown a series of faults.

GRANT COUNTY.

L. Steinmetzer has a contract for 80 feet of tunnel along the ledge at the Strassburg, near Alamo.

Sexton & Ward, at the Little Klondike at Quartzburg, have run a 50-foot tunnel and cut a 4 foot ledge of quartz containing galena and gold.

The George Washington mine, near Quartzburg, owned by Ward Brothers & Sexton, is being opened by a tunnel in 275 feet. On the Oakland there is one vein 3 feet wide and another one 20 feet, being opened up by two tunnels 300 and 325 feet in length. There are several open cuts and shafts on the veins.

JACKSON COUNTY.

The Maybelle mine of the White Cross M. Co., near Gold Hill, was sold by the sheriff last week to C. Wetherell on a judgment.

W. Nash has sold part of his mining ground in Grave Creek district to J. D. Heard, C. Strang, W. S. Jones and F. King, who will cut a ditch and begin development.

JOSEPHINE COUNTY.

The Gold Mining King group of claims, on Josephine creek, in western Josephine, has been bonded by M. Marks of Seattle, Wash., for \$10,000; he will put up a mill.

MALHEUR COUNTY.

Manager J. F. Meikle, of the Black Eagle M. Co., has the 20-stamp mill crushing ore from the porphyry dike, near Malheur.

SOUTH DAKOTA.

LAWRENCE COUNTY.

Since Nov. 1, 1902, the capacity of the mines of this county has been increased to a total monthly tonnage of 51,300 tons, the last of the plants being completed this month. Following is a statement showing the monthly capacity of the several companies:

	Tons.
Horseshoe	30,000
Hidden Fortune	7,500
Penobscot	6,000
Hall & McConnell	1,800
Jupiter	4,500
Golden Crest	1,500

Total tonnage.....51,300
The 200-hp air compressor at the Ellison shaft of the Homestake M. Co., at Lead, is in operation.

The Pluma G. M. Co., near Lead, while excavating for the addition to the 40-stamp mill, struck ore of milling grade in two veins, aggregating 70 feet wide. The discovery is on the company's millsite of nine acres 4000 feet from the mine. The Pluma Co. controls the two veins cut for 900 feet on their strike. The main Pluma

shaft, in northeast Lead, is 410 feet deep, and in ore for 200 feet. On the 300 level a crosscut has been driven 150 feet west, opening up a body of milling ore. This crosscut is heading for the Hawkeye shaft, on ground bought by the Pluma Co.

The Columbus Con. M. Co. has completed the addition to its mill in Gayville, giving it a daily capacity of 100 tons.

TEXAS.

EL PASO COUNTY.

Last week at El Paso Chamberlain and Mote of San Pedro, Mexico, in the double-handed drilling contest for a purse of \$1000, made 43½ inches in fourteen minutes. The rock used was a block of Gunnison, Colo., granite. In the single-handed contest F. Yockey of Boulder, Colo., won by drilling 23½ inches in fifteen minutes.

UTAH.

C. DeMoisey, State Statistician, gives the following production of metals in Utah during 1902:

Silver, 15,173,204 ounces, at .5217 cents per ounce, \$7,915,338.83.

Gold, 193,865 ounces, \$20.67 per ounce, \$4,007,189.55.

Lead, 132,852,462 pounds, 4 cents per pound, \$5,314,098.48.

Copper, 26,824,153 pounds, 11.76 cents per pound, \$3,154,520.39.

During the year, 1883 men were employed in the mines, and \$5,025,500 in dividends were paid. After deducting for machinery and improvements, the net profit on all the mines in the State was 25%.

BEAVER COUNTY.

Four 34 H. P. gasoline hoists will be installed by the Majestic Co., at Milford, at the O. K., Harrington-Hickory, Vicksburg and Old Hickory.—At the O. K. a strike of sulphide ore is reported on the 200 level.—At the Vicksburg the new shaft is down 130 feet. At 250 feet a crosscut will be run to the vein.

In the Star district, near Milford, C. E. Rives has an option on the Beacon claim, at Shauntie, for \$12,000, to be paid in nine months. The property is ¼ mile from the Burning Moscow and is considered on the same ledge. Rives also has an option on the Anvil and Old Crow for \$12,000.—The Bluebird Co. has an option on the Hobson and Helen groups of eighteen claims, near the Copper King, for \$30,000.—The Majestic Co. has bought from D. Williams the Missionary claim, between the Old Hickory and Index groups, both of which are owned by the Majestic.

Fotheringham, McAulay & Lindsay, sinking a shaft on their group of claims southeast of the Majestic Co.'s Old Hickory, are down 70 feet in copper ore cut at 43 feet.

M. M. Jacobsen and F. Bettles, of the Cactus group near Frisco, report gray copper and chalcopryite in the west workings, assaying 20% copper, 25 ounces silver, and \$3 gold. The shaft has been unwatered.

GRAND COUNTY.

The Westwater Oil & A. Co. will install an asphaltum refinery of 100 tons capacity. The company owns 480 acres near Westwater, on which are deposits of crude asphaltum near the surface, which can be quarried.

IRON COUNTY.

The mines and mills of the Ophir M. Co. at Stateline are closed down.

JUAB COUNTY.

Ore is reported in the Early Harvest group at Fish Springs, in the Deep Creek district, assaying 156 ounces silver, 15% lead and 4.5% copper at a depth of 18 feet.

In the lowest workings on the Utah of Fish Springs, in the Deep Creek country, Superintendent C. Crismon says he has opened up ore that shows 446 ounces silver, with 30% lead.

The annual report of Secretary Bean to the shareholders of the Lower Mammoth Co. of Tintic showed that the company has sold during the fiscal year 3640 tons of ore averaging \$22.87 per ton. The gross receipts were \$83,258.25 and the disbursements \$76,698.66.

A body of sulphide ore carrying values in lead, silver and gold was opened in the Little Chief mine, Tintic district, last week, in a raise above the 800 level.

Manager C. E. Allen, the Centennial-Eureka, Tintic district, reports 225 tons of ore passing daily over the tramway to the furnaces of the United States smelter.

MILLARD COUNTY.

The Burns oil rig, near Deseret switch, has resumed and is down 1175 feet. It is intended to go 2000 or 3000 feet.

PIUTE COUNTY.

L. Nielsen & Co. will resume operations on the L. & N. group of fifteen claims on

the line separating the Baldy and Ohio mining districts, near Marysville. The lower tunnel is in 225 feet and is expected to cut the ore body at 500 feet. At one point a shaft has been sunk in ore giving assays of \$10 gold and silver. East of the L. & N. is the Elephant group, with the Wedge adjoining. P. A. Franklin has bought the Mountain Queen from Reynolds, Lyon & Balor. He also owns the Mount Baldy group of thirty claims and has an option on the Wedge.

SALT LAKE COUNTY.

At 4200 feet the Franklin tunnel, near Bingham, has cut the Silver Shield vein, reports Manager Joseph. It is 5 feet between walls, shows two streaks of ore.

The Cottonwood tunnel (Bingham and Eastern group), following the Jersey Blue fissure, near Bingham, is in 1920 feet. According to survey, at 1945 feet it will cut the IXL vein.

The lower or main tunnel of the Boston Con. of Bingham has cut through an ore-bearing zone 80 feet between walls and is going ahead for the main ore bodies. This ore carries iron sulphides, with values in copper, gold and silver. The chute was cut at 1000 feet on the dip of the vein.

At the Commercial group, near Bingham, the lead fissure has been opened up for 55 feet along its strike, the ledge being 4 feet wide, and has been raised on for 15 feet. From the Commercial 225 tons of sulphide ore are taken out daily and at the Dalton & Lark seventy-five tons. The main drain tunnel on the Dalton & Lark group is in 5200 feet and 400 gallons of water per minute are coming out at the opening.

It is reported the Pioneer sampler at Sandy is to be repaired and operated by a company, of which L. O. Jensen is manager.

Superintendent W. H. Nutting of the Bingham Con. Co.'s furnaces at Bingham says, with reinforcements that recent changes have provided, a reduction of 3 mills per pound is made in the cost of producing bullion. At present 500 tons of ore daily are being treated with three furnaces.

SEVIER COUNTY.

The lower tunnel of the B. W. & H. mine, in Henry district near Richfield, has tapped a 3-foot vein of shipping ore which is being sacked.

SUMMIT COUNTY.

Manager Lawrence of the Scottish Chief mine, above Park City, says he is shipping ore to the smelter assaying 40% lead, thirty ounces silver and \$2 gold.

Foreman Getsch, at the California mine at Park City, says the lower tunnel is in 1630 feet, the shaft is down 100 feet, and as soon as the tunnel level is reached (180 feet) the company will put up hoisting works and continue sinking to 500 feet. The vein in the upper workings is 60 feet wide, which averages half ore and half shale.

The tunnel at the Park City and Mid-night Sun mines in Iron canyon, near Park City, is in 450 feet, and is thought to be on the contact.

The shaft at the American Flag, near Park City, Superintendent Rhodin says is down 220 feet.

Manager A. L. Dickerman has the zinc plant at Park City in operation.

Manager Sappington, the Superiormine near Park City, reports a strike of silver-lead ore at 1350 feet in the tunnel, the values occurring in black manganese oxide. The company has nine patented claims in Bonanza Flat.

TOOELE COUNTY.

The Sacramento M. Co., at Mercur, has built furnaces for the reduction of the cinnabar in their ores. These ores have long been recognized as gold ores, with cinnabar as an accompaniment, and have been successfully worked by the cyanide process. The Sacramento is the first mine of the Camp Floyd group producing cinnabar in commercially profitable quantity.

UTAH COUNTY.

Elaterite (mineral wax) is reported by the Utah Shale Co. from their camp at Tucker. This hydrocarbon was found in a fissure cutting across the main deposit of shale, in which the men have been working preparatory to the setting up of the retort. The material is used for varnishes, insulation, etc. Manager Hague will exploit the deposit.

WASHINGTON.

FERRY COUNTY.

Superintendent Delbridge, the California mine, near Republic, says since July 15, 1902, in addition to the lead and copper, the mine has produced 3670 ounces of gold and 4650 ounces of silver, value \$75,000.

At the Belcher, on Upper Lambert Creek near Republic, two men are drifting on the vein, which carries \$32 gold. This

ore is practically self-fluxing. Contractor E. H. Clark is driving the tunnel ahead at 3 feet per day and is in 250 feet. At the Hawkoye copper mine, a mile west of the Belcher, the incline shaft 240 feet deep is being unwatered.

J. F. Lansing has a bond on the Blue Horse mine on Iron mountain, near Republic, and is sinking the shaft to 150 feet.

STEVENS COUNTY.

The Jefferson Marble Co. on Clugston creek, near Colville, is shipping its product to Chicago. The Crystal Marble Co. is also cutting and shipping material.

WYOMING.

During the last two years there were filed with the Secretary of State 339 mining corporation papers.

CARBON COUNTY.

The Verda Lode and Verde Lode Nos. 1, 2, 3 and 4, near Riverside, in the Douglas Creek mining district, have been sold to the Verda Con. Co. for \$100,000.

CROOK COUNTY.

The coal fields 10 miles west of Sundance, between Beaver and Inyan creeks, are to be opened up by the Black Hills Syndicate; and a railroad will be built to connect with the Burlington at Upton and at Spearfish, S. D., and with the Elkhorn at Bellefourche, S. D. C. Twombly is manager.

SHERIDAN COUNTY.

A strike is reported from the headwaters of Big Goose creek, near Sheridan, by C. W. Noyes and J. D. Watts. Their analyses shows uranium, gold, nickel and platinum.

UINTA COUNTY.

The Michigan-Wyoming Oil Co. at Spring Valley have resumed.—The Carter Co. are drilling.—The Atlantic & Pacific Co. is drilling on Section 24, Spring Valley. The first well is capped, all the tankage being full.—The American Con. O. Co. has resumed drilling on Section 34, and is now down 1080 feet and in the oil sand.

FOREIGN.

AFRICA.

GOLD COAST.

According to the recently issued colonial office report, gold is widely diffused throughout the colony, Ashanti and the northern territories, in quartz and alluvial deposits, while in Wassau there is gold-bearing conglomerate (bancet). The lack of good roads and means of transporting heavy machinery has proved an obstacle to successful mining on a large scale in the past, but the mining enterprise is resulting in improvement in the road system, and the Sekondi-Kumasi Railway overcomes the difficulty of transport to the Wassau district. The following table shows the amount of gold exported in 1901 and in each of the four previous years: 1897, 23,544 ounces (£84,797); 1898, 17,732 ounces (£63,838); 1899, 14,249 ounces (£51,300); 1900, 10,557 ounces (£38,007); 1901, 6162 ounces (£22,187). During the year 2825 concessions were filed in the colony, forty-one orders for survey were issued and two certificates of validity. Thirty-two prospecting licenses were issued and five prospecting licenses were converted into mining licenses. The number of surveyors' licenses issued was forty-four.

The population of the colony and Ashanti taken during the year was found to be 1,486,433, exclusive of the northern territories. The public health for the year was bad both in the European and native communities. Fifteen officials died during the year of a total of 188 and eighteen were invalided. Thirty-eight non-officials died and fifty-nine were, it is estimated, invalided.

SOUTH AFRICA.

For four months in succession the management at the Wolhuter has made a record in incline shaft sinking on the Rand, says the Johannesburg Star. The depth sunk, cleared and timbered was 209 feet. Between August and November the rate of progress has been advanced by nearly 30 feet, or nearly 17%. The work has been done entirely by white labor on contract, the men employed comprising skilled men and unskilled white helpers. The record of feet attained for the four months is: August 179 feet, September 182 feet, October 204 feet, November 209 feet. The shaft is in the eastern deep level section of the property and had reached a total depth at the end of November of over 1500 feet.

AUSTRALIA.

WEST AUSTRALIA.

The gold exported from West Australia and received at the Mint during December amounted to 189,755 ounces, valued, after refinement of the Mint's

portion, at \$692,605. The total production for the year ending December 31st amounted to 2,177,441 ounces, as compared with 1,879,390 ounces last year and 1,580,950 ounces the year before. The total yield since 1886 amounts to 11,982,049 ounces, valued at £37,670,371.

A gold rush to the newly discovered reefs at Bumbaldry, near Cowra, is in progress. The main line of reefs has been opened by trenches for 4 miles and is gold bearing all the way. A company has been formed to erect a mill. Some of the ore is rich.

The Golden Fleece mine, at Wyalong, is yielding rich pyritous ore. The Ali Nations mine is yielding 24-ounce ore and Neeld's mine 5-ounce ore. Two hundred and thirteen tons of ore crushed at Sully & Co.'s works for a number of small claim holders returned 670 ounces gold. A number of new mines are being opened on the field, and some Charters Towers men have two large leases adjoining the Neeld's mine and propose sinking to strike the reefs on the underlie. It is estimated that the shafts will have to be sunk to a depth of 4000 feet before the first reef is met.

BRITISH COLUMBIA.

Statistics of Provincial Government Office, Grand Forks, for calendar year 1902:

	No.	Revenue.
Free miners certificates.....	427	\$2,070 25
Companies' certificates.....	3	300 00
Special certificates.....	6	90 00
Certificates of work.....	580	1,510 00
Records of location of mineral claims.....	177	442 50
Conveyances.....	137	360 20
Certificates of improvements.....	51	127 50
Permission to relocate.....	1	12 50
Filings.....	70	17 50
Water rights.....	2	46 50
Miscellaneous receipts.....		308 30
Fees for crown grants passed through office.....		1,275 00
Total.....		\$6,560 25

The Blue Jay property, in Skylark camp, is negotiated for a working bond and lease for \$10,000. It is 1½ mile from Phoenix, on the same ridge with the Old Ironsides and Knob Hill mines. According to the terms of the lease, work on the Blue Jay must be continuous. It has a shaft 115 feet sunk on the ledge, and another shaft 40 feet in depth. A tunnel to tap the main shaft at a depth of 75 feet is now in 60 feet.

The Montreal & Boston Copper Co. will put in a converter at its smelter at Boundary Falls. Its second furnace will be running as soon as the blower has been received and put in place.

An electric hoist is being put in at the Snowshoe, the first electric hoist to be placed in Boundary district. Last week the Snowshoe sent out 1440 tons to the smelters. The last record was 1400 tons in one week in December.

On Saturday, the 17th inst., the Granby smelter blew in two furnaces, after a short shutdown on account of fire in the power and blower house. But for shortage of coke all four furnaces would be running. Two new furnaces will be put in, the full equipment to be completed by March, 1904. The week before last four furnaces treated 10,115 tons of ore at a cost, including freight and commission, of \$2.65 per ton. The management says it expects to reduce this to \$2.50. The company is putting in a 60-drill compressor. G. M. Luther is general manager.

The ore shipments from the Nelson division in 1902 amounted to 70,000 tons, as against 109,226 tons for 1901. This is valued at \$580,000, or about one-half of that credited this division by the Provincial Mineralogist for 1901. The drop in silver, copper and lead is responsible, and many properties have been compelled to close down or worked intermittently. The Ymir mine output was 50,000 tons, of a gross value of \$340,000. About 3400 tons of concentrates were shipped, the average value being \$30.

Ore is being broken in the stopes of the second and third levels of No. 1 mine of Le Roi No. 2. In the Josie the work of undercutting the ore bodies cut off by the dike is in progress.

The Homestake mine, near Rossland, has resumed shipping, sending out three cars last week. It is the first ore shipped from the south belt of Rossland camp for eighteen months, says the Spokesman-Review.

Several Chinese companies are working the head of Wild Horse creek, near Fort Steele, East Kootenay district, some putting in wing dams. One will use the headrock flume near the mouth of Brewery creek. On Weaver creek T. Roberts has a shaft down 90 feet and is drifting to the rim; a water wheel has been put in to hoist gravel and water. At Perry creek Thompson & Co. are drifting on bedrock, two being run up the creek, carrying a

breast of 20 feet, and one down creek with a breast of 12 feet.

The official statistics of the Kettle River mining division for 1902 are: Free miners' certificates, 741; free miners' special, 4; locations, mineral, 324; locations, placer, 11; certificates of work, 807; abandonments, 6; certificates of improvements, 60; conveyances, 235; placer leases, 2.

Lessee B. C. Longley shipped a car of ore to the smelter last week from the Non Such claim near Boundary Falls. The Non Such is a group of four claims owned by the Republic M. Co., of Spokane. The Republic and Last Chance are opened by 100-foot shafts on the vein, and the Non Such by tunnels. The ore carries gold and silver.

The Lanyon Zinc Co. propose building a sampler and roasting plant at Kaslo.

The Le Roi No. 2 at Rossland earned profits of \$45,000 in December. The statement of shipments and profits for the Le Roi for the last eight months of 1902 is as follows:

Month.	Tons.	Profits.
May.....	13,047	\$ 66,932.53
June.....	11,475	72,640.24
July.....	14,492	92,898.42
August.....	17,009	71,270.53
September.....	13,667	61,091.49
October.....	15,204	84,232.49
November.....	15,576	76,482.63
December (estimated).....	13,500	45,000.00

Total..... \$570,548.33

The Phoenix Pioneer gives the following estimate of output of the province for 1902:

District.	Value.
Boundary.....	\$ 3,030,000
Rossland.....	4,381,000
Nelson.....	580,000
Slocan and Slocan lake, Lardeau and Trout lake.....	1,425,000
East Kootenay.....	250,000
Yale and Similkameen.....	100,000
Cariboo, Cassiar, Lillooet and Vancouver island.....	1,750,000

Total, metalliferous mines..... \$11,516,000
Coal and coke..... 6,500,000

Total..... \$18,016,000

JAPAN.

Manager K. Yamaguchi, the Furukawa Central mines, 70 miles from Tokio, says the company works in mines, smelters and offices 20,000 men. All are Japanese. Wages are 40 cents to 70 cents per diem, which is two or three times the amount paid for other classes of labor in Japan. They use, he says, machine drills for breaking ore, and electric engines on the horizontal workings. The deepest workings are down 1200 feet. They produce 1,500,000 pounds of copper monthly. The ore averages 4% copper with a small percentage of silver. It is concentrated to 15% copper and smelted by the company.

KLONDIKE.

The Munger quartz mill is in operation at Dawson, under the supervision of the government. Rock from W. Fester's claim, of the Dawson City group back of Dawson, was first crushed.

MEXICO.

CHIHUAHUA.

A 100-ton amalgamation plant and an aerial tramway are being installed on the Adela mine in the Azules (Santa Barbara district). Manager W. A. Petit says the ore runs 50 ounces silver and 1½ ounce gold.

COAHUILA.

The company of Texas men operating the Reforma mines in Madaquena mountain near Sabinas Hidalgo, will build a \$30,000 concentrating mill.

DURANGO.

The Guggenheim Exploration Co. is reported to have secured options on the Avino mines near Durango, for \$6,000,000.

GUANAJUATO.

Manager J. T. Judd, the Bolanitos mines, 8 miles from Guanajuato, says on the 120 level from the new shaft 5 feet of ore has been struck, which carries \$7 per ton gold and silver. The ore body has been followed for 50 feet. The Bolanitos is on the La Luz system of veins. Another shaft at a depth of 140 feet has an ore body 30 feet wide, which averages \$10 gold. The company propose to build a 250-ton cyanide mill. Some ore is being shipped. The deepest workings are 800 feet.

NUEVA LEON.

The Monterey News says Manager E. D. Self, the San Carlos mine, will resume operations at the smelter at San Carlos next month.

SONORA.

The El Tigre mine, southeast of Douglas, near the Pilares de Teras silver mines, were bonded recently to Philadelphia men

for \$500,000. The Sonora River Placer M. Co., in the same district, is putting in machinery. R. O. Munson, manager, says sluicing will begin Feb. 1.

The San Diego mine in Altar district is sold to T. W. Carter and the first payment of \$20,000 made.

TASMANIA.

From the Shepherd & Murphy mine concentrates containing wolfram, tin and bismuth have recently been treated magnetically to extract the wolfram. The treatment was reported successful.

A lode 4 feet 6 inches thick has been cut at the 200 level by the Volunteer Co. at Mathinna. The company had done considerable exploration work before it met with success.

PERSONAL.

B. JAMISON is superintendent Carlsbad mine, Tintic, Utah.

J. A. WALL, owning mines in Mariposa county, Cal., is in San Francisco, Cal.

W. J. NELSON, a mining man of San Andreas, Cal., is in San Francisco, Cal.

F. DAVIS AND L. W. TATUM of Chicago, Ill., are examining mines in Mexico.

C. E. WHITEFORD is superintendent Norwegian Con. M. Co., near Tuttle town, Cal.

J. HOBBS is superintendent the Red Rock mine at Big Bug, Yavapai county, Ariz.

W. H. WOOD has resigned as superintendent Colorado Co.'s mine at Butte, Mont.

P. A. DWYER is manager Hewitt mine, near Sandon, B. C., vice C. T. Cross, resigned.

W. R. WING of Oakland, Cal., has opened a general assaying office in Gold Hill, Or.

T. CLARK, superintendent River Hill mine, near Placerville, Cal., is in San Francisco, Cal.

T. H. FULLEN, superintendent Angels Quartz M. Co., Angels, Cal., is in San Francisco, Cal.

R. WHINNERAH, former manager Humphrey mill, Creede, Colo., is in Indianapolis, Ind.

W. W. EMMETT, of Wall Street, Colo., is superintendent the Freedmen mine, Central City, Colo.

H. W. TURNER, superintendent the Cherry Hill mine, Siskiyou Co., Cal., is in San Francisco, Cal.

PRESIDENT E. L. WHITE of the Bingham Con. M. Co., is at Bingham, Utah, from Boston, Mass.

W. BALL is superintendent of the Lower Mammoth at Tintic, Utah, under the new management.

E. R. ABADIE, superintendent Champion mine, Nevada City, Cal., is in San Francisco, Cal., this week.

J. CHIPMAN is president and manager Lower Mammoth M. Co., at Tintic, Utah, vice S. Bamberger, resigned.

C. E. STOEHR succeeds J. R. Christie as manager of the Bull-Domingo mine, near Silver Cliff, Custer Co., Colo.

W. L. WATTS of Los Angeles, Cal., has gone to Santa Barbara county, Cal., to investigate the new oil fields there.

F. B. CALHOUN, until recently chief amalgamator of the Alaska-Treadwell mine, Alaska, is in San Francisco, Cal.

C. E. KNOX, manager Montana-Tonopah M. Co.'s mines at Tonopah, Nev., returned last week from Philadelphia, Pa.

F. L. SIZER has accepted the position of consulting engineer to the Argo M. Co., 26 miles from Helena, Mont., shipping copper ore.

H. H. NICHOLSON, M. E., of Denver, Colo., has been looking over the Sumpter, Or., mining district in the interest of Eastern investors.

GEO. W. SNEIDER, E. M., a graduate of the Golden, Colo., School of Mines, has been appointed Deputy State Commissioner of Mines of Colorado.

D. A. LYON, formerly of the University of Washington, is at Stanford, Cal., to take up the work in metallurgy formerly conducted by Prof. Newsum.

BULKLEY WELLS, of Boston, Mass., has been appointed manager and O. B. Kemp superintendent of the Smuggler-Union mines at Telluride, Colo.

GEO. A. ANDERSON, general manager Gold & Silver Extraction Co., Denver,

Colo., is in Scotland on business connected with the company.

A. J. PIKE, millwright and assayer, is superintending construction of a mill at the Ellwilda mines on Whiskey creek, near Grant's Pass, Or.

WM. H. KRITZER, E. E., is in San Francisco, Cal., to assist in the electrical and gas engine department of the Joshua Hendy Machine Works.

D. R. WILLIAMS has resigned as superintendent the Carisa mine, Tintic, Utah, to accept the superintendency of the McCabe mine near Prescott, Ariz.

E. C. LIMBACH of Denver, Colo., has returned from Chihuahua, Mexico, to take a position with a mining company at Maiden, Mont., to do cyanide work.

C. W. MERRILL, who has been at Lead City, South Dakota, for the past three years in charge of construction and operation of the large cyanide plants of the Homestake Co., is in San Francisco, Cal.

J. F. NEWSOM, associate professor of mining and metallurgy at Stanford University, Palo Alto, Cal., has returned from a tour of Europe, where he has been investigating the principal mining schools.

Commercial Paragraphs.

THE meeting of the board of directors of the Allis-Chalmers Co., held Jan. 15, declared regular quarterly dividend on preferred stock.

FAIRBANKS, MORSE & Co., Denver, Colo., has orders for two 60 H. P. gasoline engines for B. F. Morley, Buena Vista, Colo., two 34 H. P. compressor plants for Idaho Springs, Colo.

THE Gutta Percha & Rubber Mfg. Co. of San Francisco, Cal., report a pressure of orders for their lines, "Spadone" concentrator belts, hose, belting, etc., that requires their utmost exertions to meet.

MESSRS. BETHUNE & TRUAX, assayers and analytical chemists of Los Angeles, Cal., have removed their offices to 115 1/2 N. Main street, where they have opened a school of assaying, Mr. Bethune being a teacher in that line.

PAWLING & HARNISCHFEGGER, Milwaukee, Wis., makers of electric cranes and hoists, advise that "condition of business during 1902 was better than during any other year since they started business in 1884. Their crane orders for 1902 averaged at the rate of one for each working day, or 300 in all." Among the representative companies that are purchasers of cranes made by Pawling & Harnischfeger are the following, to which names are added the number of cranes purchased: Allis-Chalmers Co., 71; The Midvale Steel Co., 43; American Bridge Co., 30; Baldwin Locomotive Interests, 30; New York Shipbuilding Co., 16; United States Government, 10; Pennsylvania Railroad Co., 8; Bethlehem Steel Co., 7.

Catalogues Received.

Bound in red and bound to be read is the latest catalogue (No. 12) of the Joshua Hendy Machine Works of San Francisco, Cal., which treats on mining and milling machinery for operating and developing gold mines. The illustrations would do credit to a first-class magazine, and the description of the different devices is clear and concise.

The Mine & Smelter Supply Co. of Denver, Colo., have issued catalogue No. 16. It is descriptive of mining machinery of such description as almost every mine requires and includes several types of hoists, station and sinking pumps, compressors, boilers, water heaters and engines, skips, cages, cars and drilling machinery, as well as a variety of tools. It gives sizes and weights and much valuable information concerning the various devices illustrated in the book.

Books Received.

"Production and Properties of Zinc," is the title of a new work on this subject, by Walter R. Ingalls. It is a carefully written and illustrated treatise on the occurrence and distribution of zinc ore, the technical and commercial conditions affecting the production of spelter, its chemical and physical properties and uses in the arts. It presents a comprehensive view of the world's resources of zinc ores,

as far as known; 328 pages, 66 figures; \$3 net. The Engineering and Mining Journal, New York City.

Obituary.

D. B. LYMAN, a well-known mining man and former superintendent Con. Virginia mine on the Comstock, Virginia City, Nev., died at Reno, Nev., on the 16th inst., of pneumonia. He was a native of Vermont, aged 67.

New Patents.

DEWEY, STRONG & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR THE WEEK ENDING JANUARY 13, 1903.

- 718,300.—RULE—M. G. Bailey, San Jose, Cal.
718,361.—DENTAL ENGINE—C. R. Basford, S. F.
718,375.—KILN—C. S. Batchelder, Spokane, Wash.
718,418.—GARMENT SUPPORTER—B'com & Menor, Seattle, Wash.
718,308.—FRUIT PACKING APPARATUS—Braun & Scott, Cupertino, Cal.
718,319.—CREAM SEPARATOR—J. G. Cunningham, Bellavista, Cal.
718,108.—MANIFOLD BOOK—G. B. Doyle, Berkeley, Cal.
718,454.—BURGLAR ALARM—Handy & Hosford, S. F.
718,280.—BAKE OVEN—P. E. Laskowski, Los Angeles, Cal.
718,264.—TELEPHONE MOUTHPIECE—J. F. Logue, Sacramento, Cal.
718,364.—SWITCH—J. P. Lowe, Seattle, Wash.
718,505.—TYPE WRITER—P. F. Nilson, Jerome, Ariz.
718,276.—DREDGER—R. A. Perry, Oakland, Cal.
718,278.—GARMENT SUPPORTER—E. L. Pitts, Jerome, Ariz.
718,525.—MARINE BOILER—A. E. Roberts, S. F.
718,164.—SCAFFOLD—M. S. Smith, Tacoma, Wash.
718,167.—MERCURY TEST GAUGE—Spencer & Fisher, S. F.
718,290.—GAME BOARD—N. B. Stone, Outlook, Wash.
718,232.—WOOL SCOURER—F. L. Whitney, S. F.
718,233.—RAILWAY SIGNAL—J. W. Williams, Spokane, Wash.
718,460.—FLUSHING TANK—W. A. Williams, S. F.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

DREDGES.—No. 718,276, Jan. 13, 1903. R. A. Perry, Oakland, Cal. The object of this invention is to construct the dredging apparatus, and especially the supporting ladder, that it may be attached to the hull of an ordinary vessel without material change therein, said apparatus projecting so far from the front of the vessel that it can cut a channel through which the vessel may float. The main engines of the vessel may have the shaft provided with couplings and located in line between a propeller shaft and the shaft of the suction pump, so that by disconnecting one set of couplings and connecting the other the suction apparatus may be operated when it is desired to move the vessel from place to place. In conjunction with these devices I have shown a crane and mechanism by which the ladder and dredging mechanism may be lifted and sustained in such position as not to interfere with the movements of the vessel when traveling. This invention reduces the cost and also simplifies construction as hitherto used in dredgers.

ATTACHMENT FOR TELEPHONE MOUTHPIECE.—No. 718,264, Jan. 13, 1903. J. F. Logue, Sacramento, Cal. The object of this invention is to provide a simple means of preventing the transmission of disease germs through the medium of the usually unprotected mouthpiece. It consists in the combination with a telephone mouthpiece of a wire frame secured thereto and said frame comprising a single piece of wire centrally bent to form a loop embracing the mouthpiece, but out of contact therewith and approximately in the same plane with the open end of the mouthpiece and the portions of said wire intermediate of said loop and its point of connection with the mouthpiece bent to form a support for a sheet of paper.

FRUIT PACKING APPARATUS.—No. 718,308, Jan. 13, 1903. C. A. Braun and W. M. Scott, Cupertino, Cal. This invention is designed to provide a simple means for packing and pressing dried prunes, figs, raisins and other fruits uniformly and expeditiously into small packages or cartons preparatory for shipment. It consists in the combination in a packing apparatus of a supporting frame, forms thereon, holders fitting said forms and adapted to have a sheet forced thereover, a shield fitting over the end of said holder and protecting the sheet, said shield open along one side, plungers by which the fruit may be compressed in the holders, and clamps upon said frame in which a package may be held after the holder is withdrawn and while the open end of the sheet is being folded.

CREAM AND BUTTER SEPARATOR.—No. 718,319, Jan. 13, 1903. J. G. Cunningham, Bellavista, Cal. This invention consists of a support or base including a bracket having a tubular portion provided at its upper end with a stuffing box, and having a shoulder 14. A receptacle is provided having a central opening in its bottom and having a sleeve 6 and an annular flange adapted to rest upon said shoulder, with means for detachably coupling the said sleeve to the bracket, and a vertical shaft extending through the tubular portion of the bracket, and having, at its upper end, an enlarged head adapted to rest upon the top of the said tubular portion. A vertical hollow stem open at both ends is provided with flanges on the lower part of the stem and radial blades fixed between said flanges, said stem having perforations between said blades, means for rotating the shaft, and vertically disposed, perforated baffles on the stem and also fixed to the receptacle.

Latest Market Reports.

SAN FRANCISCO, Jan. 23, 1903.

METALS.

SILVER.—Per oz., Troy: London, 21 3/4 (standard ounce, 925 fine); New York, bar silver, 47 1/2; refined (1000 fine): San Francisco, 47 1/2; Mexican dollars, 38 @ 39c San Francisco, 37 1/2 New York.

COPPER.—New York: Standard, \$11.62; Lake, 1 to 3 casks, \$12.15; carload lots, \$12.00; Electrolytic, 1 to 3 casks, \$12.05; carload lots, \$12.25; Casting, 1 to 3 casks, \$12.00; carload lots, \$11.10. San Francisco: \$14.00. Mill copper plates, \$17.00; bars, 18 @ 24c. London: £52 13s 9d spot per ton.

LEAD.—New York, \$4.12; Salt Lake City, \$3.50; St. Louis, \$4.00; San Francisco \$4.50, carload lots; 4 1/2 1000 to 4000 lbs.; pipe 5 1/2, sheet 6, bar 5 1/2; pig, \$4.75. London: £11 11s 3d per ton.

SPELTER.—New York, \$4.05; St. Louis, \$4.50; London, £20 6s 6d per ton; San Francisco, ton lots, 6 1/2; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9 1/2; Hallett's, 8 1/2; San Francisco, 1000-lb. lots, 10c; 300 to 500 lbs., 11c; 100-lb. lots, 13 @ 15c.

TIN.—New York, pig, \$28.00 @ 28.25; San Francisco, ton lots, 30c; 500 lbs., 30c; 200 lbs., 30 1/2; less, 31c; bar tin, 3 1/2, 35c. London, £128 5s spot.

PLATINUM.—San Francisco, crude, \$18.00 @ 19 oz.; New York, ingot, \$19.00 per Troy oz. Platinum ware, 75 @ 80c per gram.

QUICKSILVER.—New York, \$45.50 @ 46.50; large lots; London, £8 15s; San Francisco, local, \$45 50 @ flask of 7 1/2 lbs.: Denver, \$49.50. Export, \$43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6 1/2c; extra, 17 1/2c; genuine, 35c; Eclipse, 37 1/2c.

ALUMINUM.—New York, No. 1, 99 1/2 pure ingots, 35c; No. 2, 90 1/2, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 19 1/2c; San Francisco, Plumbers', 100-lb. lots, 16 1/2c.

NICKEL.—New York, 50 @ 60c @ 7c; ton lots, 45 @ 48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$22.00; gray forge, \$20.15; San Francisco, bar, 3c @ 4c, 3 1/2c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$28.00 @ 30.00; open hearth billets, \$30.50 @ 34.00; San Francisco, bar, 7c to 12c per lb.

CHICAGO CURRENT QUOTATIONS.

Special rates for carload lots.

GENERAL SUPPLIES.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15 1/2c; less than one ton, 17 1/2c. No. 1*, 60%, carload lots, 13 1/2c; less than one ton, 15 1/2c. No. 1** 50%, carload lots, 11 1/2c; less than one ton, 13 1/2c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2*, 35%, carload lots, 9 1/2c; less than one ton, 11 1/2c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 725 kegs, \$1.50 per keg; less car lots, \$2 per keg.

CAPS.—3x, \$5.50 per 1000; 4x, \$6.50; 5x, \$8; Lion, \$9, in lots not less than 1000.

FUSE.—Triple tape, \$3.60 per 1000 feet; double tape, \$3.00; single tape, \$2.65; Hemp, \$2.10; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10 1/2c @ set; 14 oz., 40s., 9 1/2c.

CHEMICALS.—Cyanide of potassium, 98%—99%, jobbing, 25 @ 26c @ 3c; carloads, 24 @ 24 1/2c; in 10-lb. tins, 35c; sulphuric acid, in carboys, 66 1/2 B, 2c @ 3c; soda ash, \$2.00 @ 100 lbs.; hyposulphite of soda, 2 1/2 @ 3c @ 3c; blue vitriol, 5 1/2 @ 6 1/2c @ 3c; borax, concentrated, 7 @ 8c @ 3c; chloride of potash, 12 @ 13c; roll sulphur, 4 @ 6c; ground sulphur, 4 @ 6c; flour sulphur, French, 2 @ 3c; alum, \$2.00 @ 2.25; California refined, 2 @ 2 1/2c; nitric acid, in carboys, 8c @ 9c; caustic soda, in drums, 3 @ 4c @ 3c; Cal. s. soda, bbls., \$1.25 @ 1.50 @ 100 lbs.; sds, \$1.05; chloride of lime, spot, \$3.00 @ 4.00; nitrate of potash, in bbls, 8c; caustic potash, 10c in 40-lb tins; sulphide of iron, 9c @ 3c; copper sulphate, 5 @ 7c.

CEMENT.—Germania, \$2.50 @ 2.75; K. & B. S., \$3.00; Hewmoor, \$2.90; Trowell, \$2.90; Portland, \$2.50 @ 2.75 per bbl.

OILS.—Linsed, boiled, bbl, 56c; cs., 61c; raw, bbl, 54c; cs., 59c; lots of 5 bbls, 1c less; Lucol oil, boiled, bbl, 50c; cs., 55c; raw, bbl, 48c; cs., 53c. Kerosene—Pearl, per gal., 22c; Astral, 22 1/2c; Star, 22 1/2c; Extra Star, 25 1/2c; Eocene, 24 1/2c; Elaine, 27 1/2c; Water White, in bulk, 16c; Mineral Seal, iron bbls, 18 1/2c; wooden bbls, 21c; cs, 24c; Mineral Sperm, cs, 26 1/2c; Deodorized Stove Gasoline, bulk, 18 1/2c; do., cs., 25c; 8 1/2 Gasoline, bulk, 21c; do., cs., 27 1/2c; 6 3/4 Naphtha or Benzine, deodorized, in bulk, per gal., 16c; do., in cs., 22 1/2c; Lard Oil, No. 1 bbl, 95c; cs., \$1.00; Neatsfoot oil, bbl, 70c; cs., 75c; No. 1 bbl, 55 @ 57 1/2c; cs., 57 1/2 @ 60c; Sperm, crude, 50 @ 60c; Natural White, 65c; Bleached do, 70c; Whale Oil, cs, 50 @ 55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6c; 1 ton and less than 5 tons, per lb., 6 1/2c; 500 lbs. and less than 1 ton, per lb., 6c; less than 500 lbs., per lb., 6 1/2c; in 25-lb. tin pails, 4c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, 4c per lb. above keg price. Dry Lead—in bbls, 1 ton and over, 6c; do. in kegs, 6 1/2c.

RED LEAD.—One ton and over at one purchase, per lb., 6c; 500 lbs. and less than 1 ton, per lb., 6 1/2c; less than 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8 @ 9c per lb.

BONE ASH.—Extra No. 1, 5 @ 6c per lb. No. 1, 4 @ 5c.

BORAX.—Concentrated, 7 @ 9c per lb.; powdered, 9 @ 12c; fused, 25 @ 30c.

BISMUTH.—Subnitrate, per lb., \$1.60.

BONE ASH.—4c @ 7c.

BORAX.—Crystal, 7c; calcined, 25c.

COPPER.—Sulphate, 5 @ 7c.

MANGANESE.—(90% and over) 3 @ 4c, \$1.25.

MERCURY.—Bichloride, 3 @ 4c, 90c.

PHOSPHORUS.—(American) 3 @ 4c, \$1.00.

SILVER.—Chloride, 3 @ 4c, 75c; nitrate, 55c.

SODIUM.—Metal, 3 @ 4c, \$1.25.

URANIUM.—Oxide, 3 @ 4c, \$3.50.

ZINC.—Metallic, chemically pure, 3 @ 4c, 50c; dust, 3 @ 4c, 10c; sulphate, 3 @ 4c, .04c.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

HAVE THE CALIFORNIA DEBRIS COMMISSION having received applications to mine by hydraulic process from Andrew Cusledge in Forty Nine Pacer Mine, near Mountain Ranch, Calaveras County, Cal., draining into McKinney Creek which reaches Calaveras River; from Frank Vere in Elm Pacer Mine, near Quincy, Plumas County, Cal., draining into Taylor Creek which reaches Feather River; from Nelson Contracting Co. in Calaveritas Hill Mine, near Calaveritas Hill, Calaveras County, Cal., draining into Oneil Creek which reaches Calaveras River, gives notice that a meeting will be held at Room 96, Flood Building, San Francisco, Cal., Feb. 9, 1903, at 1:30 P. M.

Hydro-Carbon Smelter, Mayer, Arizona.

Front View Hydro-Carbon Smelter, Mayer, Arizona.

A Hydro-Carbon Smelter.

At Mayer, Yavapai county, Arizona, a furnace of unusual construction has been built to smelt copper ores by a process employing crude petroleum as fuel. The ore is crushed to nut size, no piece larger than will pass a $\frac{3}{4}$ -inch ring. This passes down what may be termed the inclined hearth of the furnace, constructed at an angle of about 45° , at the foot of which is a horizontal hearth or floor. Upon this the

ore falls and extending upward on the inclined hearth is subjected to the powerful heat of the petroleum blast, the ore matting at and near the lower hearth, melting and flowing over into a lower compartment, the slag being tapped at one opening, and the matte at a lower one. The illustrations show a general view of the smelter buildings and surroundings, and of the front of the furnace from a nearer point.

The process is undergoing some changes, sug-

gested by experience, as is the case with most new processes. One important change suggested by M. P. Boss, the inventor of the process and furnace, is that of crushing the ore much finer, by which means it is expected more satisfactory results will be obtainable. The experimental runs have been made through the short period of two months under many disadvantages. When a constant supply of ore is available still more favorable results are anticipated in the application of this novel process.

AN index of what the cyanide process is doing for the development and operation of Black Hills, South Dakota, mines is found in the fact that 70-cent tailings are being treated direct from some of the mills of the Homestake Co. at a good profit. It is expected that a still further reduction in cost of treatment will be made.

THE recent purchase of the branch railroad from Goff's station, in eastern San Bernardino county, Cal., northward to Manvel, by the Santa Fe Co., and the fact that a corps of railroad engineers are afield in southern Nevada is a matter of interest to miners in that section. The extension of this road northeasterly, whether making connection with Salt Lake or not, will be of great benefit to the mines within reasonable distance of the line. The transportation problem is one of the most important that the miner has to struggle with in desert regions, and a railroad always renders great assistance in this regard. Distance in the desert regions of the southwest is not considered by the same standard as in sections more fortunately situated. There 30 to 60 miles, or as far as one can drive in twenty-four hours, is not looked upon as prohibitory, though the miner at the same time realizes the benefit of having a railroad nearer than at a greater distance. The extension of this road, to be known as the California and Eastern, would not fail to benefit the mines located 30 to 50 miles either side of the line, as fuel, supplies and timber, etc., could be delivered at greatly reduced cost, and much of the ore could be hauled elsewhere for treatment. Fortunately much of the ore of those regions is high grade and can stand the charges for transportation by railroad, when they would otherwise remain idle. The region along the proposed route abounds in ores of many varieties, and while these are generally high in grade, there are also large amounts of ore too low in grade to ever be worked without such benefits and opportunities as a railroad would afford.

The Secondary Enrichment of Ore Deposits.

Of late a great deal has been said and written concerning the secondary enrichment of ore bodies. Some of the theories advanced and conclusions reached are instructive, and some of them amusing. That such a condition as "secondary enrichment" under certain conditions does actually occur is indisputable, but this phenomenon is much more restricted in its occurrence than some writers on the subject seem to believe.

Many mineral veins, particularly those bearing lead and silver, or copper ores, are found much impoverished in their upper portions, though an increase in values in depth is noticeable, but in most instances these values are normal, and represent the values originally deposited, and are not, as a matter of fact, in a zone of secondary enrichment at all. In many copper-bearing veins and deposits, the metal is leached from the upper or superficial portions of the mass, iron oxides, silica and lime usually constituting the gossan. In exploring such deposits as depth is attained the carbonates and oxides of copper sometimes appear, and often form large and valuable ore deposits. Passing downward through these, the ore, either gradually or suddenly, turns to the normal sulphide, and as greater and greater depth is attained the average copper content of the rock grows less and less. The relatively rich upper portion (beneath the gossan) may be called a primary enrichment due to oxidation of sulphides, and to subsequent concentration by redeposition in the zone referred to, this resulting from the downward flow of waters, but the further or secondary enrichment in a zone intermediate between the zone of carbonates and oxides, and the normal sulphide zone below, in which are found chalcocite and numerous other more complex sulphide ores, rich in copper, and sometimes in gold and silver as well, is of relatively rare occurrence. This condition is pronounced in the mines of Butte, Montana, and has no counterpart on so great a scale elsewhere, though to a limited extent a somewhat similar phenomenon has been observed in other copper mines, notably in Arizona.

Secondary enrichment of the character indicated seems probable only in veins and deposits containing large amounts of sulphide ore, and in only rare instances is it likely to be found in veins and deposits not essentially of this character.

Highly siliceous gold or silver-bearing ores are not, apparently, subject to this sort of alteration. In the gold mines of California, representing a wide range of veins of this latter class, no such condition as secondary enrichment has been reported, if observed, unless the occasional occurrence of bunches or pockets of gold in some of these veins be considered as representative of this kind of deposit. The fact that these unusually rich shoots occur at greatly varying depth, from the surface down to 2500 feet and deeper, having no connection with each other, and that their existence has not, apparently, had any influence upon the vein in its vicinity, either to enrich or impoverish it, does not tend to strengthen the belief in a zone "of secondary enrichment" in veins of this class.

In some gold-bearing veins a reverse condition is found, that is, the ores at and near the surface are found to be richer than the ores developed in depth, and this, too, where the values are so evenly distributed as to preclude the supposition or probability that the superficial portion was originally richer. This condition is sometimes observed in veins much "honeycombed" and oxidized by meteoric agencies, and is particularly noticeable in the desert regions of the Southwest. The enrichment is probably due to the removal of certain soluble portions of the original gangue material, and the oxidation of the sulphides. A given bulk of this ore will weigh less than the normal ore, while containing the same quantity of gold, and in some instances, doubtless, there is an enrichment due to dissolution and redeposit of gold, at a lower point in the vein; but this may properly be called a primary and not a secondary enrichment of the vein. It is, no doubt, a matter of satisfaction, when working a payable mine, for the owner to contemplate increased returns when the greater depth in the zone of secondary enrichment is reached, while the miner who is working a property that fails to

pay expenses may console himself with the reflection that he will soon reach this elusive zone. But these are mostly fallacies, and the history of mining, with a few exceptions—valuable or interesting only mineralogically—proves that there is no good reason for such hallucinations.

That sulphide copper ores deteriorate in value with great depth (below 1500 feet) seems established by experience in mines of this character wherever worked to this depth or deeper, but that the same may be said of gold mines is not shown to be true, for the deepest paying vein gold mines in the world have rich and poor spots at all depths from the surface down to 3000 feet, and deeper, there being no uniformity in the amount of gold contained in the rock, while, on the other hand, the expense constantly increases with greater depth.

The Value of Managers' Reports.

The value of the periodical report of a mine manager or superintendent lies chiefly in the details of cost given. A report comprising tabulated statements, no matter how elaborate or to what extent the printer's art may have been employed, is of no practical value unless it deals with facts—all the facts—and makes it possible for others who know nothing of the conditions under which the costs were made, to gain a comprehensive idea of what has been accomplished, and by comparison to obtain valuable information. The annual reports of some mine managers contain nothing but general statements, though the reports in themselves are voluminous and, to the casual reader, apparently all that could be desired. These reports state the amount of receipts and disbursements, but no details are given, and one searching them for the purpose of getting the cost of doing certain work, or the cost of producing whatever the product may be, will find nothing upon which to base calculations. Then there are those who give the cost of certain things and omit others of equal importance. These reports on their face usually make a good showing for the superintendent or manager, but when carefully looked into it is found that important items and costs have been inadvertently or intentionally omitted.

When driving drifts and crosscuts, the cost sheet is incomplete unless it shows the cost of drilling, cost of power, if machines are used; cost of repairs of machines; cost of supplies; ventilation, timber and timbering; hoisting from that level; track laying, repairs, and, in fact, every item of expense that is incident to the opening, equipment and maintenance of the level. The amount of water taken from the level is also a charge against it, whether it be drawn in skips from a tank on the level, pumped to the surface or allowed to run down the shaft to be bailed from the bottom. Its proportional share of superintendence must also be included. Carefully prepared cost sheets giving these details often show a marked difference in cost per foot on various levels in the same mine. Investigation usually shows this to be due to a change in the character of the ground; the amount of timber necessary; quantity of water handled, or other causes.

In shaft sinking the factors influencing cost are as numerous as those in driving levels. The hardness of the ground; efficiency of machines, if used, and capabilities of the men (in either case); means for handling water, if troublesome; timbering, and size of the shaft—all are important. The charge for handling men, and timbers, and other materials cannot be omitted, and cost of hoisting is important. The latter constantly increases with depth, when all other conditions remain the same.

Unless all of these items are included in the statement, the report loses much of its value.

AN unusual condition at present obtaining on the Pacific coast is evidenced in the fact that large amounts of railroad rails and structural steel is being brought into California by vessel from Germany, the saving said to amount to from \$5 to \$7 per ton. These vessels after discharging their cargoes of steel take grain on the return trip to Europe. Securing full cargoes both ways has resulted in making it possible for German iron and steel manufacturers to successfully compete with those of the United States.

CONCENTRATES.

GOLD melts at 1240° Centigrade, and is slightly volatile.

THERE is no duty upon copper ore imported into the United States.

SERPENTINE is a hydrous, and talc an anhydrous, silicate of magnesium.

ASSESSMENT WORK done in any one year in excess of the requirement of the law can not be applied on the following year's assessment.

IN Overman's "Treatise on Metallurgy," published in 1852, will be found a description of the water-jacketed blast furnace in use at that time.

THE London lead quotation in this week's issue—£11 8s 9d—is per long ton (2240 pounds), and with United States exchange at \$4 8666 is equivalent to 2.49c per pound. The duty of 2½c is independent.

TO CALL "graphitic schist" occurring in an area of old crystalline schists "bituminous schist," simply because one believes that it may at one time have been a bituminous shale or sand rock, is not good nomenclature.

FREIGHT RATES on ore from Acapulco, Mexico, to San Francisco, Cal., vary according to values. On ore not exceeding \$100 gold per ton \$4 25 is charged; between \$100 and \$200, \$5; \$200 and \$500, \$7.50; \$500 to \$1000, \$10.

THERE is no remedy for headache caused by powder smoke (nitrous oxide), though there are several preparations which are represented to give relief. Sleep is the best remedy and the most effectual. Good ventilation in the mine is a preventive.

BRITTLE COPPER when heated to redness becomes soft and is said to be "annealed," whether cooled quickly or slowly. Commercial copper usually contains small amounts of silver, arsenic, bismuth, iron and other metals, but is pure enough for most practical purposes.

PURE potassium cyanide is made by passing the vapor of hydrocyanic gas into an alcoholic solution of potassium hydroxide, when the salt separates in small crystals. The potassium cyanide of commerce is made by melting dry potassium ferrocyanide. Mixing potassium carbonate with the charge increases the yield of potassium cyanide, but the product is said to be inferior in quality.

A ½-INCH steel rope of nineteen wires will give a factor for safety of six times the weight, or tension, on a tramway 1400 feet long, having 44% grade, with a car weighing 1000 pounds and carrying a load of 2000 pounds. This rope may be wound on a 3-foot diameter reel without injury, and the cars can be controlled with a band brake. The maximum tension loaded is 3412 pounds and empty 1348 pounds.

THE cheapest power is free water power, provided the necessary expense for making it available does not cost too large a sum. There are instances where the interest at usual rates on the money invested in dams, flumes, ditches, etc., and the cost of repairs in maintaining the water privilege, makes it more expensive than steam or electric power. This permits independence, but does not look like good business.

IN reply to questions concerning the issue of "Mineral Resources of the United States, 1901," the report for 1901 will appear as a distinct publication. As heretofore, it will contain a statement of the production of every mineral in the United States, with its value, where it is mined, etc. Application for the report should be made to members of Congress, who will have a limited number for distribution.

STEEL "T" RAIL weighing twelve pounds to the yard is sufficiently heavy to carry mine cars holding one ton of ore, if the ties are 6 inches wide and placed 30 inches from center to center. If the number of cars run over the line be large, or if they are run in trains of several cars each, a 16-pound rail is advisable. Underground, however, where cars usually carry but 1600 to 1800 pounds, and are trammed by men, 12-pound rail is recommended, as easier to handle at the shaft, and they can be bent at turns with ease.

PERIDOTITE is a dark basic rock similar to gabbro, but without feldspars, and with predominant olivine. Owing to the variations in the olivine the rocks of this group, though essentially similar, have various names. One variety—picrite—is a compound of olivine and augite. It is mainly olivine, and the rest a compound of augite, hornblende and magnetite; blackish green, and almost compact with olivine. It is the predominant rock at the diamond mines of Kimberley in South Africa, and has on this account unusual interest.

THE process of electro-plating metallic surfaces with silver is accomplished by placing the article to be plated

in a solution of silver cyanide in potassium cyanide, and connected with the negative pole of a battery, the positive pole of which is joined to a sheet of pure silver, also suspended in the solution. The electric current decomposes the silver cyanide, and the silver is deposited on the suspended article in a firm coating. At the same time silver goes into solution from the silver sheet suspended in the bath, thus keeping up the strength of the solution.

EFFECTIVE results cannot be obtained with a nozzle of any size when the pipe line is full only half way to the pressure tank, nor is the fullest efficiency obtainable when the pipe at the pressure box is not entirely covered by water, as otherwise air passes down the pipe line with the water destroying the fullest effect of the stream when delivered at the wheel. The greatest efficiency is obtained when the largest possible nozzle is employed, which still permits the pressure tank to remain full of water, but without overflowing. The efficiency is further increased if the water is 2 or 3 feet at least above the top of the intake pipe.

DIORITE may be described as a wholly crystalline, coarse and fine-grained rock composed of lime-soda, feldspars and hornblende, with mica and pyroxene, sometimes porphyritic. Its color is influenced largely by the texture of the rock and the amount of hornblende and pyroxene present. In color it ranges from light gray to dark green and black, though the black varieties always are found to be green in thin sections. When sheared, compressed and altered it becomes amphibolite schist. It may contain quartz in grains, and is then called quartz-diorite. Many valuable gold and silver veins are found in diorite.

CAREFUL chemical examination of the ore sent from Lake City, Colo., failed to show the presence of platinum. This metal has been found in numerous localities in placers, but in only a few localities in rock in place, notably in the Ural mountains in eastern Russia. Whenever observed in rock it has been found in dark basic rocks like serpentine and peridotite, and not as yet in diorite or other igneous or sedimentary rocks. Diorite is specifically mentioned as the country rock sent with the ore, appears to have been diorite, now much altered. It contains marcasite (white iron sulphide) and the ore consists of a mixture of fine grained galena, zinc blende, iron sulphide and a little copper sulphide. It may also contain gold and silver. No determination for these metals was made.

THE usual cause of particles of hard amalgam being found on the concentrating tables, and in the tailings, may be assigned to a careless mill man. Sometimes it may be directly due to a marked variation in value of the ore, but the mill foreman or head amalgamator is there to look out for such occurrences. A mercury trap will assist in catching hard amalgam scoured from the plates on "loaded quick" which runs off in globules. A suitable trap for a 5-stamp battery is similar to those in use in the Homestake mills, South Dakota. The dimensions are 8 inches wide by 10 inches long, 18 inches high at one end and but 6 inches at the other, with three sheet iron partitions, arranged like those in zinc precipitation boxes in cyanide works, the pulp passing alternately over one partition and under the next. This has a tendency to quiet the flow of the material, giving the quicksilver and gold an opportunity to settle.

IN the location of mining claims the proper direction of end lines is of greater importance than that of the side lines. The end lines must be parallel or the locator loses his "extralateral right." The side lines need not be parallel, however. Often in new mining districts, before the vein system is well understood, locations are made in many directions and numerous conflicting claims result. Many irregularly shaped pieces of ground remain when claims are taken thus indiscriminately, and these are also subject to location, provided the locator can find the apex of a portion of a vein in the tract. Often these pieces of ground form but a small fractional part of a full claim, but the locator must see that, having found the apex of a vein thereon, he makes his end lines crossing the lode line parallel to each other, regardless of the irregular outline of the balance of the claim, even if he is obliged to cut out a portion of the unclaimed ground to comply with the law, otherwise, as above stated, the locator is not entitled to follow his vein beyond a plane drawn downward vertically through his boundaries. When a junior locator, inadvertently or otherwise, so places his stakes as to include a portion of a prior location he can only get title to that part of his claim defined by the lines of the prior locator, but again, in the event of this resulting in non-parallelism of his end lines, he is debarred from the enjoyment of the extralateral right. In a circular of the land department issued October 25, 1895, the Commissioner of the General Land Office sanctioned the right of a junior to extend one-half of his end line within the surface lines of a prior location for the purpose of paralleling the end lines, but "Lindley on Mines" thinks this is based on an erroneous construction of the law.

MOST of the States and Territories subject to congressional mining laws have enacted statutes providing for proof, in the form of affidavits establishing the fact that the annual labor for a given year has been performed. This class of legislation is found in California, Colorado,

Idaho, Montana, New Mexico, Utah, Wyoming, Arizona and Nevada. The failure to comply with the law by filing such affidavit is accompanied by no serious penalty. There is no provision in any of the State or Territorial statutes to the effect that a failure to comply with its terms will work a forfeiture. A forfeiture of a mining claim can not be established, except upon clear and convincing proof of the failure of the locators or owners of the claim to have work done or improvements made to the amount required by law. For the purpose of curing defects in location, or readjusting boundaries, an original locator may relocate a claim. This is called an "amended location." Where the original locator seeks to evade the requirements of the law as to development work, or annual assessment, and endeavors to hold his claim by a new location of the same ground, such right has been recognized by the Circuit Court and by the Land Department; but this must be done before entry by another. While certain State courts have decided that an original locator may relocate a claim upon which the annual assessment work has not been performed, and repeatedly do the same periodically, "Lindley on Mines" says that this would defeat the purpose of the law and is a fraud upon the Government, and intimates such practice would not stand the test of the Supreme Court of the United States. It is not necessary to file a notice of relinquishment; but, if it is desired to hold a forfeited claim, the original locator may do so, if not already claimed by another, by commencing at once to do the neglected assessment work and continuing it to completion.

THE States and Territories may make laws regulating the location of mining claims, annual labor, etc., but these can in no manner conflict with the laws of the United States. In Arizona the Act of 1895, Section 3, says: "Before filing location certificate with the recorder of the proper county the discoverer shall locate his claim by: First, sinking a discovery shaft upon the premises, so claimed, to the depth of at least 10 feet from the lowest part of the rim of such shaft at the surface, and deeper, if necessary, until there is shown by such work a lode deposit or mineral in place; second, by posting at the point of discovery, on the surface, a plain sign or notice substantially conforming to the location certificate; third, by marking such claim or premises on the ground so that its boundaries can be readily traced." Section 5 of the same Act reads: "Any open cut, cross-cut, adit or tunnel, which shall be made as above provided for, as a part of the location of a mining claim, and which shall be equal in amount of work to a shaft 10 feet deep, and 4 feet wide and 6 feet long, and which shall cut a lode or mineral in place at the depth of 10 feet from the surface, shall be equivalent as discovery work, to a shaft sunk from the surface." The law of 1901 is similar to that of 1895, but requires for a valid location that the locator shall within ninety days from date of location, monument his claim, perform the work above described, and record the location with the county recorder. It may be further stated in the case of Arizona, that although the law does not specifically say so, eminent legal authority is of the opinion that the work required by the Territorial law is a portion of the act of location and may not be considered as "annual assessment work" required by the Federal law, as this latter must be performed in addition to the "location work." The Federal law permits States and Territories by legislation to increase the amount of work required on a mining location, but they cannot make the amount of annual assessment less than \$100.

THE early experiments on the cyanide process were made at the Calumet mill, Shasta county, Cal., then under the management of Almarin B. Paul, who went to Denver, Colo., for the purpose of investigating the process, and who was the first to introduce it on the Pacific coast. THE MINING AND SCIENTIFIC PRESS was the first to give full data as to these first workings. These can be seen by referring to papers of the following dates: March 5, 1892; April 9, 1892; June 4, 1892; July 2, 1892, and January 26, 1893. In Mr. Paul's letter of June 4, 1892, occurs the following respecting a weak solution of cyanide: "The McArthur-Forrest process is the use of a weak solution of cyanide of potassium. The strength of cyanide being as your ore may show is required." Mr. Paul's first workings on a practical scale of ten tons per charge was more successful than were the Denver workings, and so surprised were they that they sent out one of their company to investigate, and who stayed at Calumet for a week, Paul's extraction at times running as high as 95%, but usually from 85% to 90%. The first workings were with 1% solution, then Mr. Paul commenced experiments on a reduction, the first being three-fourths of 1%. This giving as good a percentage of extraction, he then used one-half of 1%, and so on down to one-sixth of 1%. These experiments caused Paul to adopt one-fifth of 1% as producing as good results as a higher percentage; these experiments all being made on the same ore were conclusive. Mr. Paul was also the first to use a weak solution of cyanide in the battery, as the following lines show in his letter published in the MINING AND SCIENTIFIC PRESS and bearing date January 7, 1893, as follows: "As to the matter of wet or dry reduction of ores, I am decidedly in favor of the wet, using the solution in the battery, and more especially, as I see what can be accomplished by a low per cent of cyanide." Paul worked this return system through the battery, until the mill was leased to Eastern parties, who returned in their milling to the ordinary way.

Stamp Milling and Amalgamation of Free Gold Ores.

NUMBER III.

Written for the MINING AND SCIENTIFIC PRESS by DANA HARMON, San Francisco, Cal.

GREASE BOXES OVER MORTARS.—Note that the upper box C laps over box B about 1 inch, so that a small segment of the circular opening is made on box B. Along the sides of the posts, and above these boxes, nail iron flashing to throw the grease from

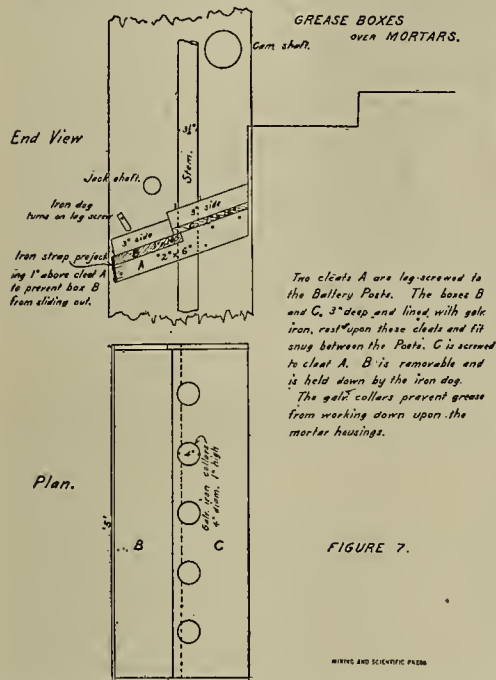

FIGURE 7.

the cam shaft boxes into these wooden grease boxes. The vibration will tear this flashing loose in a few months. Replace with new.

Albany Compound, or a similar but much cheaper brand known as New York Compound, is suitable for cam shaft boxes. For tappets, what is called commercially "gear grease" will be found to have the necessary sticky or gummy quality.

ELECTRIC LIGHTS.—To avoid breakage from the jar, the cleats and lamps should be attached not to the battery frame, but to guy wires stretched across the mill building.

ROPE DRIVING.—On mills larger than ten stamps the rope drive is decidedly the most economical, because it will run year in and year out with none of the stoppages to lace incident to the rubber belt. Every millman knows the vexatious delays and superintendents know the costs these stoppages involve by reason of reduced crushing.

Where water is the power the use of the rope drive will enable you to utilize the maximum fall from the penstock.

The drive way must be dry and should be well lighted. If the distance between the centers is so great that idler sheaves are necessary, they should be made light and with short hub length, so that the ropes will run close together, as they do on the driving sheave.

The same principle is certainly applicable to the cam shaft by placing the line shaft behind the ore bin. There should be sufficient head room on the tappet floor for a man to pass between the top and bottom ropes. It will be seen that a 20° slope admits of placing the line shaft behind the ore bin and near the ground line.

The best way to lay up a cam shaft pulley is to have all the boards radiate from the hub and to extend full length from hub to rim. Another way is to lay the boards transverse to the shaft. It may be that foundries prefer the latter method in order that a carpenter may turn off more work per week. It will be found, however, that in operation the strain of the belt and the jar tend to make the transverse boards "work," until in a short time the rim boards drop or give at every revolution of the pulley. Where the boards radiate from the hub there will be no such drop. In the one case you are depending upon the nails and bolts keeping the pulley in place; in the other you have the full strength of the fiber of the wood.

MORTARS.—Fig. 8 shows a type of mortar which yields good results both as a crusher and amalgamator on quartz. The liners are flush with the screen opening, so that there are no pockets in the mortar behind the screen. The end liners and also the bottom piece of the back liner are made of manganese steel. The front liner is of cast iron, because protected from abrasion. The wear of liners varies greatly with the ore. The important measurements

on this mortar are as follows, taken from center of stem:

On the discharge line.....	In.
On the discharge line.....	to screen 12
10 inches higher up, i. e., at top of screen.	to back 9
10 inches higher up, i. e., at top of screen.	to screen 13½
At top of new die.....	to back 9½
At top of new die.....	to screen 11
At top of new die.....	to back 6½
Length of screen opening.....	52½

It has often been suggested that instead of building so many stamps it would be cheaper to have fewer stamps for crushing coarse, as in a gravel mill (¾-inch mesh), and finishing in a Huntington or Bryan mill. Suppose that the product is to be 100 or 110

FIG. 8.

tons per day. This would call for not less than twenty-five and probably thirty stamps, costing say \$30,000. By the other plan there would be ten stamps and three 5-foot Huntingtons. The power and concentrator equipment will be practically at the same cost for either.

There will be a saving on installation of \$5000 to \$7000, but the bills for extras and wearing parts will be much heavier on the latter plan.

If the ore is hard quartz I would prefer all stamps. If the ore is soft, with an abundance of clay or dirt, the Huntington or Bryan will give the better results, as both are fine amalgamators. In fine, if the ore is so soft that the stamp pounds on the die continually, the stamp mill is not the machine required. There must always be a cushion of rock between shoe and die. It is the test of the battery man's skill to keep this cushion at the minimum, so as to barely escape pounding, and never let his mortar fill up.

MILLING.—I hold fast to four central ideas: First—On free gold ores the mortar has the two functions of crushing and of amalgamating. Second—On ores running less than \$12 per ton the method used must be such as to extract practically all the recoverable gold. We will not now discuss ores running \$40 and over, because on these a tailings loss of \$5 to \$7 may be commercially permissible. Third—If the ore is hard enough to require a rock breaker, build a heavy stamp mill, otherwise you may use one of the various rotary mills. Fourth—Do not try to economize on rock breakers. It is the cheapest initial crushing—one to the mill not enough.

There is a good deal said nowadays about high duty of the mill, i. e., large crushing. Directors relish five and one-half tons to the stamp and superintendents do not object to this high duty, because it insures low costs per ton to their mining and milling record.

I believe in crushing all possible consistent with full recovery of the gold. I can not indorse a given type of mortar merely because it is a rapid crusher. High duty should mean low tailings.

The narrow, straight-hack mortar, with low discharge, is not a new idea. The foundries are full of old patterns of this type. All our cement gravel mills are so built, but it is not enough to crush rock; one must also catch gold. Sacrifice amalgamation to crushing, and you will have the penalty of high-grade tailings.

Taking up, now, seriatim, these four captions:

THE MORTAR HAS THE TWO FUNCTIONS OF CRUSHING AND AMALGAMATING.—Gold amalgam is a slippery eel—it rolls and floats unless fairly treated. Give it a chance and it will settle in the mortar. It is not so hard to catch fine gold inside the mortar if the mortar is built for that purpose. The limit of crushing in a given mortar must be measured by the percentage of inside amalgamation, except, however, on ores carrying values of \$1 to \$1.50 per ton of fine, light gold. The aim should be to increase the inside catchment above 60%. The tendency of stamping is to combine the gold with the mercury. It is natural that this amalgam should stay inside, and it will unless the millman expels it in his scramble after a high-crushing duty.

EXTRACT PRACTICALLY ALL THE RECOVERABLE GOLD.—Whoever has used quicksilver has lost gold. Whoever has crushed ore has had uncrushed particles of sand carry some atoms of gold stowed away inside these particles. Therefore, tailings must assay something. It is a commercial question. You may be able to afford some loss in order to get through a larger tonnage. To illustrate:

Preparing a tailings sample for assay by screening

through a 40-mesh screen, we find that 2% of the sand rests on the screen, and the fire assay shows values of 5 cents or 10 cents per ton in the fine sands and \$1.50 per ton in the coarse.

The results may be tabulated:

98 tons at 5c. = \$4 90	or at 10c. = \$9 80
2 tons at \$1 50 = 3 00	3 00
100 tons = \$7 90	= \$12 80
i. e., 8 cents to 13 cents per ton.	

I am quoting actual results, not giving theories. The crushing was at the rate of 3 tons per stamp through No. 2 tin screens.

The values in this 2% coarse sand could have been saved by using No. 1 tin, but it would have been at reduced crushing tonnage and would have shaved close to the sliming danger.

I call this extracting practically all the recoverable gold.

To increase this crushing to 5½ tons and thereby the tailings to 75 cents per ton would be business suicide, regardless of whether there were 10,000 or 100,000 tons in the mine.

USE STAMP MILLS ON QUARTZ.—Somebody may invent a better machine than the California quartz mill for crushing rock and catching gold. It has its faults, and yet its much condemned sliming tendency is too often the fault of the millman. It is simple, relentless, conscientious, with fewer faults than cling to many of its operators.

If you have mud to stir, buy a rotary mill and stir it. But if you have rock to crush, build a heavy California stamp mill, with the shoe 9½ inches and the die 9½ inches diameter—the whole stamp weighing about 1100 pounds—10½ inches from center to center of stems.

More than one man has asserted that his ore did not require a heavy stamp. The man has never tried the two weights on the same ore. Nevertheless he knows, or, what is the same thing, he is sure he does know. If the ore at one mine happened to be harder than at another, he would endeavor to effect a cure by giving more drop to his light stamp. If the rock still resisted and the stamp bounced, he would settle back on the excuse that he had very hard ore, for which misfortune he was not responsible.

I have had an 850-pound and a 1100-pound stamp on the same line shaft and on identical ore. The former crushed 1½ to 1½ ton per stamp and the latter 3 to 4 tons per stamp. The light stamp could not do better, no matter what drop.

Now, then, how fast shall we run this heavy mill? What drop?

We are mixing in with factors that belong to plate amalgamation, of which later.

I want a heavy stamp because I don't want to waste time breaking rock. I want a shoe and die of large area so as to embrace many pieces of rock at every blow. If you reduce the crushing area from 9½ inches to 8 inches you are compelled to make up the deficit by speed or by a long drop.

Bring a sledge whack upon a boulder. If you don't break it, you hit harder the next blow. You don't hit oftener. Probably you will strike slower—you succeed by muscle, not by agility.

So it must be with a stamp mill. Stamp crushing is not a question of spalling rock—it is to crush and amalgamate ore that has been, as it were, already spalled by the rock breaker.

I have run mills upon unusually tough, hard ore—first-class road metal, some of it. And this is what I find: With a speed of 92 to 94, and a drop of 6 inches to 7 inches, an 1100-pound stamp will crush about 80 tons in twenty-eight days, saving practically all the gold. Increase the speed to 100 to 102, and the drop to 8 or 9 inches, this same stamp will crush about 110 tons in twenty-eight days, and give 65 to 90-cent tailings. Reducing this to dollars, there was the alternative: a tailings loss of \$300, or \$2200 per month, according as the crushing was 2000 or 3000 tons.

So, then, my rule is to get weight and area of stamp, so as not to waste time, and to drop as the tailings assays dictate.

High speed means more wear and tear, hot boxes, greater percentage of breakdowns. If you can reach the limit of profitable amalgamation by a slower speed, why not do it?

I have never run a stamp heavier than 1120 pounds. That is heavy enough.

It is easy to crush more than you can amalgamate. It is for this reason that I am unable to give assent to the theory of installing a system of rolls and crushers so as to deliver a cracked corn product to the stamps. For some mysterious reason there is benefit to amalgamation by churning rock in a mortar. I am no sufferer if it does take a little more time in the making of the hutter. If the mine needs more stamps, buy them.

Before a 5-stamp battery 5 feet width of plate seems to be the practical limit. Six feet is too wide, and 5 feet will give better results than 4.

I have tried a launder before ten stamps, the pulp being thence passed to three tables each 4 feet wide. This was a failure. By no adjustment of gates and water could even distribution and flow be obtained. One table was all sand and another all slimes. The wave—the crescent bow—was not there.

Don't economize on rock breakers. One breaker

to the mill is the rule, and ordinarily this means that much of the ore going into the feeders will not pass a 2½-inch ring. It would not cost much to cut this product to 1-inch ring size, and a very noticeable increase in crushing will result. With a 1-inch ring product there will be fewer broken stems and consequent delays.

AMALGAMATION.—

Catch the gold close to the die.
Don't use chuck blocks or inside coppers.
Don't slime by too fine crushing.
Don't crowd tables with too much pulp.
Don't sluice the pulp over the plates.
Don't add water outside the mortars.
Don't be afraid of steep grade to tables.
No distributing boxes.
Don't turn all the pulp on one-half the plate area when brushing up.

Don't scrape plates with chisel or ruhher. Ruh up with a cotton cloth and tepid water, finishing with a whisk broom. Lip plate, however, is scraped off monthly with a chisel. Old files, 1½ inch wide, make good chisels.

Feed quicksilver so carefully that never a globule of free quick appears on the plates.

Feed low, i. e., regulate the feeder so that the shoe is kept just cushioning on the die.

Run the hatteries with the splash and not with the wave motion, i. e., lift the shoe above the water at every blow. This checks the sliming of deep discharge.

Use automatic sampler on tailings.

Avoid the use of acids and cyanide on plates. Common lye will cut grease.

Keep the quicksilver clean by retorting and then washing well with dry lime. Follow this treatment with thorough washing in clean water. In lieu of this clean with a strong solution of cyanide of potassium.

Use well silvered plates. When they turn green replace them, and don't waste time and gold over nostrums.

(TO BE CONTINUED.)

The Allison Ranch, Cal., Mine.

On Dec. 3, 1902, the stamps of the Allison Ranch mill were dropped on ore from that mine in the Grass Valley, Cal., district, adding their roar to the hum of

receiving point. An automatic tipper distributes the ore uniformly to the battery bins. The battery bins form the "back-knee" of the battery frame and have a capacity of about three days' supply for the mill when in operation. The ore is delivered to the mortars by James suspended ore feeders. The battery frame is entirely of wood; the mortar blocks are set in pits excavated in solid granite. The mortars are of medium width, designed for inside amalgamation, are steel lined and constructed with roomy front openings to permit ready access to the inside of the mortar. The stamps are arranged in groups of five, ten being driven by each cam shaft, and weigh 1000 pounds each. The shoes, dies, heads, cams and tappets are of steel; the cams are steel and self-fastening. Inside chuck plates are used, and the outside copper plates, 54 inches by 12 feet in size, are arranged in movable trays. Launderers from the trays deliver the crushings to four Wilfley tables. The line shafting runs back of the mortars, close to the battery sills, in ring-oiling, rigid boxes, mounted on iron stands bolted to concrete foundations. All line-shaft pulleys are cast iron and made in halves. A 3-ton traveling crane is suspended from the trusses over the battery and a trolley is arranged under cam platform for transporting shoes, dies and amalgam safe. A clean-up harrel and retort are provided, located in a fully equipped clean-up room on level of copper-plate floor.

Power is supplied by three induction motors; one 15 H. P., driving the rock crusher and conveyor, is located in the bin at the lower end of the conveyor; one 50 H. P. drives the stamps and a 5 H. P. is provided for the concen-

503,916; other precious stones, \$3,751,333; total, \$20,723,816. For the corresponding period in 1901 the total value was \$19,895,418, showing an increase in 1902 of \$828,398, or 4.2%.

An Experiment in Amalgamating Auriferous Sulphides.

At the Black Oak mine, near Soulshyville, Tuolumne county, Cal., Superintendent Guy Scott has been making some interesting experiments in amalgamation of the auriferous sulphides of that mine. These sulphides are chiefly pyrite, pyrrhotite and chalcopyrite, with smaller quantities of galena and zinc blende. The sulphides were taken from the vanner washing boxes and placed in an iron vessel made from a piece of 6-inch pipe, 18 inches in length,

Allison Ranch Mine, Nevada County, Cal.

Mill, Allison Ranch Mine, Nevada County, Cal.

Mill and Elevator, Allison Ranch Mine, Nevada County, Cal.

activity that has characterized the valley in which the mining plant is located since the property was taken over by its present owners about six years ago.

The mill is a 20-stamp gold mill, with copper plates and concentrators and is driven by electric power. It is located on the side hill on Wolf creek opposite the hoisting works, about 400 feet from the point where the ore is received from the mine cars and 67 feet higher than the collar of the shaft. The location of the mill at a distance from the hoist was necessary on account of the large waste dump, covering the entire space near the works, and on which suitable foundations could not be obtained, and the desire to secure grade for the proper handling of the ores within the mill. The designers have skillfully worked out the problem of transporting, elevating and delivering the ore to the mill economically and conveniently. By means of cars, the ore passes from the mine to an ore bin built near the hoist, where the ore is screened over grizzlies and the coarse reduced by a 9x15-inch Giant breaker to pass a 1½-inch ring. The bin holds thirty tons of ore. A gate in the bottom of the bin is opened and the ore passes onto an inclined belt conveyor, which delivers it to the ore bins in the mill, 240 feet away and 50 feet higher than the

trators. Substantial buildings cover the ore bin and rock breaker; a suitable house on a trestle completely covers the beltway. The mill building is of substantial construction and pleasing design. Wings from the main building form the clean-up room and a dry house for drying and storing sulphurets. Concrete or matched board floors, easy stairways, handrail-protected platforms and beltways, numerous windows well distributed, well-arranged launders and drains, make up a complete and perfect mill. The building is lighted with electricity. The buildings are of wood, uniform in appearance with the hoisting works, compressor house, shops, etc., making a pleasing whole. Under the direction of Superintendent Robinson, the mill is running successfully.

The mill is from plans and specifications of Harron, Rickard & McCone of San Francisco, Cal., which firm built the plant, turning the same over to the mining company in complete working order.

IMPORTS OF precious stones into the United States for the ten months ending October 31 are valued by the Treasury Department as follows: Diamonds, uncut, \$5,379,567; diamonds, cut but not set, \$11,-

and provided with a screw cap on each end. One end is closed, and a quantity of the sulphides placed in the vessel with a small amount of quicksilver and water.

A piece of stamp stem, nearly the length of the vessel, is then inserted, and the vessel clamped horizontally in a turning lathe, and revolved for several hours. The section of stamp stem acting as a muller grinds the sulphides to a fine state of division and permits the gold thus mechanically freed to unite with the mercury. By this simple means, though only an experimental test, Mr. Scott says he extracts 90% of the assay value of the gold, the tailings being subsequently treated by cyanide solution by agitation with a recovery of a high percentage of the remainder of the gold. How this will work on a commercial scale remains to be determined. The method employed in making the experiment is novel, although the fact that gold in sulphides could be amalgamated by fine grinding has long been known.

Experimenting in this way often leads to important results, and the application of this method to the treatment of sulphides on a commercial basis is of great interest.

The Verde Mining District, Yavapai County, Arizona.

Written for the MINING AND SCIENTIFIC PRESS by
G. W. MILLER, E. M. C. E.

This district, one of the oldest known mineral localities in Arizona, received a new impetus about a decade ago, by the transformation through W. A. Clark of the United Verde mine. Up to that time the property had been an unprofitable silver-

yet by following the contour of the mountains no more extraordinary difficulty was encountered by the engineers in bringing the railroad into Jerome than is generally met with in other mountainous regions.

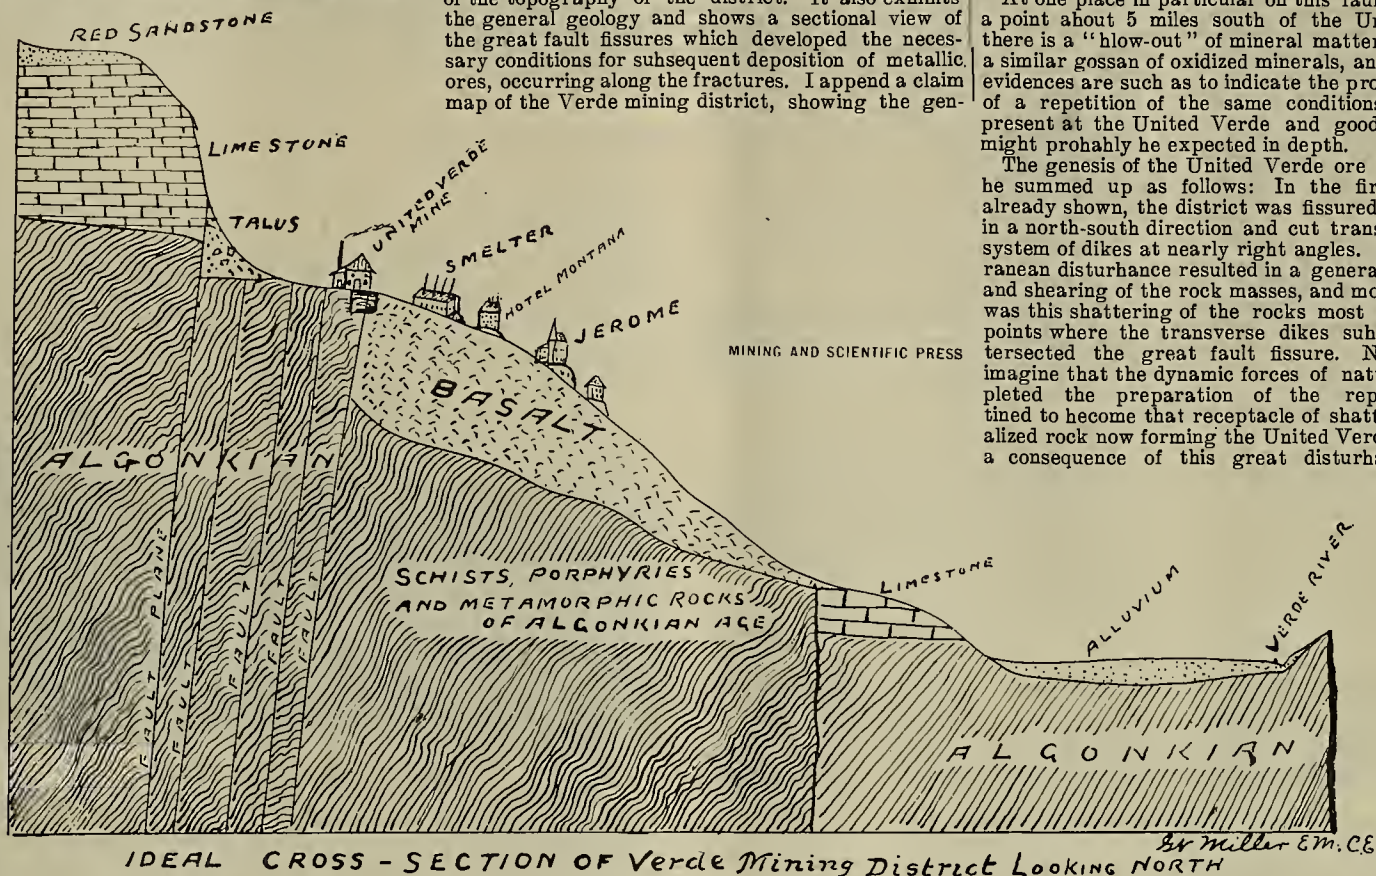

My description of this district shall be confined to the geology and economic peculiarities of this property. I take the United Verde mine as a typical geological representative, as it is the only property extensively developed in the district.

The accompanying ideal cross section through the Black Hills range is intended to give a general view of the topography of the district. It also exhibits the general geology and shows a sectional view of the great fault fissures which developed the necessary conditions for subsequent deposition of metallic ores, occurring along the fractures. I append a claim map of the Verde mining district, showing the gen-

heaval of the mountains, subsequent to the deposition of the red sandstones and associated with the basalt flows. Along this particular series of fissures is a vast mineralized mass of laminated, altered rocks, belonging to the "Basal Complex," and containing low-grade ores for a distance of 2000 feet in a northerly and southerly direction by 450 feet in an easterly and westerly direction. This particular ore belt extends through the "Basal Complex," much intruded by volcanic rocks, for a distance ranging from 12 to 18 miles, and shows small ore deposits in place at various points.

At one place in particular on this fault fissure, at a point about 5 miles south of the United Verde, there is a "blow-out" of mineral matter, exhibiting a similar gossan of oxidized minerals, and where the evidences are such as to indicate the probability here of a repetition of the same conditions that were present at the United Verde and good copper ore might probably be expected in depth.

The genesis of the United Verde ore deposit may be summed up as follows: In the first place, as already shown, the district was fissured and faulted in a north-south direction and cut transversely by a system of dikes at nearly right angles. This subterranean disturbance resulted in a general shattering and shearing of the rock masses, and more especially was this shattering of the rocks most extensive at points where the transverse dikes subsequently intersected the great fault fissure. Now we may imagine that the dynamic forces of nature had completed the preparation of the repository destined to become that receptacle of shattered, mineralized rock now forming the United Verde mine. As a consequence of this great disturbance of the

IDEAL CROSS - SECTION OF Verde Mining District Looking NORTH

gold and copper producer for over a quarter of a century. It has been, during the last decade, and down to the present time, a sensational and far-famed copper mine.

This mining district is situated on the eastern slope of the Black Hills range, about 1500 feet vertically below the summit, and at an altitude of between 5000 and 6000 feet above sea level. It is

eral course of the fault fissures, and also a geological, longitudinal section, made to a scale of 1 inch, equalling 500 feet. This longitudinal section shows the ore deposit and mine openings of the United Verde mine.

The geological history of the district may be summed up as follows:

First, an immense upheaval of the various sedi-

earth's crust, subterranean waters impregnated with minerals in solution flowed up from the depths below to begin the task, to be carried on for countless ages, of depositing their metallic burden in the innumerable rents of the previously outlined ore deposits, while these mineral waters steadily circulated through them.

Still further explanation of this remarkable chemical phenomenon seems necessary, in that the pay ore of this deposit lies in shoots or distinct outlined pockets; and also close observation reveals the fact that the ores possess or retain in some instances the texture of the surrounding rocks of the "Basal Complex," thus naturally suggesting the probability of a chemical transformation of the former into the latter. This process of mineral deposition is known to geological science as "metasomatism," and it is here beautifully illustrated as representing one of the most potent agencies to which may be ascribed the true theory that accounts for and explains the natural process which operated to form the ore deposits. Thus we may suppose that the ores were obtained metasomatically, that is, there was a molecular substitution of the minerals contained in the circulating waters for particles of the shattered country rock. This interchange was atom for atom until the shattered mass of rocks had become replaced by metaliferous substances and the displaced country rock taken into solution and carried away.

The occurrence of two distinct ore shoots, to which all the pay ore of the mine is confined (see drawing), may be accounted for on the hypothesis that

these chutes mark ancient water channels, where the agencies of mineral deposition operated more effectively and perhaps were confined to these certain points more exclusively or for longer periods of time.

This mine, as stated above and shown in drawing, comprehends a vast mineralized chamber in so-called diorite (improperly so named by the miners) 2000 feet long by 450 feet wide, the pay ore of which is limited to two regular shoots, the average longitudinal length along the zone of mineralization of each being about 300 feet. These extend transversely across the zone of intervening poor ground for a distance of 450 feet. The surface outcrop of these chutes is rendered particularly conspicuous by the

GEOLOGICAL-LONGITUDINAL SECTION OF THE UNITED VERDE MINE Jerome Ariz. SCALE 1 INCH TO 500 FEET

about 20 miles in an air line northeasterly from Prescott.

The town of Jerome, the commercial center of the district, and where the United Verde mine and smelters are situated, is accessible from Prescott Junction, on the Mineral Belt Railway, a distance of 26 miles over the U. V. & P. Railroad. The watershed of the district drains into the Verde river, at a distance of about 6 miles from Jerome. This stream meanders in a southeasterly direction through what is properly termed the northwesterly continuation of the great Salt River valley, the Verde river being a tributary of Salt river.

The general topography of the country is abrupt,

mentary and igneous rocks of the district, attended with a complex system of fracturing, of which the master fissures were north and south and the others transverse. An attendant phenomenon was the outbreking of volcanic rocks, principally basalt. There is much that might be said about the older rocks. I refer to the red sandstones and shales and the thin-bedded limestones, as well as the schists and slates and porphyries known as the "Basal Complex," upon which the former rest unconformably, as will be seen by reference to cross section before mentioned.

The so-called great fault fissure, in which the United Verde ore body occurs, is one of the north and south fissures produced at the time of the up-

presence of an immense gossan, or iron hat, as the Cornish miners would say. From the open cut on the south shoot (see drawing) many thousands of tons of oxidized gold and silver-bearing ores have been quarried out during the early history of the camp, the copper values having been leached and subsequently concentrated at greater depths. These shoots extend to or below the 700-foot level. The ores contained in them consist principally of the copper minerals: hornite, the black oxide of copper melanconite, a very hard impure variety of chalcopryrite, some red oxide (cuprite) and frequent efflores-

stroke, the area of the piston and the mean effective pressure multiplied by the number of revolutions per minute.

Pyritic Smelting.

True pyritic smelting has not yet been accomplished. By true pyritic smelting is meant the fusion of sulphide ores without the aid of other fuel than the sulphur contained in the ore itself. Still, runs of twenty-four hours at a time have been made without any outside fuel, but slight irregularities

we have available only 1291 calories per gram. The calorific power of carbon is 8080.

Attempts have been made to devise furnaces which would utilize the heat of the two sulphur atoms, but the system of larger charging is in general use.

The regular use of a small amount of coke has been found beneficial, not only on account of the extra heat, but also because of its helping to keep the furnace charges porous. It will also keep solid until consumed, while the pyrite has a tendency to fuse and trickle down the air passages. A large volume of blast is used through numerous tuyeres of large area, and everything is done to make the process entirely an oxidizing one.

Since the pyrite is apt to fuse, it is kept in the furnace as short a time as possible, whence comes the use of a short ore column.

Hot blast is not essential to the process, but it tends to correct variations in the furnace, causing it to run more regularly, and is almost a necessity when highly siliceous slags are to be used, in order to keep them at a sufficient temperature to flow properly. Its advantages are: First, the extra heat it brings in causing less necessity for fuel; second, less fuel gives less consumption of oxygen, and so the oxidizing power of the blast is not reduced by forming CO_2 ; third, resulting from the higher oxidizing power of the blast will follow a higher sulphur content of the charge; fourth, it gives a more energetic action and increases the hearth temperature; fifth, cold blast will cause the temperature to rise in the shaft, while a hot blast will bring about a lower position of the fusion zone; sixth, the increased temperature will permit the use of more siliceous, hence cheaper, slags.

The advantages to be gained by pyritic smelting are enormous, and if the true process can be developed there will be no further fuel hills; as it is they are reduced more than half. There is no time wasted or skilled labor required in roasting, and the extra expense of building a roasting plant for the purpose of destroying the fuel which nature stored in the ore is avoided.—Journal Chemical and Metallurgical Society, South Africa.

The El Mundo Process.

TO THE EDITOR:—The El Mundo process consists of roasting at a low heat pulverized ore or concentrates, with such ingredients as serve to follow nature in her oxidizing work, but which this process accomplishes in from a few minutes to two hours. The principal ingredients used are common earth, sawdust, charcoal, unburned lime and nitre. No one ore requires the use of all these ingredients, but all ores require the use of one or more. The use of common earth serves two purposes, one to furnish a base into which the sulphur and arsenic goes and is again immediately set free, passing out as fumes; the second purpose is to furnish a cupel in which to absorb the fine gold from tellurium or other ores carrying fine gold and hold it in suspension until it can be brought in contact with mercury in amalgamation. The sawdust has two purposes, one to furnish carbon and the other hydrogen. The chemical combination formed by mixing the required ingredients with pulverized ore or concentrates and subjecting them to a heat of from 350° to 450° Fahrenheit, has the effect of quickly oxidizing all the base ingredients, and changing the gold and silver to metal where it exists otherwise. When there is either sulphur or arsenic present they both pass out as fumes. Zinc and lead become oxides and also pass out in fumes. The mass is roasted in an oven with free access of air from both sides. The flames pass under the ore. The importance of this becomes apparent when millions of particles of sulphurets can be seen hursting into bright sparks, filling the entire oven. With an overheat these hursting sulphurets, each containing a small particle of gold, would be carried out and scattered over the surrounding country.

The importance of the El Mundo process to the mining world is that any sized plant can be installed at the mine and all ores worked independent of transportation. The mine that produces but a few tons of concentrates per month can fire up an oven, roast what concentrates are on hand, feed the roasted ore back into the mill while crushing rock and amalgamate it the same as any other free milling ore. When the ore contains talc or other ingredients that would prevent crushing by stamp mills and concentration the ore can be crushed by rolls and the whole mass roasted. The cost of treating ore by El Mundo process is nominal.

THE INVENTOR.

[The above described process is said to possess merit, where it has been tried upon the ores of Tuolumne county, Cal. When divested of what seem to be its inessential features, it simply resolves itself into a process wherein oxidizing agents are employed, viz: charcoal, sawdust and nitre, in roasting pulverized sulphide ores. These ores may be the crushed material as it comes from the mine, or concentrates. The ores are roasted in an oven without draft, thus lessening the loss, in the form of flue dust, which is incident to all processes where the fire is

cence of blue copper sulphate or chalcantite. The mine is opened up by two main working shafts each 750 feet deep vertically. These are connected by levels which are in the deeper workings 100 feet apart (see longitudinal section).

Butte, Mont., Jan. 24, 1903.

The Science of the Flywheel.

Increasing the size of a flywheel will not increase the amount of work your engine will do, says Practical Engineer. The function of the flywheel is to produce a uniform motion. When the engine is "on the center" practically all the moving force of the engine comes from momentum of the flywheel. When the full force of the pressure is upon the piston this force is obliged to overcome the inertia of the flywheel. In this way the excessive force moving the engine is decreased and the defective force increased at the proper time by the momentum of the flywheel, thus insuring a proper regulation of speed. The capacity of your engine is equal to the product of length of

compel a blowout, and so partial pyritic smelting or the addition of some coke to the charge is used at present.

Matte smelting as defined by Lange being "the smelting of ores composed of, containing or giving rise to sulphides for the purpose of collecting their slimes in a less quantity of artificial sulphides," pyritic smelting can be considered as a division under matte smelting, in that the matting and smelting operations are carried on at the same time in the same furnace.

If we compare the relative heating power of carbon and sulphur we find that carbon is much the better fuel, but the combination of sulphur, if the heat can be utilized, is sufficient to retain all the products in a thoroughly molten condition.

When pyrite is roasted we find that one atom of sulphur is given off readily, but the other one clings to the iron much more tenaciously, and on its combustion we have to rely for our smelting heat, as the first atom is given off at the top of the furnace and is not available. If this could be utilized the calorific power of FeS_2 would be 1523, but with FeS as a fuel

MINING AND SCIENTIFIC PRESS

Electrically Operated Oil Circuit Breaker.

A few years ago most alternating-current switchboards were equipped with hand-operated knife switches. It is now found advisable to use some means of auxiliary control. This permits the actual current-switching devices to be located with regard to the general design of the station and a satisfac-

first at the main contacts and then afterward at a removable plug attached to the stationary contact which enters a hole on the movable contact.

Mounted on each circuit-breaker is a small double-pole, double-throw knife switch, which is used with the indicating and tripping circuits, and is operated by the motion of the levers of the circuit-breaker. The controlling and indicating devices consist of a controlling switch, an electro-mechanical, tell-tale indicator and a lamp. These are suitably mounted at the operating platform. A poly-phase overload relay, connected to series transformers in the main circuits, is provided for automatic opening. The controlling switch, which is of the drum type, has three positions, namely, "closed," "off" and "open." It will remain of itself in the "off" or the "open" positions only. If thrown to the "open" position, it will remain in that position when the hand is removed; but if it is thrown to the "closed" position, it will turn of itself to the "off" position as soon as the handle is free. In the "off" position it connects the control circuit, so that if the oil circuit-breaker opens, through the action of any of the automatic devices, the lamp will be lighted on the operating stand to attract the operator's attention. If the oil circuit-breaker is opened by the operator throwing the controlling switch to the "open" position, the lamp does not light.

The mechanism of the electro-mechanical tell-tale indicator consists of an electro-magnet, which attracts a pivoted armature through an angle of about 90°. Attached to the armature is a disc with a pointer, which indicates to the eye the "open" or "closed" position of the oil circuit breaker.

In the accompanying illustration the closing magnet is partly hidden by the overload relay. This operates on the principle of the single-phase induction motor. Each of the sectors swings between the poles of an alternating-current electro-magnet. Part of each pole is surrounded by a short-circuited strip of copper, which acts to retard the magnetic flux and thus produce a shifting field. This tends to move the counter-weighted sectors, which carry a contact, closing the tripping circuit of the circuit breaker. The two sectors are connected in parallel, and either alone will trip the breaker. The currents for their magnets are derived from the phases of the main circuit by series transformers.

The engraving shows the left-hand compartment closed by an iron door, the oil tank suspended in the middle compartment, and the right-hand compartment without the oil tank. The overload relay is just above the second brick pier from the right, and the tripping device just above the third pier.

The apparatus described above, known as the "Type C circuit-breaker," is manufactured by the Westinghouse Electric & Mfg. Co.

A Quadruple Horizontal Pump.

The pumping plant of the Iowa Mining Co., Fresno county, Cal., consists of a setting of four 5-inch Jackson horizontal centrifugal pumps, arranged to work singly or compounded. This plant, when compounded, delivers 1000 gallons per minute, at an elevation of 50 feet, through 1500 feet of discharge pipe with a pressure at the point of discharge of 115 pounds, and is used for hydraulicking purposes. This machinery is driven by a 62-inch Sampson water wheel. Another plant of this character is that of the Bay Counties Power Co., installed recently near Dobbins, Cal. This plant consists

of two special 10-inch horizontal centrifugal pumps, compounded, is belt-driven and works under a head of 400 feet. The efficiency of this plant is stated to be 47%. During the past six months the Byron Jackson Co. of San Francisco, Cal., has supplied several pumping plants for irrigation and city water works east of the Rocky mountains. The Jordan River pumping plant near Salt Lake City, Utah, consists of four special 40-inch Jackson centrifugal pumps, having a combined capacity of 200,000 gallons per minute, each pump being belt-driven by one 100 H. P. electric motor. The pumping plant for the city of New Albany, Ind., recently supplied, consists of two specially compounded 8-inch centrifugal pumps and works under a head of 300 feet capacity of each 1400 gallons per minute. The plant for the city of Danville, Ill., consists of two special 12-inch horizontal centrifugal pumps with capacity of 5000 gallons per minute at variable heads. There is now in construction in the works of the company special pumps and apparatus for the cities of Forth Worth, Texas, and Elgin, Ill. Among city water works, pumping plants installed in California during the past few months are those of the city of Modesto, consisting of one 85 H. P. automatic steam engine, with special Jackson centrifugal pumps, which furnishes water for both domestic and fire purposes. The pumping plants for the cities of Woodland and Colusa consist of special Jackson high-head pumps driven by direct-connected electric motors.

No BRANCH of the iron industry carried on in the region of the Great Lakes receives more attention than that of ore handling and transportation. There is a continual increase in the capacity of ore carrying vessels. The development of mechanical appliances for handling ore from the docks to vessels and from vessels to docks has reached a most interesting stage. Where a few years ago most of the ore was moved by hand, or aided only to a limited extent by the employment of mechanical means, now great swinging cranes handle thousands of tons of ore daily, and to the casual observer it appears the limit of capacity and economy has been reached; but that this is the case is unlikely, for while the newest devices are the most complete, others of still greater capacity and operating economy are being planned.

The earliest data respecting mining shows that the necessity of engineering skill was recognized in the pursuit of the business. The few copies of Agri-cola extant in its ancient parchment binding has many rude wood cuts showing men at work underground, with engineers engaged in taking levels or establishing angles by means of plummet and level. Some of these cuts also show the methods of timbering employed in those "early days." In most cases the timbers were not framed, but were selected and cut with the forked limbs. These were used as posts which were employed to support caps laid on the fork. None of these timbers appear to have been framed.

The temperature of a furnace may be determined by means of a small carbon filament incandescent lamp, fitted inside a telescope mounted on a tripod some distance from the furnace, and pointed at an aperture. When no current is passing through the filament it appears as a black line against the background of white-hot firebrick. As more current is sent through the filament becomes brighter until when it attains the same color as the glowing furnace it is invisible. By a further increase of current it becomes visible again. The value of the current is read on an instrument, and a comparison with a table gives the corresponding furnace temperature.

The ore sent from Canyonville, Or., is chromite or chromic iron ore. It occurs in "bunches" or deposits of greatly varying size, some of them containing many tons of marketable ore. Often it is found in a series of deposits connected by small vein-like leaders. The standard ore is one containing 50% chromic oxide, and for each unit above that amount from 75 cents to \$1 is paid; but a much greater deduction is made for every unit below 50%. The average value of chromic iron is about \$10 per ton.

Automatic Circuit-Breaker.

tory lay-out of circuits and apparatus, and centralizes the control within a small space. It is to supply a compact and reliable device for rupturing high-tension circuits that the oil-break circuit-breaker has been developed. The accompanying illustration shows a three-pole, double-break, automatic, oil circuit-breaker, operated by electro-magnets. The circuit-breaker is erected in a masonry structure, with each pole and oil tank in a separate fireproof compartment. There are two stationary contacts to the pole, one connected to the incoming lead and the other to the outgoing lead of the same phase, each contact being mounted in a large porcelain insulator. In the illustration one of the porcelain insulators shows in the right hand compartment.

The insulators are fastened to a cast iron frame, which also supports the enclosing oil tank. The frame itself is supported from the soapstone slab at the top of the masonry walls by strain insulators. The movable contact for each pole consists of a U-shaped piece of copper fastened to the end of a stout wooden rod. In the closed position of the switch one of these U-shaped pieces electrically connects the two stationary contacts of each pole. The wooden rods are fastened at their upper ends to a common crossbar, which extends over the three masonry compartments and is supported by a system of levers giving a straight-line up-and-down motion. The crossbar is raised by the enclosing magnets, assisted at the beginning of the motion by a pair of balancing springs. The springs and the case containing the magnet are at the upper right-hand corner in the illustration. A toggle joint, shown at the left in the illustration, automatically locks this system of levers when the circuit-breaker is in the closed position.

The toggle joint is released by a blow from the tripping magnet, whereupon the crossbar, under the influence of gravity and a powerful spring, quickly drops, opening the contacts. The break takes place

Quadruple Horizontal Pump, Iowa Mining Co., Fresno County, Cal.

Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 20, 1903.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

PROCESS OF SEPARATING PRECIOUS METALS FROM MATTE.—No. 718,601; F. R. Carpenter, Denver, Colo.

Process of separating precious metals from matte which consists in subdividing matte into small, smooth shot-like grains, and then leading matte, leading being maintained at temperature insufficient to fuse matte, but sufficient to cause absorption of precious metals from it.

SMELTING FURNACE.—No. 718,726; F. B. Petten-ill and E. Nicholson, Los Angeles, Cal.

Smelting furnace, comprising smelting chamber having composite lining around sides thereof, lining composed of spaced water tubes connected to hollow headers and firebrick therebetween; combustion chamber in communication with smelting chamber, having composite lining around sides and top thereof, composed of spaced water tubes connected to hollow headers and firebrick between tubes.

AIR HEATER FOR SMELTING FURNACES.—No. 718,755; J. L. Giroux, Jerome, Ariz.

Combination with smelting furnace of horizontal heating coil in upper portion of furnace, series of vertically disposed pipes surrounding interior of upper part of furnace, and connected with terminal of heating coil, and pipes of series made divergent from one end to other, and having alternate ends connected to form tortuous passage, inlet by which air is admitted under pressure at one end, outlet from opposite end, and connection between outlet and surrounding trunk or bustle pipe, and pipes leading from trunk to tuyeres of furnace.

GOLD EXTRACTING PROCESS.—No. 718,633; T. B. Joseph, Mercur, Utah.

Process of extracting gold and silver from ore containing same in suitable condition, which consists in subjecting ore to leaching action of solution of water, cyanide of potassium, hydrate of calcium and carbonic acid gas, gas being forced into leaching solution simultaneously with compressed air.

FURNACE FOR TREATING METALS.—No. 718,760; H. D. Hibbard, Plainfield, N. J.

Furnace for treating articles of metal, comprising elongated heating chamber having near one end at one side heating means and at same end on opposite side outlet flue for products of combustion, and plurality of partitions between hot end of furnace and its opposite end, partitions being movable into and out of path of charge, whereby series of consecutive heating zones may be obtained having temperature gradually increasing from zone to zone without interfering with passage of charge.

EXCAVATING MACHINE.—No. 718,854; D. W. Miller, Chicago, Ill.

In excavating machine, combination with suitable supporting frame, of excavating wheel of rigid construction provided with series of peripheral scoops arranged with their longitudinal axes perpendicular to radii of wheel and located at periphery thereof, each scoop having open front end and provided at rear with swinging door; means for automatically releasing several doors of scoops at predetermined point in rotation of wheel, fixed guide apron mounted in rear of each scoop and adapted to direct excavated material downwardly and radially outward, stationary receiving apron mounted upon supporting frame in position to receive excavated material from moving aprons, and conveyor belt arranged to receive material from stationary apron.

GRIPPING DEVICE FOR WELL BORING APPARATUS.—No. 718,937; H. G. Johnston, Corsicana, Texas.

In well drilling apparatus combination with rotary plate or table, means for rotating same, means for gripping well tube so as to rotate same without interfering with its endwise movement, consisting of longitudinally apertured blocks, two parallelly ar-

anged screw-threaded shafts carried by rotating plate, each one of which is provided with a centrally, vertically apertured enlargement which rests on boss carried by plate, which boss is provided with reduced portion or pin which extends through vertical aperture of enlarged portion of screw-threaded shafts, internally threaded sleeve nuts carried by shafts and also extending through blocks, sleeve nuts being provided with enlargements or heads to bear against the blocks, plain shafts extending at right angles to threaded shafts and extending transversely through blocks and provided with nuts on outer ends to hold them in position on blocks, gripping jaws or rings carried by plain shafts and constructed to rotate on same, and blocks arranged on plain shafts for properly spacing gripping jaws.

DEEP-BORING MACHINE.—No. 718,876; V. Petit, Stryj, Austria-Hungary.

In well boring machine combination of boring tool, vibratory structure, means for vibrating structure, flexible device carrying tool at one end, coating rotary gripping members engaging flexible device and mounted in structure, worm wheels formed one with each gripping member, and worm engaging worm wheels.

METHOD OF REDUCING METALLIC OXIDES.—No. 718,891; E. G. Acheson, Niagara Falls, N. Y.

Method of reducing metallic oxides, which consists in placing in proximity to electric conductor oxide to be treated mixed with reducing agent in proper proportion to reduce oxide to elemental state, placing between conductor and such mixture layer of pre-formed refractory carbide and passing electric current through conductor.

BLAST FURNACE.—No. 718,945; L. Bentley, Columbus, Ohio.

In a blast furnace, downtake, upwardly leading portion therein, and horizontally extending projections on inner side of upwardly leading portion to obstruct passage of dust particles through upwardly leading portion.

Mining Summary.

Specially compiled and reported for the
MINING AND SCIENTIFIC PRESS.

ALASKA.

W. E. Thorne, of Denver, Colo., has gone to Forty Mile to install and manage a hydraulic mining plant on the North Fork of Forty Mile creek, 95 miles above its confluence with the Yukon, for the Big Bend M. Co. of Chicago, Ill. An unusual condition is found at Big Bend. This portion of Forty Mile creek has a light grade, and has made a horseshoe shaped bend, the distance around the bend being 2½ miles. A trench has been cut across the neck 70 feet in length which with a fall of 23 feet drains the bend completely. A 5-mile flume from Hutchinson creek will deliver 3000 inches of water for hydraulicking under 300-foot head. The gravel is stated to average 8 feet deep, and 100 yards wide around the bend. Owing to the flat grade the tailings will be handled with hydraulic elevator. The company has a sawmill on the property and is getting out lumber for the flumes. Mr. Thorne expects to reach Dawson by Feb. 15, and all machinery and supplies will be taken in during winter as transportation is difficult and uncertain when the ice is gone.

The Jualin M. Co. will begin this spring to mine in their lower levels, says Superintendent Haggatt, and the shaft sunk to 500 feet. The Jualin mine is at Berner's bay, near Juneau.

ARIZONA.

COCHISE COUNTY.

Superintendent J. Mitcheson says development will be resumed on his mines, 1 mile from Gleeson.

Manager G. M. Henry, the Dragon M. & S. Co., in the Dragoon mountains, 18 miles from Tombstone, says sinking the shaft will be resumed and go down to 750 feet.

Two and one-half miles from the Modern, near Bisbee, Jones, Erickson & Davis have struck ore assaying 20% copper and \$1 in gold, in a tunnel 50 yards from the road. They have a group of six claims.

W. J. Burner of Ramsey canyon is driving a tunnel to develop his three copper claims on the right fork of Ash canyon. Campbell & Cummings are developing a group of three gold claims in Ash canyon. They also have copper prospects at the head of Copper canyon. Mrs. J. W. Stump owns three gold claims above Lefebvre's camp, out of which her lessees last week made two shipments of \$100 ore. The shipments were made from the east location, the ledge averaging 36 inches in width.

The Marquette & Arizona M. Co., near Bisbee, will put in an engine and hoist with a capacity of sinking 1500 feet.

At the Golden Era, near Bisbee, the shaft is down 125 feet.

The Copper Queen M. Co. at Bisbee has let a contract for 1000 feet of 10-inch air pipe.

It is expected that the plant at Benson will be completed by March 1.

GILA COUNTY.

The Gray at Globe, belonging to the United Globe or Phelps-Dodge system, is flooded, the pumps being under 200 feet of water, says the Bisbee Review.

The 30-ton concentrator at the Yo Tam-hien mine, near Globe, is nearing completion and an aerial tramway 900 feet long and 300 feet of surface track will be put up.

Superintendent E. H. Benson of the Black Warrior C. Co., near Globe, says he is putting in the foundation for a leaching plant which will include six lead-lined tanks of fifty tons capacity each.

GRAHAM COUNTY.

Last week the drift being run from the incline shaft of the Standard copper mines, near Clifton, cut a lead of glance ore 19 inches in width.

The Sierra de Oro G. M. & M. Co. of Arizona has been organized by Crawford, Potter & Morrow to develop a group of gold claims in the Greenlee district, 4 miles above Clifton. There are fifteen claims in the group and a millsite on the Frisco river, containing in all 305 acres.

MOHAVE COUNTY.

(Special Correspondence).—Owners of the Burro mine, at Owens, on Burro creek, after an idleness of many years, are building a wagon road from Sandy river to the mine, a distance of 8 miles, and expect to do considerable development work and erect a mill; J. P. Wallace is manager.

W. H. Chapman of Owens has a group of five claims, 1½ mile from the Big Sandy

river, showing good values in gold, silver and some copper.

Kingman, Jan. 19.

(Special Correspondence).—Chloride, 27 miles north of Kingman, is reached via the Arizona & Utah Railway. The veins here are fissures running northwest-southeast—the mineral belt commencing near Cerbat and Stockton Hill and running through Mineral Park and Chloride to White Hills, a distance of 40 miles. The camp at Chloride was worked thirty years ago. The surface ores were bailed to different points on the Colorado river, going via Lower California to San Francisco—later via Yuma to San Francisco. The first mill built in the district, at Mineral Park, charged \$50 per ton for treatment, paying 80% of the value, and at that time there was a State tax. At Mineral Park the K mine has a tunnel in 50 feet and a crosscut 30 feet. Ore runs \$80 per ton. The King mine at Mineral Park has a tunnel in 80 feet and taking out ore running 600 ounces silver. The ledge is 10 inches wide.

The Oro Plata M. & M. Co. at Campbell are building a 40-ton concentrating mill. Same will be ready about February 10. The mill is being erected by E. E. Stephens. Machinery used will be one crusher and five concentrators, 45 H. P. boilers and 35 H. P. engine. The company owns four claims carrying gold and silver. Four hundred thousand dollars has been taken from the property and shipped in former years. They have a shaft down 250 feet and a 900-foot tunnel. J. D. McNab is manager; H. J. Woolcott, of Los Angeles, Cal., president.

The Queen Bee, near Mineral Park, has the new shaft down 70 feet and are putting in a gasoline hoist. At Chloride the Chloride G. M. Co. has a lease on the Fourth of March and the Samoan; L. Hoffman, president and general manager; J. H. Hoffman, Marble, Colo., secretary; C. Hoffman, Enterprise, Kansas, vice-president. All royalties apply on purchase price. These properties were worked for a time by leasers, who took out only high grade ore. No work has been done since 1897. All has been dead work since November. The shaft on the Fourth of March is down 100 feet and sinking to 200 feet, when they will install a hoist. The ore is sulphide, carrying gold, silver, iron and lead, running from \$50 to \$100 per ton. Twenty thousand dollars of ore was taken out by the leasers. The vein varies from 8 inches to 3 feet. They have shipped three carloads of ore to the smelters. The main tunnel on the Samoan is in 400 feet with drifts and stopes 150 feet. The upper tunnel is in 300 feet. They will drive the lower tunnel 50 feet farther and upraise the winze from upper tunnel. The mines are 3 miles from the railroad and near the summit of the Wallapai range. Twelve men are employed.

Kingman, Jan. 20.

(Special Correspondence).—The Tennessee mill, one-half mile from Chloride, operated by the Hualapai M. & D. Co., is handling 100 tons of ore per day. Shaft No. 2 is down 600 feet. The Elkhart, one-half mile north of the Tennessee, has an incline shaft down 500 feet, from which Superintendent C. Barmore, Jr., is driving a crosscut by hand and expects to get water enough for the mill and other purposes. The mill has been overhauled and additional machinery put in. The ore hoisted from the mine is taken on an incline tramway up to the mill on the north. The mill contains a crusher, one set 14x27 and one 16x30 rolls, trommels, three jigs and two concentrators, requires four men, and has a daily capacity of 125 tons. Ore is galena, carrying gold and silver. Oil is used for fuel. The Schuykill group, south of the Elkhart, has been closed down for several months. Chloride, Jan. 21.

Manager J. P. Wallace says he will install a mill on the Burro mine, near Kingman.

PIMA COUNTY.

J. P. Owens, of Owens, Tex., has sold the Tres Amigos gold mine and the Sorrel Top mine, of the Oro Blanco mining district, to Pettigrew and associates.

Manager J. B. Stetson, the California Co., has 40 men at work opening a 6-foot ditch 5 miles long, near Greaterville, to the placer mining district. Three miles of 24-inch pipe will be laid and a reservoir constructed on the east slope of the Santa Ritas. Greaterville is 40 miles southeast of Tucson.

PINAL COUNTY.

The Fernando M. & D. Co. of Los Angeles, Cal., are developing a group of five mines, 45 miles north of Tucson.

SANTA CRUZ COUNTY.

Ore is being shipped from Washington camp to the smelters.

YAVAPAI COUNTY.

Superintendent B. Blanchard of the

Iron King mine, near McCabe, says forty men are at work and the 200-ton plant will be in operation next month.

A hoist will be set up near the 200-foot shaft of the Leland M. Co., near Prescott. E. Wells is superintendent.

J. Kompatscher and L. Martin claim to have rediscovered the telluride vein in the Montgomery mine near Prescott.

L. Thomas and Gibbons Bros. are building a mill on their Contention mine, near Prescott. Their ore runs \$15 per ton gold.

Manager W. D. Wasburn, the Sultan mine, near Prescott, says they will install a reduction plant and hoisting machinery to develop the property. H. L. Montague is superintendent.

Superintendent W. H. Ferguson has men at work developing the Hurricane mine of Douglas, Lacey & Co., 8 miles from Prescott.

The Mercantile M. Co., near Prescott, will put in a steam hoist.

The Miners' & Prospectors' D. Co. is opening up a recent find in the King of the West mine on Little Cripple Creek, one of a group owned by this company. An 8-inch stringer on the hanging wall side of the main vein, says Manager J. H. Elise, mills \$50 per ton. The ore of the main vein is in red granite, and is 30 feet wide; average value \$6 per ton.

The President mill is in operation on ore from a 4-foot vein with an average value of \$5.

Little Cripple Creek (Arrastra creek) is 3 miles from Placitas and 2½ miles from Hassayampa creek.

A. Ross, superintendent the President G. M. Co., and C. McKenzie have handed some of their holdings to Eastern men.

Superintendent Treadwell, the George A. Treadwell M. Co., near Jerome, says he will resume sinking the shaft on the Brookshire claim. They are shipping ore from this claim to their smelter at Mayer. A diamond drill will be put to work on the Cliff and Brookshire groups.

Manager G. W. Hull says he will put twenty more men at work on the ore bodies in the Hull mine cut by the Dillon tunnel, near Jerome.

O. L. Geer, of Martinez, says he will build a 50-stamp mill for his mines next month.

President F. Jager, the Model G. M. Co., says the company will spend \$100,000 for machinery, and in development of the mines. The capacity of their mill at McCabe will be increased.

The Verde King has men at work near Jerome sinking shaft.

CALIFORNIA.

AMADOR COUNTY.

Connection has been made on the 2625-foot level between the north and east shafts at the Kennedy mine, near Jackson, by an upraise from the west drift from the east shaft. The headplates for the hoist at the east shaft are in position.

At the Bay State, north of Plymouth, they are sinking the shaft 300 feet deeper from the 800-foot level.

The shaft at the Onelda mine, near Jackson, is being sunk below the 2000-foot level and is down 2075 feet.

The Cherokee Gold Dredging Co. is operating a dredger on the Mokelumne river.

Superintendent C. R. Downs of the Bunker Hill M. Co., north of Amador City, says a 20-stamp mill will be built. The 1400 level has been driven 150 feet on ore which averages 6 feet in width and will mill \$10 per ton. The vein in the 800-foot level has been exposed for several hundred feet. A station is being cut at the 1200 level, and, if development on this level warrants, the mill will be increased to forty stamps.

Work was resumed this week in the Centennial mine, near Drytown, after being idle eighteen months. L. Gross is superintendent.

The Amador Phoenix Co., near Jackson, is negotiating with the owners of the property for an extension of the bond.

An 8x10 double hoisting engine is being set up at the Edinburgh G. M. Co.'s shaft, near Jackson. The double-compartment shaft will be timbered to the tunnel level by the time the hoist is completed, when sinking will be resumed to the 500 level.

Manager Horn of the Horn mine, near Defender, will resume operations next week.

A dump has been sunk in the Shenandoah mine at Plymouth below the 1000-foot level, and drifting begun on the 8-foot ledge. Though the upper levels were dry, water has been found at the 1000-foot level.

It is reported that the Gowanus mine, east of Indian creek, owned by E. C. Brown of Plymouth, will resume.

Sutherland Bros. have their shaft on the Ochre lead, east of Plymouth, down 60 feet.

E. S. Potter has sold a one-fourth in-

terest in the Plymouth Rock mine, on the east bank of Indian creek, north of Plymouth.

It is reported the Zeila mine, near Jackson, will resume March 1.

CALAVERAS COUNTY.

The Royal Con. Co., Ltd., J. C. Kemp van Ee, superintendent, at Hodson, are building a 120-stamp mill in addition to the forty stamps now in operation. They are installing a hoist and an electric trolley line to haul the rock from the mine to the rock crushers and the mill, 1500 feet. Four cars will be used, having a capacity of five tons each. The hoist will be operated by compressed air, the compressor being driven by electric power already installed. The mill is on the crest of a bill, the batteries from sixty stamps running to each slope. Between these is the ore bin, with a capacity of 3000 tons, and the rock breakers. It will require 800 H. P., which will be furnished by the Stanislaus Light & Power Co. and Standard Electric Co.

Rich gravel is reported being hydraulicked at the Old Stiff mine, at Balaklava hill, south of Vallecito.

The Angels Record says Superintendent Langford of the Melones M. Co., at Melones, will put in a cylindrical ball mill to regrid the sulphides for cyaniding.

South ½ mile from the Royal mine, at Hodson, the Wilbur-Womble mine has at work twenty-five men. This company has a 6-stamp triple discharge mill and is putting in nine more stamps of the same type. The shaft is down 300 feet. Electric power is being substituted. E. A. Braddock is superintendent.

The Nelson M. Co. turned the water in their ditch last week and the giant is in operation at the mine near Calaveritas.

E. C. Rigney is putting in the flumes of the O'Neil creek ditch. The Eagle M. Co., operating the Treat claim near Cave City, has shut down on account of scarcity of water. Dixon & Edmunds are washing tailings on the Gunter mine at Washington Ranch.

Below Murphys the Lucky Jack, owned by Richmond, Mitchler & Ober, is being worked by tunnel. Adjoining this is the Tenderfoot mine, owned and operated by Richmond & Shepherd, who are erecting a water wheel.

The Queen mine, owned by Shaw Bros. of San Domingo, has been bonded to Eastern men.

At Douglas Flat the Forty nine M. Co. are sinking a three-compartment shaft. J. M. Evans is superintendent.

It is reported that operations will be resumed on the Manitou gravel mines at Vallecito.

CONTRA COSTA COUNTY.

The Contra Costa Oil Co. will drill a well on their land, 8 miles from Antioch, and one-quarter of a mile from the first well.

EL DORADO COUNTY.

There are twenty men employed at the Golden Gate mine, near Placerville.

The Whim mine at Fairplay has suspended work till spring. Superintendent J. J. Leventon, the Ellen Taylor mine, reports having struck a bed of pay gravel.

President Drury of the Golden Gate M. Co. says they will put in an air compressor and power drills at the mine near Placerville.

N. H. Burger, representing Eastern men, has bought the placer ground of W. P. Frick and G. W. Mauk, near Grizzly Flat. The mines were formerly hydraulicked, but the new management is running a tunnel to tap the channel and will work by the drift method hereafter.

GLENN COUNTY.

The well of the Washington-California Oil Co. at Fruto will be put down 2300 feet.

HUMBOLDT COUNTY.

G. Henderson, of Oakland, Cal., is interesting capital in the establishment of an electric plant on Klamath river, to develop 5000 H. P. The proposed plant will cost \$500,000 and the electric power will be distributed to mines on the Klamath and also taken to Eureka and other towns in that part of the State.

KERN COUNTY.

(Special Correspondence).—The Breadwinner G. M. Co., recently organized in Los Angeles, Cal., has secured the Old Cowboy mine, near Caliente, Amalie district. A mill will be built of forty tons capacity which will later be increased to 100 tons. It will be an electro-chemical process, which is said to work these ores economically. It is reported that 30,000 tons of pay ore is in sight.

The Gold Peak M. Co. at Amalie have several properties upon which work has been started. C. D. Porter of San Francisco, Cal., is in charge. The principal work has been done on the Red Rover

tunnel, which is in 400 feet. High-grade ore has been shipped at an expense of over \$30. Some of this ore ran as high as \$300 to the ton.

The Mines Ex. & Dev. Co., with offices in Los Angeles, Cal., are developing a group of twelve mines in this county and one at Placerville, Cal., running \$100 per ton.

Callente, Jan. 27.

It is reported the Kern River Oil Co. will sink more wells, and 1½-inch casing will be used in one.—The Eastern Con. Oil Co., which has six wells in the Kern river oil fields, has decided to put down four more.—The Shamrock well is flowing. The daily production for the past month has been 600 barrels.—The St. Paul & Sunset Oil Co., near the Queen wells, has finished its first well.

The Mountain Boy Oil Co. will resume operations in the Midway district.

Shipments from the McKittrick field are averaging fifteen cars daily, and more would be sent out if more cars were obtainable. The Sedalia and California, in the McKittrick field, has three completed wells pumping, and is at work on two more.

The King Refining Co., on the Alladin property in Kern river district, is setting up its stills.

The directors of the Old Glory Oil Co. have filed a petition in the Superior Court at Bakersfield for permission to change the name of the corporation to Old Glory G. M. Co., as there is an Arizona corporation of the same name doing business in this State.

S. J. Edginton, superintendent of the Del Rey Oil Co., near Bakersfield, is putting in a 7½-inch pipe line, from the company's property to the railroad. The company is cleaning out its wells and will begin pumping. Other wells will be drilled.

The Alta Oil Co. is down 700 feet in its well northwest of McKittrick.

LOS ANGELES COUNTY.

(Special Correspondence).—The After Gold M. Co. are doing development work on their mines in the San Gabriel canyon, above Azusa. Thirteen placer claims and twenty-three lode claims have been consolidated. The Lillian claim has a ledge 60 feet in width, free milling.

G. M. Cummings reports locating a placer claim in the upper San Gabriel canyon, yielding 16 cents to the pan.

Los Angeles, Jan. 26.

The Central Oil Co. at Whittier has put two more wells on the pump. No. 13 has been deepened, getting 120 feet more oil sand.

NEVADA COUNTY.

The Reddik M. Co. has sold its 10-stamp mill to the Oustomah M. Co., who will move it to their Pennsylvania mine, north of Nevada City. F. P. Williams is superintendent.

PLACER COUNTY.

The owners of the Pine Hill mine, 14 miles east from Auburn, have completed their 10-stamp mill, air compressor and steam plant. The main shaft is 180 feet deep, with a 400-foot crosscut, and they are breasting a 15-foot ledge of ore which assays \$10.

SAN BERNARDINO COUNTY.

(Special Correspondence).—The Federal G. M. Co., organized by C. H. Thompson, L. C. Gilliam and others, have secured the A. G. Campbell properties at Vanderhilt, in the eastern part of this county, consisting of seventeen claims, fifteen of which are patented. Twenty-five men are employed on development. Three hoists have been repaired, the 10-stamp mill being in good condition. The ore shoot on the 200-foot level shows a length of 205 feet, averaging 7 feet 8 inches in width, and 11 feet at its widest part, the ore assaying an average of \$12 per ton gold.

The Gold Bronze mine, owned by J. M. Hall and others, adjoining the Gold Bar mine of the Federal G. M. Co. at Vanderhilt, was working forty men, but a strike is on. Before the troubles regular shipments of bullion were made. It is reported that an ore shoot 4 feet wide was found in new workings.

Manvel, Jan. 26.

SAN MATEO COUNTY.

Frick & Parker are still drilling their well in the Tunitas. The Guiberson well is down 1200 feet.

Mahoney & Youle have the well of the San Mateo Oil Co. near La Honda cleaned and drilling resumed, being down 1200 feet.

SHASTA COUNTY.

It is reported that the storm in the early part of the week damaged the smelting plant at De Lamar to the extent of \$3000.

An air compressor and drills, to be driven by electricity, will be installed on

the Afterthought group, near Bellavista.

E. C. Christiansen, superintendent of the Gold Dollar group of mines in the Mule-town district, says preparations are being made to install a 10-stamp mill and concentrating plant on Clear creek.

The strike of the smelter men and miners at Keswick and Iron Mountain, that for four months has been in force, is at an end. At a recent conference between Manager Wright of the Mountain Copper Co. and Manager Lewis of the strike committee, it was agreed that the representatives of the Western Federation of Miners would declare the strike off and the men go to work, the company to post a notice that the company would not discriminate between union and non-union men. The notice posted is as follows: "Notice to Employees.—The Mountain Copper Co. has not and will not discriminate against any man because of his affiliation with labor unions. As soon as the company is assured of the maintenance of peaceable and orderly conditions in its neighborhood, it will resume its operations as rapidly and on as large a scale as other conditions will permit, and will entertain any man's application for employment without regard to his membership in any union. In taking on men, all other things being equal, it will prefer those whose skill has been proven by long service in its employment, and those who, being married, have families and homes in the neighborhood, and who would be, consequently, the most seriously injured both in respect to capital and income by failing to obtain employment at Keswick. Under no circumstances will the company employ any man who has engaged in unlawful violence toward its property or its employees."

Work will also be resumed on the Cow Creek power plant by the Northern California Power Co. The Texas mine will start up and small mines east of the river are making preparations to resume work. C. Raymond one day last week took \$200 from a placer claim he is working on Rock creek, 4 miles north of Redding.

C. J. Hammond has sold to J. D. Hammond and W. F. Aram for \$10,000 the Crown Point and Midnight quartz claims in Centerville mining district, near Redding, says the Searchlight.

Superintendent H. C. Woodrow of the Texas mine, near Whitehouse, says operations are resumed and ore is being shipped to the smelter at Keswick.

SISKIYOU COUNTY.

The compressor at the Keen & Co. quartz mine at Callahans is in operation and quartz is being broken for their cyanide plant.

A. C. Brokaw has an air compressor run by water power in operation at his quartz claim at Hull gulch, Quartz valley.

D. McCook has been running his quartz mill at the forks of Humbug on quartz from the Punch Creek mine, but the roads are in bad condition for hauling more from the mine.

The Michigan company working the Barton mine at Buckeye Bar, Klamath river, has resumed.

Garner, Quigley & Eastlick have resumed at their hydraulic mine at Oro Fino, using a 500-foot head of water.

TRINITY COUNTY.

At the Headlight mine Superintendent Fletcher has nineteen men at work.

The Integral quicksilver mine at Integral, ½ mile from Cinnabar, has twenty-five men at work. Two furnaces are in operation. The shaft is down 400 feet. F. Mahan is superintendent.

At the Cinnabar mine two men are working on the dump ore.

Superintendent H. Wilson of the Chloride-Bailey mine, near Dedrick, has 100 men at work. This company also owns the Jenny Lind and Maple mines, which it is preparing to work. Work has begun on a gravity tramway 2½ miles in length from the Jenny Lind and Maple to the new mill. This tramway will be equipped with twenty cars and have a capacity of fifty tons per day. It will also be used in transporting timber and supplies to the mines. Ore from the Chloride-Bailey is being transported to the mill by a wire tramway carrying 200 buckets, having a capacity of seventy-five tons per day. On this property is an ore body 4 feet wide on the bottom, with seven stopes running east and west from the lower levels. Last week \$17,000 in bullion, the result of four weeks' run, was shipped. Thirty stamps are dropping and twenty more will be added in the spring.

The Nevada and California quartz mines, 2 miles above Trinity Center, have been bonded to H. Hume for \$20,000. This property shows a ledge 12 feet wide which assays \$6 per ton. There are 600 feet of tunnel on the property.

A. Belli, owner of the Grutil quartz mine at the mouth of Coffee creek, says he has 200 feet of tunnel, with two parallel ledges, one 10 feet and the other 12

feet wide, with 100 feet of backs, and that the ore mills \$5 per ton free gold. The tailings are being saved for reduction.

Ruggles & Son, owners of the Nugget quartz mine on Coffee creek, have their 5-stamp mill dropping.

M. W. Collins, an owner in the Texas Jack mine on South Fork of Indian creek, says they are running on the ore body in the lower tunnel and the ledge is getting larger. The mill is in operation on \$30 ore.

Superintendent G. Lowden, the Three Peaks mine on Coffee Creek near Carrville, says ten stamps will be added to the mill this spring.

Manager W. B. Gester, the Bully Cboop mine, near Ono, Shasta county, has sixty men at work and ten stamps dropping in the mill, crushing sixty tons of gold-quartz daily.

TUOLUMNE COUNTY.

(Special Correspondence).—The water company claims the condition of snow on the range insures water for a long run this season.

At the Woodside mine, near Columbia, they are breasting gravel from a channel recently struck, which they will wash when the ditch is completed. Surveys have been made for a shaft on the north end of this property to develop the channel discovered on the Ranch mine, adjoining the Richards mine. Superintendent Muir has a few men on development work and taking out gravel. At the Ranch mine a bolting plant will be put up, a pipe line laid from Davies hill and a 75-ton washer installed, says Superintendent Stanford.

The Horseshoe Bend mine is working on their ditch and will resume work at their shaft next month. W. L. Holmes, managing owner the Altadena—John Royal mines, bonded the Royal claim in Experimental gulch this week. The property has a vein of low-grade quartz, though a \$40,000 pocket was taken out some years ago. The Mountain Lily mill is running on high-grade rock, and Lessees St. Clair & Woodruff are developing a claim near the Densmore mine.

Columbia, Jan. 23.

(Special Correspondence).—Wm. L. Holmes of Detroit, Mich., is here looking over his properties—the John Royal mine, near Columbia, and the Altadena mine, 4½ miles southeast of Columbia, on Yankee bill. Ten-stamp mills are under construction at these properties; that at the Altadena will begin operations in two weeks. A new hoist is also being put in at each of the properties. The vein on the John Royal mine is 8 feet wide, averaging \$10 per ton. Mr. Holmes will remain here for some months. W. G. Phipps is superintendent.

Columbia, Jan. 25.

Superintendent C. L. Uren the Eagle-Shawmut mine, near Chinese Camp, says a compressor will be added to their plant next month.

A 2-stamp prospect mill will be erected on the Fleming mine near Jamestown, owned by P. B. Smith.

Articles of Incorporation of the Horseshoe Bend M. Co. have been filed in Sonora. Principal place of business, Portland, Me.; capital stock, \$1,500,000; W. H. Gulliver, G. W. Gallison, W. W. Dresser, E. S. Taylor and W. B. Libby, directors.

At the Confidence mine, at Confidence, N. Carmichael, manager and superintendent, has twenty stamps dropping, crushing three tons per stamp. The mill has been remodeled, doing away with the concentrators. After amalgamation, hydraulic sizers are used and the pulp cyanided. The slimes are passed through filter presses.

Lack of water has suspended operations at the Star mine, on Rose creek, near Columbia.

The shaft at the Dutch mine, at Quartz, is down 1500 feet and sinking continues.

The ditch at the Grizzly mine, near Carters, has been cleaned out and the mill overhauled. A shoot of ore has been struck on the 900-foot level.

The Scott-Dow M. Co. (Black Oak), at Soulsbyville, has forty stamps dropping on ore from the 1200-foot level, and ninety-five men are at work. The ore is crushed through a 60-mesh screen, one ton per stamp being the output. C. S. Dow is superintendent of the mill and cyanide plant; W. G. Scott is superintendent of mine.

Superintendent W. L. Turner of the Rawhide M. Co., near Jamestown, has forty stamps dropping in the Rawhide mill and sixty at the App, with 225 men at work. The concentrates from the App mill are bailed to the Rawhide chlorination works.

J. H. Gilmore, superintendent of the Mt. Jefferson, has a 5 H. P. engine and a pump in operation in Groveland creek supplying water for the hoist and mill. Ore is being taken from the 300 and 400 levels and twenty stamps are dropping.

Daily shipments of sulphides are made, and the shafts and drifts have been retimbered.

The shaft on the Mountain Belle, near Soulsbyville, has been retimbered and machinery, including an air compressor, will be put in.

The roller mill in operation at the Sunnyside, near Arrastraville, will be replaced by a 10-stamp mill.

Superintendent Bower of the Mountain King says the road is completed to the property from the Keltz road, 1½ mile, saving 7 miles travel, via Confidence.

H. Ditts has bought a one-fourth interest in the Golden Ribbon mine, 2 miles west of the Buchanan.

The Piedmont G. M. Co. has bought the Sweeney quartz mine at Quartz mountain.

G. G. Grant of Carters has bought a group of placer claims on Jawbone ridge, near Jawbone creek, 10 miles east of Carters.

L. H. Laughlin of Quartz Mountain has bought a one-half interest in the Cibola claim, ½ mile distant from Stent.

The Manzanita G. M. Co. of South Dakota has bought the Mayflower and Extension, Red Haw, Lena Belle, Iron Cloud and Young America, together with the millsite, mill and improvements, 1 mile southwest of Carters.

COLORADO.

BOULDER COUNTY.

Pumping is resumed on the Republic oil well near Boulder.

At the Denver tunnel of the Denver T. & M. Co., near Wall Street, an air compressor and drills will be installed.

The United States Gold Co. has incorporated at Eldora. The company owns 300 acres of mineral ground southeast of the Con. Copper Co.'s holdings. They will drive a tunnel to cut their three veins in a distance of 1200 feet at a depth of 1000 feet. J. F. Rowell is manager.

CLEAR CREEK COUNTY.

Shipments made from the Mandota, near Silver Plume, last week included thirty-five tons of lead concentrates from the mill and twenty-five tons of ore from the mine, says Manager Old.

The Newhouse tunnel, near Idaho Springs, will be driven ahead to reach the Saratoga mine, says Manager Hanchett. It will have to be driven 1500 feet from the present heading, which is now in 3 miles. The Saratoga mine needs such connection, both for mining and drainage. The Old Town mine in Russell gulch will be reached either through the Newhouse drift or on the Saratoga vein.

T. S. O'Neil has bought the Allen mill on Chicago creek, near Idaho Springs, and is refitting it to handle custom ores by concentration, the mill being equipped with jigs, tables and stamps.

The Pacific M. Co., developing the Pacific and other lodes in Bridal Veil gulch, on Republican mountain, near Georgetown, says Manager Hartsborn, are in 345 feet on the Pacific lode, showing galena. They will put in a concentrating and power plant, to be run by water, and machine drills will be used.

The Key West M. Co. of Denver is developing the Key West and McKinney lodes on Leavenworth mountain, near Georgetown. There are two shafts on this vein, each 60 feet deep. Superintendent Murray is driving on the McKinney and crosscutting from this drift to the Key West.

The Monarch tunnel near Idaho Springs resumed driving last week.—It is reported the Big Chief M. & M. Co. will sink the main shaft another 200 feet and run levels, before taking out ore. The group consists of seventeen claims which adjoin the Lexington and Little Richard, up Soda creek.

The Yankee Con. M., M. & T. Co. of Denver has decided to lease some of their properties at Yankee.

CUSTER COUNTY.

A 300-ton mill will be built by the Terrible G. M. Co., operating the Terrible mine, near Iles, says Manager Brooks. The ore is lead carbonate.

EL PASO COUNTY.

The Oil Creek G. M. Co. has begun development of the group which it owns north of Cascade.

FREMONT COUNTY.

M. McNamara, of Coal Creek, says he has leased 360 acres of his land to the Standard Oil Co. on a 10% royalty, and drilling will begin.

C. Meyer and S. A. Van Buskirk, of Canon City, say they have opened up a ledge of black syenite, suitable for building and ornamental uses, near Cotopaxi. They have eighty acres of land covering the deposit. They will put up a plant in Canon City to polish the stone.

H. J. Hall and D. S. Hall have opened

up an ore shoot near the head of Smith gulch in Hardscrabble canyon, near Florence, which assays \$5 in gold, with some silver. They have located five claims on the vein.

A hoist will be built on the Gold Wonder mine, near Florence, and the shaft sunk to 300 feet.

The Fremont coal mine, near Rockvale, operated by the Colorado F. & I. Co., has been equipped with an electric lighting plant. Electric drills are used.

The Keystone Oil Co., near Florence, will drill another well.

GILPIN COUNTY.

The Cleveland M. Co. has bought portions of the Spur Daisy group of fourteen claims in the Eureka & Quartz Valley district for \$5000. The same parties are interested in the Bon Ton, adjoining the Spur Daisy, where they have installed machinery. J. Brohl is superintendent.

Central City parties are working the Ingoberg mine, on the north slope of Winnebago hill, and have the shaft down 310 feet. They are drifting from the 300-foot level and are making shipments to the Black Hawk mills.

The Deadwood placer claim, on South Boulder creek, near Rollinsville, was transferred by warranty deed by P. Rohling et al. to T. H. Potter and J. E. Lightbourn last week. This property is on the line of the Moffat road.

The shipments of smelting ores and concentrates from the mines around Central City for the first twelve days of January amounted to 131 cars, or 2620 tons. The ore was shipped to the smelters at Denver, Argo and Golden.

Manager Ballantyne, the Straub mine on Gunnell hill, near Central City, says their plant of machinery will be enlarged. The shaft is down 300 feet.

The Brooklyn group of mines (the Cashier, Republic Gregory and other patented claims), south of Central City, are being operated by the Brooklyn G. M. & M. Co., with R. St. J. Cleary of Denver as manager, and J. Faulkner superintendent of underground workings. The shaft is down 600 feet and crosscuts begun from the bottom of the same, both north and south. These crosscuts will open up five parallel veins, one of which is the extension of the Flisk-Cook vein and another is the extension of the O'Neill-Gregory lode. The Brooklyn Co. also own the stamp mill on North Clear creek.

The New National T. M. Co. will put in a 16 H. P. gasoline plant on the Horsehoe mine, east of Black Hawk. Chicago men are interested. The shaft is down 185 feet and will go deeper. J. Brohl is superintendent.

At the Barnes mine of the Horseshoe M. Co., on Quartz hill, the shaft is down 740 feet, says Superintendent N. H. Scheuer, and drifting has begun. The drift to the west is in 60 feet. They are working in the 600-foot stopes and running a crosscut to the north from the west 400-foot level. Lessees are stopping in the 400 level. Shipments have begun.

Idaho Springs parties have a lease and bond on the Golden Cloud group in Russell district, at the head of Virginia canyon, and will operate as the Golden Cloud M. Co. The shaft is down 300 feet and the lessees will sink 300 feet more.

The Central City Call says a local company is working the West Whiting mine on Gunnell hill under lease and making regular shipments from the 300 east level of fifteen to twenty cords per month of milling ore. S. Laner is in charge.

The Waltham mine near Russell Gulch will install a cyanide plant.

The Helen G. M. & T. Co., operating on the north side of Colorado hill, in the Pine district, near Central City, has a group of claims which will be developed by a tunnel, says Superintendent J. C. Coltrin, and machinery will be put in. The Moffat road will pass within a mile of the mine.

HINSDALE COUNTY.

Superintendent C. Forberg is driving the Double Standard tunnel near Lake City. — J. Cochrane, H. Barrett and J. R. Paterson have a bond and lease on the Lone Star group of claims on Henson creek, 1 mile from Lake City. The Lone Star is across Henson creek from the Pelican.

JEFFERSON COUNTY.

At Leyden, on the Moffat railroad, 10 miles northwest of Arvada, the Leyden Coal Co. are sinking a shaft to 660 feet, at which point it is expected to cut the vein. A spur is being built from the main line of the railroad to the mine.

LAKE COUNTY.

Minium (red lead) is reported in the Progressive M. Co. mine at Leadville. With it is associated silver chloride. The ore was found in the west drift of the Cady shaft.

The Crown Point, on Iron hill, Leadville, is being operated by J. D. Murphy

and M. Starne in the upper levels, where there is a body of iron ore. — The Virginious ground, running from Fryer hill across the gulch to the Progressive, is being worked by R. B. Estey. A shaft is started to cut the Progressive shoot. — The Resurrection mill started up last week and is treating 650 tons of ore daily.

The cyanide mill at the Ballard, on Brece hill, Leadville, is in operation, treating ore from the dump. At the Penn twenty-five tons a day are going out. — The Corona, in California gulch, is shipping thirty tons a day of lead ore, with silver values, which net the lessees \$30 a ton. The principal work is in drifting and stoping.

The Matchless mine, Fryer Hill, Leadville, has resumed under lease to D. D. Sullivan & Co. Work for the present is confined to the upper levels, where there is a body of iron ore. — The shaft of the Chrysolite resumed last week under lease to J. C. Hume & Co., and is shipping ore. — Hanifen & Reynolds have put a plant of machinery on the Ulster-Newton, and connections are being run to the Louisville. Milling ore is being taken out of the latter, and by spring the shaft will be unwatered and the sulphide bodies at the 1000-foot level worked.

Colorado Springs men have incorporated the Eleventh Hour M. & M. Co. The company has seven claims in Granite district on the Lake county side — the Eleventh Hour, Crater, Regina, Shady, Club, Last Chance and Coyote. The ore is part free milling and part smelting grade. R. L. Holland, A. K. Lanyon, J. Cromwell, W. R. Barnes and L. H. Skinner are the officers.

The Fortune mine, owned and operated by J. McNeese, has opened up a body of ore that averages \$40 per ton.

The Keystone M. Co., operating the Rex group, near Leadville, will put in a heavier pumping plant and unwater their lowest workings.

MESA COUNTY.

The Home and the Curtis oil companies of Debeque are drilling.

SAN JUAN COUNTY.

The shaft of the North Star mine on Sultan mountain, near Silverton, is being unwatered.

The Bluebell M. Co., owning the Hudson and American Belle mines at Red mountain, near Eureka, has resumed on the former and is drifting from the fourth level.

The Evening M. Co., owning the Evening Star mines in Mastodon gulch, near Silverton, has been reorganized. M. T. Jones of Chicago, Ill., is manager, says the Silverton Standard. — The Lackawanna mine on Kendall mountain, bonded by the Four Metals Co., is being opened up. — The North Star (Sultan mountain) shaft has been unwatered, using a 250-gallon balling tank.

SAN MIGUEL COUNTY.

Twenty stamps will be added to the Alta mill in Turkey basin, near Telluride, says Manager A. C. Koch.

The Copper Basin M. Co. is developing its group of eleven claims 2 miles from Placerville.

Superintendent J. H. Litchfield, the Double Eagle G. M. Co., has men on development work on the Double Eagle group of claims in Bridal Veil basin, near Telluride. The company expects to build a mill near Blue lake.

SUMMIT COUNTY.

Manager C. A. Finding has miners at work in the Iron Mask tunnel, near Breckenridge, retimbering, with the intention of running the tunnel another 700 feet to connect with the shaft. The tunnel is in 1300 feet.

Work has begun on the 800-foot tunnel of the Gold Bell M. Co. on the west slope of Mount Baldy, near Breckenridge. The principal ore body is a quartzite ledge, the continuation of the ledge on which the Golden Edge group and stamp mill are located. The tunnel will crosscut several lode claims owned by the company and be driven through the auriferous quartzite to the lime contact where carbonate ore carrying values in gold and silver is expected. A. Kemper is manager.

The Lightburn 7x7 tunnel of the Gold Run, near Breckenridge, is in 1420 feet and a branch from the main tunnel is being driven. The work is being done to develop fifty lode claims near the head of the gulch and will be driven for 3000 feet. Light and air are being supplied by electricity. — The Carbonate lode on Mount Baldy, operated by Risley, Moon & Horn, is shipping ten tons per month of a silver-lead ore that carries good values. The pay streak is 12 inches wide and in the trachyte. A tunnel will be driven to cut the vein from 200 to 300 feet deeper than the present workings.

The Mountain Pride mine on Mount Baldy, at the head of Illinois gulch, near Breckenridge, continues its regular out-

put of 100 tons per month of silver-lead ore and concentrates. — At the Cashier, in Brown's gulch section, the mill's capacity has been increased 200 tons per day of ore from the 80-foot ledge of gold and silver-bearing quartz.

TELLER COUNTY.

The Last Dollar and the Blue Bird mine on Bull hill, at Cripple Creek, have resumed.

Manager Walsh, the Addie Co. on Mineral hill, Cripple Creek, says he will sink to 1000 feet.

The Rocky Mountain L. Co., operating on the south end of the Deadwood claim, near Cripple Creek, made a shipment of thirty tons smelting grade ore last week.

The Des Moines Co. has granted a lease to J. T. Brown on its two claims, the Mud Hen and Bob Tail, on Raven hill, Cripple Creek.

Lessee Hammond has begun operations on the Colorado City claim of the Amazon M. Co., near the Sitting Bull, Cripple Creek district.

The Addie C. shaft on Mineral hill, Cripple Creek, will be sunk to the 1000-foot point, says Manager J. R. Walsh. A steam plant and a four-drill air compressor will be installed.

A plant of machinery will be installed at the Pueblo & Cripple Creek Railway tunnel, near Cripple Creek, in the breast of the tunnel, in 7700 feet. Pyrites are being found assaying \$8. A drift has been run 200 feet to connect with the shaft of the Callie, 400 feet deep. Stopping will be done from this level to the surface.

The Arequa mill, near Cripple Creek, has been bought by the Colorado Ore R. Co. for \$67,376. The property included the mill, the millsite, the townsite and all other rights.

It is reported the Victor mine will resume, with J. Canning of Aspen as manager.

J. F. Hadley has bought a half interest in the Henry Adney claim, near the C. K. & N. and Old Gold mines, Cripple Creek. The shaft will be sunk to the 400-foot level and laterals driven after the 200-foot station is cut.

Superintendent J. Barr has begun operations on the Pinto claim of the Free Colnago Co. on Bull hill, Cripple Creek, under lease to H. Shell of Altman.

The Cripple Creek Enterprise G. M. Co. has resumed sinking in the Hanley shaft at Cripple Creek.

Machine drills will be put in at the Lincoln mine, near Gillett.

Superintendent H. M. Risley is opening up the Frank Burk group on Iron mountain, 2½ miles southwest of Cripple Creek.

Lessees Rogers & Mullins, operating through the Burns shaft of the Acacia on Bull hill, Cripple Creek, shipped a car of two-ounce gold ore this week. Lessees McKinsey & Read, operating on the south end, will sink. There are seven sets of lessees on the Acacia.

The Stratton ground of 650 acres will be leased, says Manager W. G. Rice of the Stratton Cripple Creek M. & D. Co., in blocks 300 feet square. Blocks may contain a portion of one claim, and part of another, as the whole will be surveyed and platted regardless of claim lines.

The Iowa Co., working on the south slope of Trall mountain, 3 miles from Victor, has a shaft down for 75 feet and is using electric drills.

The Ophir mine, on Raven hill, Cripple Creek, is producing 180 tons of smelting grade ore each month. The work of driving the tunnel to connect with the shaft is going ahead.

The Eleanor & Dorothy G. M. Co., owning claims adjoining the Sedan and Sunshine claims, will let a contract for driving a crosscut west from the Dorothy & Eleanor shaft to cut the Sedan vein. It is believed a crosscut 25 feet in length will cut the vein. The shaft is down 150 feet.

Lessees on the Anaconda Co. ground on Gold hill, Cripple Creek, are producing 600 tons a month of \$30 ore. Thirty-five sets of lessees are working, of whom fifteen are shipping.

Three new leases were granted on the Pharmacist, at Cripple Creek, last week. Floyd & Carter have the ground from the sixth to the fourth level, Whitlock & Speers a block on No. 5 and Nesbitt & Co. on the Water Witch shaft.

The lessees operating the Blanche, on Bull hill, at Cripple Creek, last week closed a shipment of two carloads of smelting grade ore. — The production of the Tornado mine, on Raven hill, has been increased to a carload a day.

Operations are resumed on the Rose Maud by Lessees Nelson and Honning and a steam plant and hoist are being installed. The shaft is down 125 feet.

Three sets of lessees are working on the Mint property, on Gold hill, Cripple Creek district.

The shaft on the Addie C., on Mineral hill, Cripple Creek district, will be sunk to the 1000-foot point. The shaft is 458 feet deep, with two levels started to ex-

plore the formation at 300 feet and at 400 feet. The 300-foot level is being driven south of the shaft. A steam plant and compressor will be installed.

The Blue Flag Co., operating the Blue Flag claim on Raven hill, Cripple Creek, is retimbering the shaft. Machinery will be put in.

Morris, Johnson & Darnell have a two years' lease on the north end of the Ramona mine, on Bull hill, Cripple Creek, and will prospect to find if the extension of the War Eagle shoot passes into that ground. In trenching they have opened a vein on surface which yields free gold in panning.

Lessees Schoonover & Miles, working on the Little Valeria, on Gold hill, Cripple Creek, which adjoins the Gold Bond, sent out their initial shipment last week, which assayed \$20 gold. — Wilson & Co., operating a lease on the south end of Goldfield, have cut a vein at a depth of 60 feet which assays \$10 gold. — Lessee Reiten, operating on a block of the Bonanza King, on the northwest slope of Gold hill, has opened an ore chute 2 feet wide in a crosscut run for 40 feet north of the shaft at the 80-foot point.

IDAHO.

BLAINE COUNTY.

The Amalgamated Gold Dredging Co. of South Dakota has bought of J. E. Bloom and H. L. Childs their interests in the Nineteenth, Euclid, Euclid No. 2, Lupita and Century placer claims, near Soldier, aggregating 660 acres on the South Boise river, north of its junction with the Big Smoky river; also the Childs placer claim of 20 acres adjoining the above.

At the Tip Top mine, near Halley, Superintendent Lusk is drifting on the 1100-foot level.

T. C. Woodbridge and T. M. Smeltzer have located the Woodbridge, Woodbridge No. 2, Smeltzer, Smeltzer No. 2 and Chas. McGrade lode claims in Lava Creek mining district, near Halley.

BOISE COUNTY.

The tunnel on the Maud Marsh, on Miller mountain, near Idaho City, has been run 188 feet this winter. A crosscut was run from the 50 foot point and another at 100 feet. Both were run 45 feet in ore assaying \$6 a ton, says G. A. Williams.

H. Daly, working the Gentle Anna claim, one of the group near Idaho City bonded to V. Thorne, says a tunnel has been run 200 feet, and in ore except the first 40 feet. At 160 feet a crosscut was run 45 feet to the hanging wall, in ore that will run \$6 a ton. On the hanging wall a 3-foot shoot goes \$20. The depth at the face of the tunnel is 75 feet. A raise will be run to the upper works. A crosscut tunnel, run 200 feet, tapped a 7-foot ledge of \$15 ore in the Democrat. There has been opened a 5-foot ledge of ore at the depth of 100 feet in the John Henry. The Democrat is the north vein, with a dip of 60°; the Gentle Anna next, dipping at 30°; the John Henry the south vein, with a 45° dip. A shaft will be sunk 500 feet in the spring on the apex of the Anna, and at 500 feet will cut the Democrat. A 40-stamp mill will be put upon the properties next summer.

The Last Chance mine at Quartzburg closed down Jan. 12th because of too much water.

Woodmore & Youren have a contract to run a 200-foot tunnel on the Belshazzer mine, near Placerville, which is bonded to W. D. Southworth, of Placerville.

CUSTER COUNTY.

Manager W. McK. Flynn of the Snowstorm M. & M. Co. says they are developing their group of thirteen claims in the Seafarm mining district. The Snowstorm ledge runs 4982 feet through four of the claims, and carries values in lead, gold, silver and zinc.

IDAHO COUNTY.

B. J. Mack, secretary and manager the Rankin M. & M. Co., in Black Lake district, 16 miles from Pollock, reports construction work has begun on the mill and concentrator.

Manager F. Brown, the Jumbo mine of Buffalo Hump, says a concentrator, cyanide plant and twenty stamps will be added to the mill. The strike in the lower tunnel shows 12 feet of quartz, which assays \$10. The ore body in the upper tunnel is 9 feet wide and assays \$12 per ton.

D. Terwillinger, of Weiser, has bought the interests of his associates in the Snow Slide group of sixteen claims on Snow Slide creek, Thunder Mountain district. The claims are 8 miles from the Dewey mine, between it and Profile creek. A ledge 50 feet wide, running through the group that averages \$5 per ton has been uncovered.

W. D. Lovejoy, M. A. Daily, J. P. Gray and W. D. Manley will work the Short

Bar placers on the Little Salmon river, near Pollock, under lease and bond.

H. H. Hunter, operating on Big creek, in Thunder Mountain district, 35 miles from the Dewey mine, has 18 men at work.

The American Eagle, at Elk City, last week shipped two gold bars worth \$3300 as a result of a 10-day run, says C. K. Merriam of the company operating the mine under bond. There are seventeen claims in the American Eagle group.

KOOTENAI COUNTY.

The Panhandle Smelter Co. has bought 400 acres of ground at Sandpoint, where it will build a smelter next summer.

OWYHEE COUNTY.

Superintendent Prisk of the Sinker tunnel, near Silver City, says the tunnel company will not resume operations until they can get lumber for a power plant, which will be in April.

LOUISIANA.

CALCASIEU COUNTY.

The Virginia Oil Co. has incorporated to operate in the Welsh field in the Conover subdivision, on which S. H. Keoughan is putting down a well; G. Conover, J. F. Miller, W. B. Conover, F. E. Bliss, R. W. Mills, M. Yable, C. M. Tinney and J. F. Miller. W. B. Conover is manager.

MICHIGAN.

INGHAM COUNTY.

A Chilean mill is in operation at the Quincy stamp mill at Mason, regrinding the coarse gravel as it comes from the beads. The Osceola is putting in a similar mill.

HOUGHTON COUNTY.

The management of the Atlantic is operating thirty-three drills and sending to the mill 1375 tons of ore daily. A shaft is sinking to the eighth level. B shaft is down to the twentieth level and D shaft is sinking to the thirty-fourth level.

The water power of the Victoria, near Houghton, is to be developed on a larger scale than at first planned, in order to furnish power for the Michigan mine and mill as well.

It is reported that the output from the three principal mines of the South Range group this year is expected to reach 40,000,000 pounds of refined copper, and this from twelve shafts. The output of the Calumet & Hecla is on a basis of 80,000,000 pounds of copper per annum, operating through twenty shafts.

The stamp mill of the Phoenix is inclosed and will be in operation by March 1st. They will run the single head on day shifts only for 1903, as not enough stopes have been opened underground to supply the head with rock for double shift, says the News. Cutting down and retimbering shafts and opening the incline shaft at the St. Clair through to surface have precluded opening as many stopes as desired. The Phoenix is expected to return thirty pounds ingot copper per ton of rock stamped. A portion of the product will be mass and barrel copper.

MONTANA.

FLATHEAD COUNTY.

D. P. Bowers, manager the Snowshoe mine, near Libby, owned by the Rustler M. Co. of Spokane, Wash., says a strike of 2 feet of galena has been made, and the company will spend \$50,000 during the coming summer in enlarging the mill and putting in power.

Finch & Campbell, of Spokane, will resume operations on their group of claims at Silvanite next month.

GRANITE COUNTY.

The Gladstone M. Co., L. U. Loomis superintendent, operating on Gold creek, near Phillipsburg, has temporarily closed down.

A. C. Beggs, who bought the Hughes interests on Little Gold creek, near Phillipsburg, will build a reduction plant.

JEFFERSON COUNTY.

W. Dodge, B. Kilburn & Co., developing a group of claims in Basin creek district, 2 miles north of Basin, will install a hoisting plant.

PARK COUNTY.

J. A. Murray, of Butte, is working his mine at Jardine and will drive a tunnel 2500 feet to cut the ledges exposed on the surface.

SILVER BOW COUNTY.

(Special Correspondence).—At the annual meeting of the Montana Standard M. Co. P. T. Davis was elected president, L. Wotrich vice-president, F. T. Britton treasurer, W. H. Lindsay secretary; trustees—A. N. Yoder, B. Calkins, R. W. Charlton.

Butte, Jan. 15.

NEVADA.

ELKO COUNTY.

The Leonard Taylor M. Co. of Albany, N. Y., has bought the property of the Bull Run M. Co., at Bull Run, for \$150,000. M. E. Hopkins of Boise, Idaho, is manager.

At White Rock the Edgemont Co. is employing forty-five men and has its 20-stamp mill in operation. Thirty men are at work in the Curieux mine, and ten stamps dropping. The Riddle mine is reported bonded by Eastern men for \$100,000.

H. P. Taylor, manager and part owner the Murphy-Curieux mines at Bull Run, near Tonopah, says the 10-stamp mill will be enlarged to twenty stamps and cyanide works added. The cost of these and other necessary work will bring the total to \$200,000.

ESMERALDA COUNTY.

The Nevada Chief M. Co. has taken up its bond on the Rockland mine near Pinegrove.

The Southern Nevada G. M. Co. has bought several properties around Red Mountain and Silver Peak. Development work will be continued and a reduction plant built at Silver Peak.

HUMBOLDT COUNTY.

Returns from two carloads of ore shipped from the Arizona mine of the California-Nevada Co., at Unionville, are said to have been so satisfactory that a mill will be built.

The sulphur deposit near Humboldt House will be worked to ascertain its depth and value.

There are twenty-three men at work in the Glasgow & Western Co.'s Adelaide mine, at Golconda, and pay rock is piling up on the dumps.

LINCOLN COUNTY.

(Special Correspondence).—The Nevada-Keystone M. Co., whose mines, mill and cyanide plant are in the Yellow Pine mining district, near Sandy, has twelve claims, forty acres of land in their millsite, two Huntingtons, and a 30 ton cyanide plant. Before incorporating the owners spent \$35,000 developing new ore bodies, as the mines were supposed to have been worked out after producing over \$380,000. The company was incorporated in May, 1902, and has taken out \$10,000 every month. The deepest workings are 700 feet, the ore assaying \$154 gold per ton, and is free milling—85% saved by amalgamation. Ore bins are building at the mines. A road from the mine to the mill is being constructed, and excavating for a new hoist is in progress. On the 300 level a raise has been started to connect with the new incline. Samples in a drift on the 300 level from a streak 18 inches wide gave \$132 gold to the ton. An average of fifty-four tons of ore milled gave \$50 per ton. A small streak in drifting from the winze in the 200 level returned \$212. Another body of ore has been struck on the Barefoot claim.

Sandy, Jan. 24.

(Special Correspondence).—Searchlight district was formed four years ago. It is in the southern part of the county and is reached by way of Goff's, on the Santa Fe R. R. The district is 30 miles long by 15 miles wide. There are three groups of properties producing in the aggregate \$100,000 per month. The ore is gold and is free milling. The average values run about \$15 to the ton. Besides these properties owned by the Southern Nevada M. Co., the Duplex Co. and the Quartette M. Co., each owning their own mills, the Rambler group, owned by Maud & Coleman Co., and the mines of the Wilson M. Co. of Edinburgh, Scotland, are being worked. Other properties are being developed. The town of Searchlight has a population of 600 people.

Searchlight, Jan. 23.

G. E. Otis of Redlands, Cal., has bought three-quarters interest in the Commonwealth group of mines, near Searchlight.

C. Alvord is developing his claims at El Dorado. On the McKinley he has a 40-foot shaft, and the ore is being shipped by wagon 50 miles to Manvel, Cal., thence by rail to San Francisco. On the Skylark are two tunnels, 145 feet long, cutting the ledge at 200 feet depth, showing a 14-inch shoot of \$25 ore.

At a depth of 77 feet the shaft of the Cyrus Noble near Searchlight is in ore which runs \$10 in gold, says Superintendent W. H. Bainbridge.

Turquoise is reported found in the country rock at Bamberger's De Lamar mines. The Toltec M. Co. turquoise mines are in the same district.

LYON COUNTY.

Manager F. Leonard, at Sutro, says operations have begun on the tunnel to unwater the south end of the Comstock by the Gold Canyon Extension Co. This tunnel will begin at the end of the Sutro at

the Alta shaft and extend to the Dayton shaft, 8300 feet. It will run on the vein and open up the mine at an average depth of 1000 feet. The greatest depth now worked is 250 feet. The success of this extension will lead to the extension of a lateral 5000 feet to American Flat. A short distance beyond the Alta shaft the Comstock lode divides, one branch going to Silver City and the other to American Flat. The Gold Canyon will install a mill and acquires the right to work the mines if the owners do not do so themselves. The Con. Cal. & Virginia is pumping from the 2150-foot level, and it is proposed with electric pumps to drain the 2500-foot level. This is 750 feet below the tunnel, and with the surface water provided for, it will be possible to go to that depth in the mines of Silver City below the tunnel level.

NYE COUNTY.

At the Montana-Tonopah mine, on Odie mountain, near Butler, the vein struck at 450 feet depth is being opened up. At 462 feet the ledge is 6 feet wide and dips south at an angle of 67°, says the Miner. On the hanging wall is a shoot of sulphide ore 15 inches wide carrying ruby and horn silver and gold. Superintendent G. F. Badgett has twenty men at work.

The North Star, near Butler, is putting up a hoist to sink the shaft, now down 540 feet, to 1500 feet, says Manager Ish.

The Mizpah Extension Co. has their main shaft down 625 feet and more. The crosscut at the 485-foot level is in 105 feet and in the ledge cut above the 400 in the shaft.

A 13-foot ledge has been cut in the shaft of the Desert Queen, near Butler, carrying values of \$15 per ton. At 609 feet a station is being cut.

In Hananah district L. L. Patrick has begun work with ten men on the Pinto group of fifteen claims adjoining the Newhouse property. Four veins have been located on the Pinto group and surrounding croppings show values in gold and silver.

At the Templar group of three claims and a fraction near Butler, adjoining the California-Tonopah on the west, Superintendent L. L. Patrick has let a contract to sink 200 feet.

In the Fraction, near Butler, connection was made last week on the 400 level between shafts Nos. 1 and 2, and men are at work in No. 1. In this crosscut the last 132 feet were run in twenty-one days.

A strike of ore, running high in gold, silver and lead, was made in the 165-foot level of the Ray & O'Brien last week in Tonopah.

STOREY COUNTY.

Drill hole No. 3 on the Brunswick lode, near Virginia City, is down 550 feet. The bottom is in porphyry and requires no casing.

WASHOE COUNTY.

A discovery of coal is reported near Verdi.

At the Wedekind and Blackburn mine, in Antelope valley, the engine for the mine is in place and the mill in operation. The Lee Bros. have bonded their three claims for \$80,000, and received \$4000 as first payment.

WHITE PINE COUNTY.

The hoist on the Copper Flat mine at Ely is in operation.

NEW MEXICO.

BERNALILLO COUNTY.

W. D. Kemp has sold a half interest in the Manhattan copper mine, in the Sandia mountains, 14 miles east of Bernalillo, to F. E. Sturges of Albuquerque.

CHAVES COUNTY.

W. A. McIvers, manager New Mexico Oil & Dev. Co., operating near Roswell, says their first well is down 300 feet, and, from the appearance of the formations, they expect to get oil at from 900 to 1200 feet.

COLFAX COUNTY.

Croasdale & Love, contractors, are building derricks for the drilling plant of the New Mexico Oil & Gas Co. on McKom tract, near Raton.

GRANT COUNTY.

The property of the Lena M. & C. Co., near Lordsburg, was sold at trustee's sale last week to the American Con. C. Co., a New Mexico corporation with offices at Columbus, Ohio. The mill has a capacity of 150 tons per day.

GUADALUPE COUNTY.

The New Mexican says that a plant for neutralizing the alkali in water has been erected by the Rock Island railway at Santa Rosa, consisting of one large tank and four smaller ones. Water is pumped into first tank and solutions of lime and soda added, precipitating alkali. The water is then run into the four settling tanks.

LINCOLN COUNTY.

O. H. Stanley, vice-president and manager the American Con. M. Co., operating in the Rio Hondo district, near Hondo, says a reduction plant of 100 tons daily capacity will be built. The Fraser Mountain Co., south of the American, have in operation a smelter and concentrating plant of 120 tons daily capacity, but will double the capacity and install a larger electric power plant.

OTERO COUNTY.

Edmiston Bros. of Alamogordo have a drilling outfit of 1000 feet capacity, and will sink the first well for oil 15 miles southwest of Alamogordo and north of Dog canyon. They will also drill in San Andreas region.

SANTA FE COUNTY.

A new placer mining district is being opened up near Golden, in the southern part of the county, and fifty men are at work with dry washers, blanket tossing, etc. As high as \$20 per day has been cleaned up by one man.

NEW YORK.

CORTLAND COUNTY.

At Marathon, a gold-bearing vein is reported and assays are being made.

OREGON.

BAKER COUNTY.

Superintendent Barrett says the crosscut being driven on the Grand Union, near Sumpter, is expected to tap the Concord vein next week, giving a depth of 600 feet. The tunnel is in 690 feet. A mill will be built next summer.

Manager Bellman says the California aerial tram is in operation, near Sumpter, making the third aerial tram operating in the district. It has 5760 feet of steel cable, 1/4-inch diameter, making a traction distance of 2800 feet. The buckets carry 250 pounds each, and will deliver ten tons per hour.

Superintendent G. J. Barrett says operations will be resumed on the Big Four group near Sumpter, and drifting and crosscutting begun.

The Old Arrastra G. M. Co., C. S. Miller of Sumpter superintendent, will put ventilating machinery in their tunnel being driven on the Weigman claim. A 20-stamp mill and concentrating plant will be built next summer.

The Cracker-Klondike G. M. & D. Co. is incorporated, T. J. Marcum, S. O. Coolidge, A. O. Kessel, M. W. Beck with, C. H. Chance, to engage in general mining business, with headquarters at Bourne.

Four veins have been cut by the crosscut tunnel being driven with power drills to tap the ore bodies on the Oregon Monarch ledges near the Red Boy, near Sumpter.

At the Ross Gulch mine, near Geiser, the shaft is down 200 feet and a crosscut started. Hauling ore to the Empire mill is resumed.

GRANT COUNTY.

Manager W. H. Chambers, at the Big Producer group, near Alamo, expects to cut the Boston Boy ledge this week. There are eleven claims in the group.

Manager J. P. McGuigan says the lower tunnel of the Alamo Con. M. & M. Co., near Alamo, has cut the vein at 1200 feet and a vertical depth of 510 feet. Assays show \$10 gold. The company have two water rights, millsite, and placer ground for dumping and building purposes, and will build a mill this spring.

The Daines G. M. & M. Co. has bought the Golden Gate group of quartz claims in Quartz gulch, Alamo, for \$15,000.

JACKSON COUNTY.

J. O. Jillson will resume operations at the Jillson & Roberts mine next week. It is reported the La Flesh mine has been bonded to Portland parties.

The Bowden M. Co. is reported to have bought the Humason mill and water right, near Gold Hill.

The quartz mines south of Myrtle creek, near Jacksonville, are shipping ore. A 13-ton lot from the Little Chieftain mine returned \$700 net. The Continental, adjoining, was sold last week by G. W. Crews to W. B. Stewart for \$20,000.

Superintendent A. T. Lungren of the Cook & Green copper mine, in the Siskiyou mountains, near the State line, owned by Cooper, Hamilton & Co., says the ore shows 5% copper and \$6 gold per ton.

MALHEUR COUNTY.

The 20-stamp mill on the Black Eagle mine, near Malheur City, is in operation, says Manager Meikle.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The Cleopatra Co., on Squaw creek, near Deadwood, is in 180 feet in the drift

from the bottom of the shaft along the quartzite, and is expected to cut the ore body at 200 feet.

D. N. Helzer, secretary and treasurer of the Spearfish G. M. & R. Co., operating at Cyanide, gives the following statement of the mill operations for December: Total net tonnage, 5065.59; average value per ton, tank filling, \$5.105; average value per ton, tank tailings, \$1.351; net indicated extraction, per ton, \$3.854; total indicated extraction, \$19,123.84. As the last bar of bullion ran \$7000, the total recovery for December was \$22,000, of which possibly \$350 was from old slugs, leaving \$21,500 as the actual recovery, \$2521 above the indicated recovery. The value in the tailings has been reduced by 50 cents, showing a recovery of 83%. The values obtained from fourteen fillings of the tanks show an average of the ore produced of \$5.97 per ton.

Work is resumed by the Titanic Co. near Carbonate, 10 miles northwest of Deadwood, and an air compressor and pump will be put in. The company owns 1000 acres of land and will prospect the quartzite. The shaft is 250 feet deep.

PENNINGTON COUNTY.

A strike is reported made in the Maloney Blue Lead copper mine, 5 miles from Hill City, of ore showing native copper and sulphides, with values in gold and nickel. The main ledge is 100 feet wide, opened by a tunnel at a depth of 700 feet. Drifts have been run both ways on the vein from the main tunnel, the strike having been made in the north drift.

TEXAS.

HARDIN COUNTY.

Contractor Davie has struck oil in the Davey well, at Sourlake, at 500 feet.

UTAH.

BEAVER COUNTY.

Each group of the properties of the Majestic M. Co. at Lewisville, below Milford, is to be electrically equipped, says Manager W. A. Parish. The ore opened up in the Old Hickory shows an average of 8.8% copper with gold and silver and the "waste dump" 2.9% copper with the screenings averaging 3.75%. A sampling of the iron ore body shows an average of 2.7% copper. The Marloweaux interest in the Gomer and Contact mines has been sold to the Majestic Co.

The plans for the concentrator to be built on the Cactus group, near Frisco, have been changed, and a plant of 1200 tons will be built instead of less. G. K. Fischer is superintendent.

J. Henshaw, secretary of the Majestic M. Co. at Milford, gives details of a strike in Oklahoma ground in the Old Hickory group. The development in the Oklahoma consists of a vein 15 feet wide of copper, gold and silver-bearing ore which assays an average of \$25.

The Montreal group of mines out of Milford are sold to A. B. Lewis of Salt Lake City for \$200,000.

The Imperial M. Co. are putting up a gasoline hoist, bunk houses, blacksmith shop, etc., at the Comet mine, near Frisco.

Manager Ehrenberg of the Frisco mine at Frisco, says the output of the mine for January would be 2000 tons of concentrates. The company has 250 men at work and 550 tons of ore per day are being taken out. The greatest depth in the mine is 2000 feet from the apex of the vein. The shaft will be sunk another 200 feet.

Shipments of iron ore from the Cave mine, near Milford, will be increased to a carload a day.

The Horn Silver mill at Frisco will resume.

DAVIS COUNTY.

Articles of incorporation were filed last week by the Texas M. Co., which will operate the Texas, Olympia, Iowa, Oregon, Alabama, Indiana and Galena Dip Nos. 1 and 2 claims, near Bountiful.

JUAB COUNTY.

A body of 30% copper ore was uncovered on the 300-foot level of the Star Con. at Tintic last week.

The Monster M. Co., of Dutch mountain, in Deep Creek region, near Fish Springs, adjoining the Garrison M. Co., has bought the Uncle Sam claim for \$8000. This ground is valuable to the company, as it affords access to a tunnel site, through which their ore bodies can be opened up and which ore wagons can reach with little expense. J. A. Edwards, developing a property 2 miles east of the Gold Hill, on the edge of the desert, says he is sinking on a 4-foot ledge that carries \$7 in gold and a percentage of blisuth.—The Christmas Co. has let a contract to sink its shaft another 100 feet, it being down 90 feet.

The Centennial Eureka of Tintic will sink the shaft to 500 feet below the collar,

giving a maximum of 2850 feet below the mineral-bearing zone.

The shipping of argentiferous iron ores from the mines of the Swansea M. Co. at Silver City to the furnaces of the Bingham Co. is suspended temporarily, says Manager Geddes.

S. F. Kershaw has taken a contract for driving the tunnel on the Elgin M. Co. group, near Diamond, another 200 feet. Work is being done through the Old Susan tunnel, now in 800 feet.

SALT LAKE COUNTY.

At the Old Evergreen in Big Cottonwood district, Manager H. J. McMillan says that at 550 feet the fissure on which they have been driving has opened up to 2 feet, and carries copper pyrite associated with red oxide, and carbonates showing 4% copper, \$4 gold and eight ounces silver.

From the Highland Boy's furnaces at Bingham, for the week ending Jan. 17 was forwarded to the Eastern refinery 302,000 pounds of copper, gold and silver-bearing bullion, with the plant running on 500 tons of ore daily, and from the United States S. Co. went 181,362 pounds of pig copper, carrying gold and silver, with three of its five furnaces in commission.

Connection was made last week through the Miners' Dream tunnel with the Brooklyn mine of the Bingham Con. In making the connection a body of ore 31 feet wide was opened up, running 40% lead and showing values in gold and silver. The Bingham management are taking ore from the Brooklyn and this week expect to strike the body of ore in the Antelope claim.

The Kennebec M. Co. of Salt Lake City, W. J. Craig manager, will install an electric power plant in Big Cottonwood canyon, and machine drills will be put in their mines near Alta.

The York M. Co., operating at Bingham, lost its hoisting plant by fire last week and much of the machinery was damaged. W. C. Orem is manager.

SEVIER COUNTY.

The Gold Cup M. Co. has incorporated at Richfield, B. T. Ashby, A. K. Hansen, J. E. Hepler, H. N. Hayes, A. M. Hepler, to operate a group of ten claims adjoining the B. W. & H. on the north. Development work will begin next month.

Manager H. J. Gottfredson, the Gold Mountain D. Co. in Deer Creek canyon, near Richfield, says the tunnel being driven to cut the Jumbo vein is in 200 feet, and in another 100 feet it is expected to cut the lode at a depth of 250 feet. The ore carries gold and silver, being a cyanide proposition, and a plant will be installed as soon as sufficient ore has been blocked out.

SUMMIT COUNTY.

S. Spiro, manager the Little Bell of Park City, reports the shaft down 500 feet and crosscutting begun at that level.

The Nalldriver hoist, near Park City, is completed and the gallows-frame is being built.

Superintendent J. H. Keetley of the King Extension, near Park City, says they will consolidate with the Bogan M. Co. and resume development of both properties.

TOOELE COUNTY.

A mill is to be built at the Stockton mine of the Stockton G. M. Co., near Stockton, says Manager J. J. Trenman.

The Garrison G. M. & M. Co. has bought the Uncle Sam mine on Dutch mountain, Clifton district, near Ibapah, for \$6000.

WASHINGTON COUNTY.

Manager G. Snyder, the Dixie mines, near St. George, says the smelter will be completed next week.

WASHINGTON.

FERRY COUNTY.

At the Black Tail mine, near Republic, a drift is being run on an ore shoot on the intermediate level, and shipments made.

The Zala M. mine in Republic has suspended operations because the Granby smelter cannot treat its ores, due to lack of coke.

OKANOGAN COUNTY.

M. A. Smalley & Sons have put up a horse whim on the Oregon mine, near Chesaw, and resumed sinking the shaft.

STEVENS COUNTY.

Superintendent J. R. Lee of the Eagle mine at Chewelah says the ledge has been opened up, showing 21 feet in width on the lower level and carrying silver, lead and peacock copper.

The Minoreca mine on Fifteen Mile creek, near Ryan, under Superintendent L. L. Tower, will put in a diamond drill to prospect their ore body. He has 500 tons of ore on the dump, which will be shipped.

Only three of the six furnaces of the Le Roi Co. smelters at Northport are in operation because of shortage in coke supply.

WYOMING.

CARBON COUNTY.

The Osceola and Copper Belt properties near Dillon are bonded for sixty days. The Osceola has been bonded to W. G. Emerson and the Copper Belt to C. Fishback—each for \$200,000. The Copper Belt Co. is driving a tunnel on a vein found by J. Morrison and is intended to develop all of the company's properties. A crosscut will be driven 500 feet north to cut the main Rudelheh lead.

The North American Copper Co., having drained the Ferris-Haggerty group near Dillon by tapping with a tunnel, will sink 500 feet deeper, says Manager W. Bunce.

FREMONT COUNTY.

A new copper and gold camp is being opened up at Papville at the head of Bridger creek, 21 miles from Lost Cabin and 21 miles from Thermopolls Hot Springs. There are thirty-five claims in operation. The Copper Glance and the Lone Tree are being developed by J. E. Dain of Caspar, Wyo.

FOREIGN.

BRITISH COLUMBIA.

Superintendent P. White of the Wilson mine, near Ymir, says a partial clean-up from a test run of the mill gave a gold bar weighing eight pounds. They are saving 75% of the values by amalgamation, and the tailings from the concentrates assay \$1.50 per ton from ore that runs \$12. The ore running \$40 is shipped.

On the Dumas group, near Ymir, the lower tunnel is in 250 feet and in ore. Another 50 feet will bring the face to a point 100 feet below the pay streak of galena ore exposed at the mouth of No. 1 tunnel.

J. E. Edwards, owning three-sixteenths interest in the Blue Jay mine, in Skylark camp, has a bond and lease on the remainder for \$10,000. The Blue Jay is 1½ mile from the city, on the same ledge with the Old Ironsides and Knob Hill mines.

The Montreal & Boston C. Co. will put in a copper converter at its smelter at Boundary Falls.

J. Nelson, F. Williams and E. Johnson will work the Rob Roy group of mines, consisting of the Rob Roy and Copper Belt Fraction, in Isadore canyon, near Fort Steele. The quartz carries copper and gold.

The Caribon Creek D. Syndicate has bought a one-third interest in the Fidelity group of six claims—the Abercombe group—adjoining the Mountain Lion south property on American hill, near Ferguson.

CANADA.

QUEBEC.

C. K. Milbourne, of Montreal, says a copper producing plant will be installed at Shawingan Falls, 90 miles from Montreal, if the co-operation of firms interested in the copper trade cannot be secured to have the plant built at Montreal.

MEXICO.

CHIHUAHUA.

The shaft of the Shamrock mine of the Boston & Chihuahua M. Co., at Terrazas camp, last week cut a body of ore, says Manager Ariett, assaying in lead and silver equal to \$20 in gold values. The shaft is being continued and a drift run from the 200-foot level.

The next annual meeting of the International Miners' Association will be held at Chihuahua.

Manager W. J. Parker of the Urique G. M. Co. is having machinery for its 100-ton mill at Urique packed in from Minaca. The machinery was made in sections for this purpose. It is expected to be in operation by June.

It is reported the Eureka M. Co. struck a body of ore in the Santa Juliana mine, in the Santa Eulalia district, last week, that runs fifty ounces silver and 25% lead. The strike was made with the diamond drill from a drift on the 125-foot level.

SONORA.

Six miles northeast of La Dura, on the Yaqui river, J. McCallum and J. L. Shepard will begin development of their copper mine, the Creston de Cobre.

C. Anderson has bonded the Beaverich copper mine, near the Yaqui, north of Sahuaripa, and will begin development.

The Yaqui S. & R. Co. will build a smelter at their mines near Ures.

Phelps, Dodge & Co. are reported to have a lease and bond on the mines of the Indiana-Sonora Copper Co., on the Cobre Grande lode in the Cananea district, for \$1,000,000.

W. E. Defty has bought a one-fourth interest in the Yaqui mine, adjoining the Martha, near Altar.

Manager J. C. Underwood of the Yerkes M. & M. Co., at Camp Yerkes, near Altar, says construction work has begun on their mill.

PERSONAL.

R. J. WALTERS of Denver, Colo., is in Kingman, Ariz.

T. L. ODDIE of Tonopah, Nev., is in San Francisco, Cal.

T. B. SCOTT has returned to Chicago from Chloride, Ariz.

F. ISH is manager of the North Star M. Co., Butler, Nev.

E. R. WOAKES, Nelson, B. C., has gone to London, Eng.

M. P. BOSS has returned to San Francisco, Cal., from Mayer, Ariz.

MANAGER FELT of the Model M. Co., near Prescott, Ariz., has gone East.

LEON M. HALL has returned to San Francisco, Cal., from Tonopah, Nev.

W. T. SPENCER, owner of copper mines at Rainville, Utah, is in San Francisco.

D. M. WATTERS is superintendent of the Cracker-Oregon mines at Bourne, Or.

H. K. WHEELER, a Los Angeles mining engineer, is sojourning in San Francisco, Cal.

J. J. DALY of the Daly-Judge mine at Park City, Utah, has returned from the East.

C. R. TOWNSEND is superintendent of the Virginia mine in Greenhorn district, Oregon.

W. C. GREENE, president Greene Con. Copper Co., Cananea, Sonora, Mexico, is in New York.

W. L. WATTS has returned to Los Angeles, Cal., from Santa Barbara county, Cal., oil fields.

E. W. GIDDINGS of Colorado Springs, Colo., is president Isabella G. M. Co., at Cripple Creek, Colo.

MANAGER J. K. ROMIG of the Sanger mine near Baker City, Or., has returned from Milwaukee, Wis.

G. H. ROBINSON, manager of the Tintic M. & D. Co. of Tintic, Utah, went to Butte, Mont., last week.

B. BLANCHARD, superintendent of the Iron King mine, near Jerome, Ariz., has returned from the East.

F. H. OLIVER of Spokane, Wash., managing director Morrison mines, near Rossland, is in Rossland, B. C.

G. K. FISCHER is superintendent of construction at the concentrator of the Cactus mines at Frisco, Utah.

D. C. MONROE is superintendent of the Rowe mine of the New York & Arizona G. M. Co. at Walker, Ariz.

MANAGER M. J. TRUE of the Bluebird M. Co., near Dillon, Beaver county, Utah, has returned from the East.

T. M. YERKES, president Yerkes M. & M. Co., at Camp Yerkes, near Altar, Sonora, Mexico, is at the mine.

W. L. HOLMES, manager of the Altadena-John Royal mines, near Columbia, Cal., is in San Francisco, Cal.

MANAGER G. MOORE of the Sunshine M. Co. returned last week to Salt Lake City, Utah, from Kansas City, Mo.

L. L. MYERS, superintendent of the Malakoff mine at North Bloomfield, Cal., is in San Francisco, Cal., this week.

SUPERINTENDENT J. A. PORTER, Fair view mine, near Weaverville, Trinity county, Cal., is in San Francisco, Cal.

H. W. HOYT, vice-president The Ailes-Chalmers Co., Chicago, made a business trip to San Francisco, Cal., this week.

MANAGER L. T. WRIGHT of the Mountain Copper Co. returned last week to Keswick, Cal., from San Francisco, Cal.

R. E. OBER, superintendent of the Beatrice mine at Murphys, Calaveras county, Cal., has gone East on company business.

W. E. SHEPMAN, president Maple Creek M. Co., has returned to San Francisco, Cal., from their mines near Weaverville, Cal.

H. W. TURNER, superintendent Cherry Hill mine, Siskiyou county, Cal., has returned to the mine from San Francisco, Cal.

J. F. STULTZ of Hermosillo, Mexico, is at Campo Santo Nifo, Sonora, engaged on construction plans for the Yaqui Copper Co.

W. E. THORNE has left San Francisco, Cal., for Forty-Mile creek, Alaska, to assume the management of the Big Bend M. Co.'s property there.

R. K. NEAL, manager of Finch & Campbell's mines, returned to Kendall, Mont.,

last week from an extended trip through Washington and California.

A. MOORE, manager Newton Cement Works, is also superintendent Colorado Portland Cement Works, near Florence, Colo., vice T. B. Rennell, resigned.

T. B. RENNELL has resigned as superintendent of the mill of the Colorado Portland Cement Works, near Florence, Colo., and will go to Philadelphia, Pa.

T. MCGUIGAN is manager American Boy Mines in Slocan district, B. C., and the affairs of the mine will be conducted from Sandon, B. C., instead of Spokane, Wash.

HOMER WILSON AND F. R. CULBERTSON have returned to San Francisco, Cal., from the Chloride-Bailey mine, Trinity county, Cal., in which they are interested.

R. NICHOLS, general manager Great Boulder Perseverance mines and mills in West Australia, is at Bingham, Utah, examining the ore bodies of the Boston Con. Co.

MANAGER A. TRITTENBACH of the Dutch M. & M. Co. at Quartz, Tuolumne county, Cal., has returned from the annual meeting of the company in San Francisco, Cal.

W. G. SCOTT, part owner and superintendent Scott-Dow M. Co. (Black Oak mine), at Soulsville, Cal., is in Oakland, Cal. W. P. Scott, manager same company, is ill with pneumonia.

A. J. MCMILLAN is managing director of the Le Roi Co., whose mines are at Roseland, B. C., and smelters at Northport, Wash., and will make his permanent headquarters at Roseland.

P. BOUERY, superintendent of the La Grange Hydraulic M. Co., Weaverville, Trinity county, Cal., is in San Francisco, Cal., and will visit the southern part of the State before returning to the mine.

Commercial Paragraphs.

CHAS C. MOORE & CO., of San Francisco, have leased larger and better equipped offices and salesrooms in the Union Foundry Block, San Francisco, and about March 1st they will occupy their new quarters on N. E. cor. Mission and First streets.

IN addition to the Truax ore cars, the Glohe Iron Works of Stockton, Cal., make a specialty of power transmission appliances, boxes, hangers, couplings, shaftings, pulleys, floor stands. Complete catalogue and price list will be sent anywhere on request.

F. W. BRAUN & CO., of Los Angeles, Cal., who have recently purchased the business of John Taylor & Co., of San Francisco, Cal., the old established dealers in assayers' supplies, have moved their San Francisco branch to the new large building, Nos. 18 and 20 Spear St., San Francisco, Cal., one block from the ferry depot.

THE C. O. Bartlett & Snow Co. of Cleveland, Ohio, write that they have lately received orders for their grill four-compartment driers from the Bronson Portland Cement Co., Bronson, Mich.; Illinois Central Railroad Co., Chicago, Ill.; Colonial Construction Co., Hudson, N. Y.; and they are also erecting driers for the St. Louis Portland Cement Co., St. Louis, Mo.; Egyptian Portland Cement Co., Detroit, Mich., and have completed two driers for the Southwestern Portland Cement Co., White Cliffs, Ark.

Obituary.

A. E. NELSON, formerly head of the Nelson Business College of Memphis, Tenn., died at Somerville on the 16th inst. of consumption. Three years past he was superintendent of the Maravilla Copper Co.

D. N. STRADLEY, M. D., manager of the company building a smelter at Banner in San Diego county, Cal., died at San Diego on the 15th inst. from injuries, the result of being thrown from his carriage. Deceased was 53 years old, and leaves a wife and one son.

Catalogues Received.

Catalogue No. 14, second edition, issued by the Allis-Chalmers Co., Chicago, Ill., is a good treatise on chlorination, cyanide and lixiviation, and will be sent upon request to any address.

New Patents.

DEWEY, STRONG & CO'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR THE WEEK ENDING JANUARY 20, 1903.

718,809.—SPEAKING TUBE MOUTHPIECE—J. C. Bahr, S. F.
718,847.—LIFTING JACK—H. Dearhorn, Pescadero, Cal.
718,833.—BEET PLOW—W. H. Gilbert, Orange, Cal.
718,755.—FURNACE AIR HEATER—J. L. Giroux, Jerome, Ariz.
718,756.—STEAM GENERATOR—J. L. Giroux, Jerome, Ariz.
718,985.—WATER TOWER—H. H. Gorter, S. F.
718,781.—VENT FOR CASKS—J. G. F. Heiber, Spokane, Wash.
718,710.—BUCKLE—W. Houghton, Snohomish, Wash.
718,841.—BICYCLE HANDLE BAR—J. W. Leavitt, S. F.
718,853.—GOPHER TRAP—J. M. Merritt, Los Angeles, Cal.
718,819.—STAPLE—W. H. Morehouse, Wasco, Or.
718,559.—OIL BURNER—D. H. Mosteller, S. F.
718,728.—SMELTING FURNACE—Pettengill & Nicholson, Los Angeles, Cal.
718,739.—IRRIGATOR—E. E. Stende, Newcastle, Cal.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

AIR HEATERS FOR SMELTING FURNACES.—No. 718,755. Jan. 20, 1903. J. L. Giroux, Jerome, A. T. This invention consists of a series of vertically disposed pipes arranged to inclose the upper portion of the furnace through which the hot products of combustion pass, and from which pipes the air is led to the tuyeres, through which it is delivered into the lower part of the furnace proper. In conjunction with these vertical pipes a series of pipes extending transversely across the furnace above the vertical pipes is shown, into which transverse pipes the air is first transmitted and delivered from these pipes to pass through the vertical pipes and thence through the tuyere pipe or trunk, from which it is passed to the tuyeres. The invention is especially designed for use in connection with smelting and like furnaces.

STEAM GENERATING FURNACE.—No. 718,758. Jan. 20, 1903. J. L. Giroux, Jerome, A. T. This invention relates to a combination furnace and steam generator in which a crucible occupies the lower part of the furnace, and above this, in conjunction with suitably constructed water jackets, are arranged a series of vertically disposed water tubes surrounding and inclosed by sheets of steel, said tubes having their lower ends connected with a feed and supply pipe and the upper ends connected with a steam drum, into which the steam is collected. The rectangular water jackets are connected by upwardly extending corner jackets with the storage tank, into which the water is delivered and from which it is returned through suitable connections and delivered into the feed pipe which supplies the vertical tubes. This apparatus as constructed insures a more direct and better circulation of water through the pipes and steam drum than has apparatus of this class heretofore constructed.

MOUTHPIECE FOR SPEAKING TUBES.—No. 718,809. Jan. 20, 1903. J. C. Bahr, San Francisco, Cal. This invention relates to a mouthpiece for speaking tubes, and especially for such tubes as are used upon war and other ships or in other positions where they are exposed to the weather, and also where a large number of tubes are concentrated at one point. The object of the invention is to provide a protection and closure for the mouths of such tubes when not in use, an indicator, which is opened by the blast upon the whistle when one of the tubes is in use, and a means for opening the tube, so as to leave it entirely unimpeded for speaking purposes.

Latest Market Reports.

SAN FRANCISCO, Jan. 30, 1903.

METALS.

SILVER.—Per oz., Troy: London, 21 3/4 (standard ounce, 925 fine); New York, bar silver, 47 1/2c, refined (1000 fine); San Francisco, 47 1/2c; Mexican dollars, 38 1/2 @ 39c San Francisco, 37 1/2c New York.

COPPER.—New York: Standard, 11 1/2 1/4; Lake, 1 to 3 casks, 12 1/2 1/4; carload lots, 12 1/2 1/4; Electrolytic, 1 to 3 casks, 12 1/2 1/4; carload lots, 12 1/2 1/4; Casting, 1 to 3 casks, 12 1/2 1/4; carload lots, 11 1/2 1/4. San Francisco: \$14.00. Mill copper plates, \$17.00; bars, 18 @ 24c. London: \$54 12s 6d spot per ton.

Copper still shows an upward tendency. The Amalgamated Copper Co. and the United Metals Selling Co. are reported to have withdrawn from the Copper Producers' Association, but definite action has been postponed until February 17. Owing to the fact that some large producers have failed to make their monthly reports of production, and the suspicion that some companies have misstated their production, the obtaining of reliable figures is difficult, and as the stocks on hand bear an important relation to demand, and consequently price, a forecast of the market is only problematical.

LEAD.—New York, \$4.12 1/2; Salt Lake City, \$3.50; St. Louis, \$4.00; San Francisco \$4.50, carload lots; 4 1/2c 1000 to 4000 lbs.; pipe 5 1/2, sheet 6, bar 5 1/2; pig, \$4.75. London: £11 8s 9d per long ton = 2.49c per lb.

SPELTER.—New York, \$4.90; St.

Louis, \$4.50; London, £20 5s per ton; San Francisco, ton lots, 6 1/2c; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9 1/2c; Hallett's, 8 1/2c; San Francisco, 1000-lb. lots, 10c; 300 to 500 lbs., 11c; 100-lb. lots, 13 @ 15c.

TIN.—New York, pig, \$29.10 @ 29.40; San Francisco, ton lots, 31c; 500 lbs., 31c; 200 lbs., 31 1/2c; less, 31c; bar tin, 3 1/2, 35c @ 37 1/2c. London, £132 10s spot.

PLATINUM.—San Francisco, crude, \$18.00 @ 19c; New York, ingot, \$19.00 per Troy oz. Platinum ware, 75 @ 80c per gram.

QUICKSILVER.—New York, \$45.50 @ 46.50; large lots; London, £8 15s; San Francisco, local, \$45.50 @ 46.50; 7 1/2 lb.; Denver, \$49.50. Export, \$43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6 1/2c; extras, 17 1/2c; genuine, 35c; Eclipse, 37 1/2c.

ALUMINUM.—New York, No. 1, 99 1/2 pure ingots, 35c; No. 2, 90 1/2, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 19 1/2c; San Francisco, Plumbers', 100-lb. lots, 16 1/2c.

NICKEL.—New York, 50 @ 60c @ 70c; ton lots, 45 @ 48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$22.10; gray forge, \$20.50; San Francisco, bar, 3c @ 4c, 3 1/2c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$30.00 @ 31.00; open hearth billets, \$32.00 @ 33.00; San Francisco, bar, 7c to 12c per lb.

CHICAGO CURRENT QUOTATIONS.

Cast borings	10.25 @ 11.50
Turnings	14.00 @ 14.50

LUMBER.—(Retail): Pine, ordinary sizes, \$20.00 @ 22.00; extra sizes higher; redwood, \$22.00 @ 23.00; lath, 4 feet, \$4.25 @ 4.50; pickets, \$19.50; shingles, \$2.35 for No. 1 and \$2.00 for No. 2; shakes, \$13.50 for split and \$14.50 for sawed; rustic, \$26.00 @ 32.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, \$3.35; Cut, \$3.35; 10d to 16d, Wire, \$3.35; Cut, \$3.35; 8d, Wire, \$3.40; Cut, \$3.40; 6d and 7d, Wire, \$3.50; Cut, \$3.50; 4d and 5d, Wire, \$3.60; Cut, \$3.60; 3d, Wire, \$3.75; Cut, \$3.75; 2d, Wire, \$4.00; Cut, \$4.00. Special rates for carload lots.

GENERAL SUPPLIES.

POWDER.—F. O. B. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15 1/2c; less than one ton, 17 1/2c. No. 1*, 60% carload lots, 13 1/2c; less than one ton, 15 1/2c. No. 1** 50%, carload lots, 11 1/2c; less than one ton, 13 1/2c. No. 2, 40% carload lots, 10c; less than one ton, 12c. No. 2*, 35% carload lots, 9 1/2c; less than one ton, 11 1/2c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2 per keg.

CAPS.—3x, \$5.50 per 1000; 4x, \$6.50; 5x, \$8; Lion, \$9, in lots not less than 1000.

FUSE.—Triple tape, \$3.60 per 1000 feet; double tape, \$3.00; single tape, \$2.65;

Hemp, \$2.10; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10 1/2c @ set; 14 oz., 40s., 9 1/2c.

CHEMICALS.—Cyanide of potassium, 98%—99%, jobbing, 25 @ 26c @ lb.; carloads, 24 @ 24 1/2c; in 10-lb. tins, 35c; sulphuric acid, in carboys, 66% B, 2c @ lb.; soda ash, \$2.00 @ 100 lbs.; hyposulphite of soda, 2 1/2 @ 3c @ lb.; blue vitriol, 5 1/2 @ 6 1/2c @ lb.; borax, concentrated, 7 @ 8c @ lb.; chlorate of potash, 12 @ 13c; roll sulphur, 4 @ 6c; ground sulphur, 4 @ 6c; flour sulphur, French, 2 @ 3c; alum, \$2.00 @ 2.25; California refined, 2 @ 2 1/2c; nitric acid, in carboys, 8c @ lb.; caustic soda, in drums, 3 @ 4c @ lb.; Cal. s. soda, bbls., \$1.25 @ 1.50 @ 100 lbs.; sds., \$1.05; chloride of lime, spot, \$3.00 @ 4.00; nitrate of potash, in bbls, 8c; caustic potash, 10c in 40-lb. tins; sulphide of iron, 9c @ lb.; copper sulphate, 5 @ 7c.

CEMENT.—Germania, \$2.50 @ 2.75; K. & B. S., \$3.00; Hewmoor, \$2.90; Trowell, \$2.90; Portland, \$2.50 @ 2.75 per bbl.

LIME.—Santa Cruz, \$2.25; Roche Harbor, \$2.25 per bbl.

OILS.—Linseed, boiled, bbl., 56c; cs., 61c; raw, bbl., 54c; cs., 59c; lots of 5 bbls., 1c less; Lucol oil, boiled, bbl., 50c; cs., 55c; raw, bbl., 48c; cs., 53c. Kerosene—Pearl, per gal., 22 1/2c; Astral, 22 1/2c; Star, 22 1/2c; Extra Star, 25 1/2c; Eocene, 24 1/2c; Elaine, 27 1/2c; Water White, in bulk, 16c; Mineral Seal, iron bbls., 18c; wooden bbls., 21c; cs., 24c; Mineral Sperm, cs., 26 1/2c; Deodorized Stove Gasoline, bulk, 18 1/2c; do., cs., 25c; 86° Gasoline, bulk, 21c; do., cs., 27 1/2c; 63° Naphtha or Benzine, deodorized, in bulk, per gal., 16c; do., in cs., 22 1/2c; Lard Oil, No. 1 bbl., 95c; cs., \$1.00; Neatsfoot Oil, bbl., 70c; cs., 75c; No. 1 bbl., 55 @ 57 1/2c; cs., 57 1/2 @ 60c; Sperm, crude, 50 @ 60c; Natural White, 65c; Bleached do, 70c; Whale Oil, cs., 60 @ 55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6c; 1 ton and less than 5 tons, per lb., 6 1/2c; 500 lbs. and less than 1 ton, per lb., 6c; less than 500 lbs., per lb., 6 1/2c; in 25-lb. tin pails, 7c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, 7c per lb. above keg price. Dry Lead—in bbls., 1 ton and over, 6c; do. in kegs, 6 1/2c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Carbon, Eastern and foreign: Wallsend, \$6.50; Brynmor, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8; Cumberland, \$12; Cannel, \$9.00; Welsh Anthracite, \$11.50; Rock Springs, \$9.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13 in sacks; Sunnyside, \$8.50, long ton.

RED LEAD.—One ton and over at one purchase, per lb., 6c; 500 lbs. and less than 1 ton, per lb., 6 1/2c; less than 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8 @ 9c per lb.

BONE ASH.—Extra No. 1, 5 @ 6c per lb. No. 1, 4 @ 5c.

BORAX.—Concentrated, 7 @ 9c per lb.; powdered, 9 @ 12c; fused, 25 @ 30c.

BISMUTH.—Subnitrate, per lb., \$1.60.

BONE ASH.—4c @ lb.

BORAX.—Crystall, 7c; calcined, 25c.

COPPER.—Sulphate, 5 @ 7c.

MANGANESE.—(90% and over) 7 @ lb., \$1.25.

MOLYBDENUM.—25c. @ gramme; 1000 grammes—2 1/2 lbs.

CHROMIUM.—(90% and over) per lb., \$1.25.

MERCURY.—Bichloride, 7 @ lb., 90c.

PHOSPHORUS.—(American) 7 @ lb., \$1.00.

SILVER.—Chloride, 7 @ oz., 75c; nitrate, 55c.

URANIUM.—Oxide, 7 @ lb., \$3.50.

ZINC.—Metallic, chemically pure, 7 @ lb., 50c; dust, 7 @ lb., 10c; sulphate, 7 @ lb., .04c.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

WANTED.

1 belt driven Air Compressor for 40 h. p. engine.
2 Automatic Ore Feeders.
2 large Ore Buckets.
1 Dynamo, 75 light.
1 Rock Breaker.
1 double cylinder Hoist.
40 ft. 3/4" Cable.
Must be in st-class condition and cheap. Locate and describe fully O. H. MCCONUGHEY, 628 Montgomery St., San Francisco.

The Leasing System.

There is a tendency in some mining States, and more particularly in certain districts, for large mining concerns to absorb all or most of the properties in their immediate vicinity, in this way forming large combinations. Such propositions give employment

mating separate industries of a single class under one management.

There is another and entirely different method of operating properties, whereby possibly the greatest profit may be realized, and in which a diametrically opposite course is pursued. This is the leasing system as generally practiced and which is much in

exploited vigorously at one time, employment is given to a greater number of men, and costs are reduced to a basis as low as—if not lower than—those obtaining at the large consolidations, for the leasers have an incentive which does not actuate men working under the wage system. The leaser is working for himself, and on his effort depends his

The Zinc and Fluor Spar Mines of Kentucky. (See Page 87.)

to a great number of men both above and below ground, skilled and unskilled. A single individual, the general manager, directs the destinies of the proposition, aided by a corps of capable assistants. Costs are reduced to a minimum under careful management, and in this manner some low-grade properties may become profitable, which, when divided into individual concerns, each with a manager or superintendent and staff, and usually also with separate metallurgical plant, gave only mediocre results or possibly failed to pay at all. The profitable consolidation of these several properties under a single management illustrates the advantages of amalga-

vogue in Colorado. Instead of absorbing all the surrounding territory, single claims or groups of claims are subdivided into relatively small tracts and the several sections leased on a basis of percentage of output to individuals, associated or singly, or to corporations organized for the purpose of working properties under lease. There are many mines the output of which singly is too small to justify a mill, smelter or other reduction works, and these in the hands of leasers make a profitable production under the leasing system, impossible or at least unusual when operated by a single company or individual. By the leasing system the several portions of the mine are being

success, and he will usually see to it that there are no drones in his hive of industry. By this system no extravagance is permitted, high-salaried officers are dispensed with, everything is done in the most direct and economical manner, and there is no waste either of energy or material. Where a number of leasers operate separate blocks of adjoining ground a common expense is often shared by all, such as handling water, or cost of dead work for ventilation, etc. As a result the leasing system, as generally conducted, is prolific of satisfactory results, and it will compare favorably in methods and economy with those of some great concerns making records in mine enterprises.

MINING AND SCIENTIFIC PRESS.

ESTABLISHED 1860.

Published Every Saturday at 330 Market St., San Francisco, Cal.
TELEPHONE, DAVIS 771.

ANNUAL SUBSCRIPTION.

United States, Mexico and Canada.....\$3 00
All Other Countries in the Postal Union.....5 00

Entered at the San Francisco Postoffice as second-class mail matter.

SO far in 1903, even more frequently than in former years, come requests for articles on or information concerning some points in mining or metallurgical practice, such requested information having frequently been given in just the shape asked for in some recent issues. This fact illustrates the tendency to overlook or forget. It is further exemplified by the occasional receipt from a friend or admirer of a marked article in some contemporary, suggesting that that should naturally have appeared first in this journal, when as a matter of fact the article did so first appear herein, but so long ago that it had become common property and its worth having been tardily recognized by some less enterprising contemporary, it had been given place without credit to its original source. The subject is cited merely to suggest that it were well to follow the example of so many readers of the MINING AND SCIENTIFIC PRESS who file their copies for reference and have them bound at the end of each six months. In no way can a better or cheaper mining and metallurgical library be secured, and when some particular data are required on some important present point it is almost certain that reference to the index in the closing pages of some recent volume will give the very information wished. While on this subject it may be further said that the numerous requests for republication of articles cannot well be complied with. That would argue a poverty of resources and the vast amount of matter constantly pressing for attention would accumulate in even still greater degree. This last may answer the queries: "Why don't you write of the need of a cabinet department of mines and mining?" "Why not make present argument for repeal of the extralateral apex clause and amendment of the federal mining law?" Those things have been discussed herein, the reasons plainly set forth, and repetition would only weaken the argument. There are many other things that deserve discussion and it is not the province of a progressive journal to thresh over old straw.

The Strength of Materials in Mines.

Considerable careful study has been given the strength of materials by engineers and it has been reduced to an absolute science. In the construction of buildings, bridges and other structures above ground, where the atmospheric and other conditions are practically constant, and where the materials employed, whether wood, iron or steel, do not deteriorate to any marked extent during a long period of time, the theory of the "strength of materials" is of great value to the constructing engineer, but those in charge of planning and supervising such structures, if not technically educated, are more likely to employ an unnecessary amount of material than too little. This is often evidenced in the construction of large and expensive wooden headframes at mine shafts, where the main members of the frame are frequently so placed that they bear no direct relation to the strains the structure will have to withstand. True, the frame answers the purpose, and endures a decade or more, but one-half the cost in materials, and labor properly directed, would have provided a finer appearing frame, answering every requirement and having at the same time an abundant factor for safety.

The strength of materials is a subject which receives only passing consideration, however, by the "timber boss" of a mine, except relatively in a general way. If ground is known to be "heavy" he selects a larger timber than if it is known to be fairly good. He knows from experience that timbers will not perfectly sustain rocks or "ground," as he calls all kinds of rock, when it begins to "come." If he cannot quickly fill the excavation with waste rock and in that manner forestall the threatened cave, he must let it come, for if the danger be imminent no amount of timber he would have time to place would sustain the ground. A careful observer, but one inexperienced in mining, might reach the conclusion in passing through a mine that more judgment should be exercised in the selection and placing of timbers, particularly where he sees certain portions of the workings heavily reinforced by timbers recently placed. There are many cases, of course, where such a conclusion would be justified by the condition of things, but under ordinary circumstances such is not the case.

When the excavation is first made, timbers are or are not put in, as the condition of the ground may require. Or there may be a choice between heavy and medium-sized timbers. Supposing a timber to have been necessary at once. It is selected as above stated with reference to immediate necessity. The moment timber is taken into the mine it commences to deteriorate rapidly—some kinds much more so than others—in this respect differing from materials in structures on the surface. In a few months, or possibly weeks, the rocks through which the mine workings pass begin to settle. The air has penetrated them through fissures, cracks and pores; they become "heavy," and the timbers show signs of "weight" where the several members of a set come in contact, at the joints, or where they abut on the walls, and the lagging also gives warning of the threatened collapse. The miner notices this as quickly as a mariner notes the signs of an approaching storm, and watches it carefully from day to day. Often after a certain amount of pressure has made itself evident, it seems for the time to progress no further, and thereafter it may be many weeks or even months before this "piece of ground" is considered dangerous; when, if it is desirable to keep the workings open, the necessary steps are taken to prevent caving. This may be accomplished by re-timbering, decay having weakened the original timbers, or by reinforcing with additional timbers, to sustain the ground for a further period. If in a stope, filling should be, and usually is, resorted to. Some of the most disastrous caves in mining history have been due to neglect to promptly attend to this matter, and still the miners knew that the timbers would not long sustain the great weight resting upon them.

In addition to the weight of the rocks immediately adjacent to timber sets, the fact that the "ground" is in motion to a greater or less extent—depending somewhat upon the development of the mine on levels above and below—results in the weight and pressure being shifted from one direction to another. In fact,

the conditions are constantly changing and the miner is unable to figure upon the "strength of materials" with that nicety which comes within the range of practice of the constructing engineer, who calculates upon a set of conditions in which the factors are essentially constant.

The economies of the proposition also enter into the miner's calculations to a great extent. If he knows the work is not to be of permanent character he proceeds accordingly, and makes no unnecessary expense in uselessly heavy timbers, but meets the immediate necessities in a practical and usually satisfactory manner, wasting little time on theories which experience has taught him serve no useful purpose. In this respect the methods of the trained and practical mining engineer and those of the practical, though unscientific, miner differ little.

Powder Magazines in Mines.

The advisability of storing nitro powders in mine workings is brought prominently into notice by the introduction recently into the Utah Legislature of a bill prohibiting the storage of powder in the mines, presumably as result of the recent explosion in the Daly-West mine at Park City, in that State. The opinion of mining men is about evenly divided on the subject, some managers seeing no disadvantage or danger in the practice, others being of different opinion. The fact that large amounts of nitro powders are daily consumed in mines does not appear to be sufficient reason for storing it in large quantities in underground workings without taking the precautions necessary to avoid a disaster similar to that above mentioned.

The practice of keeping even so small a quantity of the dangerous explosive as even two or three boxes at shaft stations, or at any point along a main gangway, where men frequently pass, or at any point on the main line between the working faces and the means of exit, should be strictly prohibited, if necessary by legislation, as in such situations the powder is a constant menace to the lives of men employed. Nevertheless the construction of an underground magazine in a dry portion of the mine has been recommended, as it keeps the powder at uniform temperature, but it should be located on a level either practically abandoned or little used, and at a distance from the shaft or main adit. When this is done but one man on each shift should have access to the magazine, he to supply the several levels with powder by the box as needed. Under no circumstances should detonating caps be stored at the same place as the powder, whether in the magazine or at the priming bench, but should be kept several yards apart. Nitro powders can readily be exploded without the employment of the caps, but as a matter of fact few explosions of this character occur where the cap is not a factor. It is a subject which should receive careful consideration, as the practice is not uncommon, and accidents are not infrequent from carelessness and violation of common sense rules regarding it.

EACH week notes an advance in the price of copper, and it is now slowly, but surely, nearing 13 cents per pound. That it would quickly go to that figure and beyond, were there not some powerful restraining influence, there is no doubt. The failure of certain large producers to report truthfully, or at all, their production has created a feeling of distrust in the market, and it is generally assumed that the statements of "stock on hand" at the first of the year were very unreliable. The great combination appears to be disintegrating, as one large concern after another withdraws from the pool known as the Copper Producers' Association, apparently owing to lack of good faith. For some time past it has been reported that the large producers were gradually approaching a basis of proportionate production, expecting in this way to control the output and price, in a manner similar to the quicksilver pool, in which the principal producers of that metal in America were concerned some years ago. That a pool of this character would have a great influence on the market there is no doubt, but it has always been difficult for the managers of such pools to hold these combinations with a firm hand, and sooner or later dissatisfaction disrupts the arrangement, which is followed by demoralization of the market.

CONCENTRATES.

HOT-AIR ENGINES can not be operated to advantage with air heated above 350° F.

WHEREVER there exists a difference of temperature motive power can be produced.

AN assay ton is equal to one ounce troy. There are 29,166 assay tons, or troy ounces, in one ton of 2000 pounds avoirdupois.

THE Denver, Colo., average price of silver during 1902 was 52 13 cents per ounce; lead, \$3.50 per 100 pounds; copper, 11.17 cents per pound.

WHEN an acid is added to a cyanide solution containing zinc and also an excess of ferro cyanide of potassium, the zinc is precipitated as ferro cyanide of zinc.

A BODY falling through space, at 1070 feet from the point of starting has acquired a velocity of 254 feet per second, and at 4000 feet is moving 507 feet per second.

IT is a curious fact that rubber belts when run constantly, and not overloaded, will last longer with reasonable care than the same belting rolled up in the storehouse.

FORTY YEARS AGO, this month, in the Florence, Idaho, gold rush, butter brought \$3 per pound, cheese \$1 50, sugar \$1.25, flour \$1, coffee \$2. The gold brought \$12 per ounce.

OSMIUM has the highest melting point of any metal, about 2600° C., and can be used at a higher temperature than carbon in an incandescent lamp, making the efficiency correspondingly higher.

THERE are two chlorides of gold, viz: Au Cl and Au Cl₃. The latter unites with hydrochloric acid and forms the liquid with which photographers are familiar and commonly known as chloride of gold.

RAILROADING is as positive a science as chemistry. The recent recurrence of railroad "accidents" means attempted operation of railway trains in ignorance or defiance of such scientific requirements.

THE function of a steam governor is to act in accord with every variation of the load, and to so limit the quantity of steam to be admitted to the cylinder as to overcome the resistance of the load, thus maintaining a uniform speed of the engine.

MACHINE DRILLS operated under thirty pounds pressure do not do effective work. The drills will last much longer, but the results accomplished by employing a pressure of ninety pounds per square inch will greatly more than offset the cost of wear and tear and of new machines.

THE actual weight of water in a pipe line 12 inches in diameter and 1000 feet long would be 24,486 + tons. The pressure per square inch at the lower end would vary with the difference in height between the upper and lower end, as it is the height of the column of water that determines the pressure.

THE Corliss engine was invented by G. H. Corliss in 1819. Its main feature is the admission of steam to the cylinders by the action of a governor, to determine the point of cut-off at which a liberating valve gear shall act, thus allowing a certain amount of expansion to take place in the cylinder before the end of a stroke is completed.

SHARING DIVIDENDS with the mine employes is not unusual and appears to work satisfactorily. The latest noticed was by Manager Wood of the Ouray Chief, Colorado, mine, who last summer started to allow all the mine employes 10% of all the dividends declared, in addition to their regular wages, the bonus being divided among them pro rata.

GRAPHITES are largely used in pigments and vary in efficiency according to the percentage of pure carbon contained, the form it takes, and the nature of the foreign substances with which the pure carbon is contained. The graphites do not, however, as a rule, adhere well after the first coat, owing to the siliceous nature of the foreign substances so contained.

DOLOMITE is composed of carbonate of calcium and carbonate of magnesium. It forms large rock masses. Much marble is dolomite. Dolerite is a basic igneous rock, composed essentially of lime soda (plagioclase), feldspar, and augite with magnetite and olivine. When olivine is predominant and the feldspar absent the rock is called limburgite, from its occurrence near Limburg, Germany.

IT was stated herein some months ago, but not officially, that the Chilean Government offered a reward of \$20,000 for the introduction into that country of a successful chemical process for the production of copper,

and that the Chilean Government would contribute \$100,000 toward the cost of installation of a suitable plant. The trouble as reported at the time was to the effect that the price of coke, obtained from England, had increased so much as to preclude profit by present processes.

IN rope transmission the sheave should not be less than forty times the diameter of the rope employed, and the groove must be suited to the size of the rope. A sheave turned for Manila rope should have a U-shaped groove. That for wire ropes more nearly approach a V in form. A wire rope should not be run in a groove cut for a fiber rope, or a fiber rope run in a groove cut for a wire rope. In the latter case the fiber rope will cut rapidly and soon break, even if the load resistance be light.

THE treatment of 100,000 tons of uranium residues would probably not result in the production of a kilo of radium. The present market price of radium in this country is \$450 per gram, or, approximately, \$2000 per pound. Radium requires no exposure to light to become incandescent, but will glow for an indefinite time, measured by years, with self-contained luminosity, and has also the property of causing other substances near it to become radio-active, and to retain this activity in some cases for a long period.

AERIAL or wire rope tramways are in successful use in great numbers in Colorado, California, Utah, Wyoming and elsewhere, and are of great commercial advantage. Their first cost and cost of continuous operation can hardly be stated except in the most general way. There are wire rope tramways in Colorado and Utah where the cost of handling ore, including the cost of all repairs, has not averaged more than 4 cents per ton for a year at a time; and there are others where the cost was as high as 25 cents per ton. The difference lies in the original construction and method of maintenance.

WHEN assay samples are pounded in an iron mortar and then ground on an iron "bucking plate," a greater or less quantity of metallic iron is inevitable in the sample, the amount depending upon the hardness of the material—the harder the rock, the greater the quantity of iron. The assayer weighs out his charge with greatest care; and as no account is taken of the metallic iron, the resulting "button" of gold or silver must represent the quantity contained in a lesser quantity of ore than is calculated. This being the case, the amount of gold in a ton of ore is really slightly more than is indicated by assay.

A SMALL quartz mill might be operated by a windmill under favorable conditions—that is, a steady wind of sufficient force to accomplish the desired result. A modern windmill, 20 feet in diameter, will give from 1/2 H. P. to 7 H. P., the velocity of the wind ranging from 8 to 30 miles per hour. A 30-foot mill will give from 2 H. P. to 12 H. P. with the wind varying from 8 to 30 miles per hour. The extreme variability of the wind in most places and the relatively low efficiency of the mills make them generally unsuited for the purpose of operating quartz mills, which require steady power, more particularly where concentrators are in use.

THE difference between rhyolite and felsite is difficult to determine by those unaccustomed to studying rocks scientifically. Rhyolite occurs in sheets and dikes. It has a compact ground mass, in which mica and small feldspars may often be seen. When quartz occurs in visible blebs the rock is called laparite. It is gray, red, brown, violet-brown and other colors. Felsite is light ash gray when fresh and has a close ground mass like rhyolite—sometimes greenish, or bluish, is hard, and contains no visible crystals. When quartz is visible the rocks become quartz porphyry. Both rhyolite and felsite, with their several variations, are associated with important ore deposits.

GYPSUM (calcium sulphate) occurs usually crystalline, sometimes compact (alabaster), or fibrous (satin spar) and crystallized (selenite). These minerals, though frequently mistaken for other substances, are easy of determination. Selenite, occurring in transparent sheets, with perfect cleavage, is often mistaken for mica. It is harder than the latter, and if subjected to a comparatively low heat, as on a stove, quickly turns white. Anhydrite is also calcium sulphate, and occurs with gypsum. It is somewhat harder than gypsum, and usually has a crystalline granular structure. It is distinguished from marble and dolomite by not effervescing with acid and by absence of water.

WHEN one says "nitre," potassium nitrate is understood. It is also known as saltpetre. Artificially it is obtained from the refuse of sinks and stables, in soil mixed with wood ashes to furnish the potassium. The greater portion at present is obtained from the sodium nitrates obtained in Chili, by treating it with potassium chloride. These salts are dissolved in hot water, when they decompose with the formation of sodium chloride (common salt), which separates from the hot solution and is removed, the potassium nitrate crystallizing on the solution becoming cool. Potassium nitrate is a powerful oxidizing agent and is employed in metallurgy. Its use in assaying is commonly known.

FOR heating mills and other buildings about mines where the motive power is steam, there is no economy in

using live steam direct from the boiler as all of its expansive power is lost, the only result being heat, and this can be obtained from the exhaust steam. In employing exhaust steam for heating purposes, provide ample sized pipe lines and the heat can be carried a much greater distance and will give much more effective results. Where desirable or necessary the condensation from the exhaust may be collected in a tank and the water returned to the boiler, but this point of condensation must be far enough removed from the engines and so arranged as to prevent the oil from the lubricators entering the condensed water.

AIR COMPRESSORS can not be satisfactorily utilized to operate power drills, running the air direct from the compressor through the pipe line to the drills. A receiver should always be provided at an intermediate point, and, if the line be long, two receivers are advisable, one near the compressor and one at the nearest point available to the drills. At some mines having auxiliary steam power plants, when the boilers are not in use as steam generators the air lines are connected with the boilers, thus largely increasing the storage capacity and rendering more uniform efficiency. When steam boilers are used in this manner the air may be reheated by keeping a moderate fire underneath the boilers, greatly increasing the expansive force of the air thereby.

"FINE GOLD" is obtained from bullion and alloys by "parting." That is, by dissolving out the base metal with hot nitric or sulphuric acid. For this purpose the metal is usually granulated. Should more than 25% gold be present the refiner adds sufficient silver to reduce the alloy to that value, as, with over 25%, pure gold will not result when treated with acids. Gold may be refined by melting with borax and then passing a stream of chlorine gas through the molten metal. The metals other than gold are converted into chlorides, which can be poured off as soon as the gold has become solid by cooling. As neither of these processes leave absolutely pure gold, when it is desired, the refined gold is dissolved in nitro-hydrochloric acid and precipitated from the solution by oxalic acid or ferrous sulphate.

FOR economical transmission of compressed air the velocity of the air in the main pipe line should not exceed 20 feet per second, and in the small laterals it should be much less than this. Several formulas have been suggested to give a coefficient of friction in pipes, but none of them are satisfactory, as actual practice and experience has demonstrated. The main factors entering into a calculation of the flow of air in pipes are: Unit of time, volume of air, pressure of air, diameter of pipe, length of pipe and difference of pressure at the ends of the pipe, or the head required to maintain the flow, none of which can be given its true value, as each is in a measure dependent on the other factors. Assuming the flow of air to be uniform at the entrance to the pipe, the volume and flow are not uniform after that. The air is constantly losing some of its pressure while the volume is constantly increasing. The velocity of flow is also somewhat increased continually. This also modifies the length of the pipe line as a constant factor.

PHONOLITE is a rock which has attracted much attention in late years owing to its association with important ore deposits in Cripple Creek district, Colo., and in the northern Black hills in South Dakota. It contains as essential constituents an alkali feldspar, elæolite or nepheline, and hornblende. The typical phonolite is described by Zirkel as nepheline-trachyte. It has a compact ground mass, which in its fresh state is dark greenish or yellowish gray. The mass shows a great tendency to fracture in slate-like slabs, and one of these gives out a sharp clear sound when struck, whence the name, but as some other compact rocks can be made to produce similar sounds by striking them this is an unreliable test. The rock is of no particular value or importance in itself, as its occurrence is not always an indication of an ore body in contact with it, or, in fact, anywhere near it. Phonolite exists many miles from any known ore deposits, and other and more familiar rocks are as likely to be found associated with mineral veins.

LIEN LAWS are supposed to protect workmen from loss by failure of their employers to pay them for their time, but the California law, while securing a certain class of workmen at mines (those employed on the surface) does not protect the miner who works underground, the Supreme Court of California having held that that section of the Code of Civil Procedure providing for the giving notice of non-responsibility by the owner of the land or mine, when buildings or improvements are being constructed thereon with his knowledge, does not apply to labor performed underground in the mine. A bill has been introduced in the California State Legislature which is calculated to remedy this defect in the law and afford protection to the miner equally with other workmen, and it will also make any person holding a contract to purchase a mine, and developing or working the same under bond the agent of the owner, thus making the property responsible for the debts of the contractor. Should this bill become a law, there are few property holders who will be willing to turn their property over to promoters or others on a lease and contract to purchase unless such contractor put up bonds to secure the owner against loss by failure to meet the obligations incurred.

Stamp Milling and Amalgamation of Free Gold Ores.

NUMBER IV.

Written for the MINING AND SCIENTIFIC PRESS by DANA HARMON, San Francisco, Cal.

CATCH THE GOLD CLOSE TO THE DIE.—This requires a roomy, rather than a narrow mortar. You can't churn hutter in a teacup, and you must churn if you want to amalgamate. You can't churn with a low, gravel mill style of discharge.

Whenever I neglect my inside catchment the tailings run up. Set the discharge too low and the mortar will throw out on the plates. It is the province of the plates to catch the fine gold, not the coarse. Coarse gold will roll down hill, and the table is a downhill proposition. Coarse gold makes good sized hits of amalgam, and the natural habitat of these is inside the mortar.

On quartz make the discharge $5\frac{1}{2}$ inches at the start, i. e., $5\frac{1}{2}$ inches depth of water measured from the top of the die to the bottom of the screen opening. Starting with this, and with a 6 or 7-inch drop, you will soon have $5\frac{1}{2}$ inches discharge. We will say now that the wear of the die is 2 inches in the month's run. This would mean $7\frac{1}{2}$ inches discharge

build with amalgam, and has also seen it scoured red, in whole or in spots—scoured, we are told, accidentally. Let us dissect this "accident."

Every battery is liable to be filled up with sand. Feeders fail, faucets choke, millmen yawn or are busy elsewhere—no matter the reason, true it certainly is that every battery fills up sometimes. It is

FIGURE 6.

MINING AND SCIENTIFIC PRESS

this fill of sand that scours the chock block. Amalgam once scoured off, is rebellious metal—it is round and hard, it gets out on the plates where it rolls and tumbles, scorning to stick, content only when it

set of the mill's life to make exhaustive tests with screens. The wave motion—i. e., deep discharge with shoe always under water—increases the sliming.

Don't crowd plates with too much pulp.

Don't sluice the pulp over the plates.

Don't be afraid of steep tables.

No distributing boxes.

Don't add water outside the mortar.

These five rules may be treated together.

It is not easy to set down in words just what the conditions of the pulp should be. It is a question to be determined by the eye. Millmen who say they can run their mill by ear should be fired. For these are they who in summer time pick huttercups, or watch the goats gambol on the hillsides outside the mill, and in winter hug the stove in the retort room, poring over some daily or a dime novel. Many a mill owner has suffered because his millman makes of the battery floor a postoffice address. Fortunately for the business, the majority of the millmen are not of that ilk. The point I wish to bring out is that the ear is not a safe guide for the reason that sand does not make noise as it flows over the plate and it is of the utmost importance that the flow be of the right kind.

Plate amalgamation and ground sluicing are two different arts. The first adherence of gold to the plate is quite tenacious if the plate be pasty. Effort must be directed towards forcing the gold to touch the plate. Gravity settles the metal upon the silvered surface. But this is not the only force at

The Mortar Block Tilted and Ready to Place.

The Mortar Block Slipping Down to Its Place.

at close of the run, and would diminish the crushing. To cure this, make one screen frame with 3-inch strip on bottom and 2 inches on top edge; make another screen with 1-inch strip on bottom.

As the run progresses you can change and turn screens so as to preserve a practically uniform discharge.

The drop is regulated by the tappet. Note that the shoe is lifted above the water, the start being made with $5\frac{1}{2}$ discharge and 6 to 7-inch drop.

There is no harm in using a $6\frac{1}{2}$ to $7\frac{1}{2}$ -inch discharge. But there is no gain to amalgamation, and you diminish the crushing capacity of the mill. In other words, work so as to obey the injunction, "Get through all possible consistent with full recovery of the gold."

Some interesting experiments were made at the Utica and Gwin mines on mortar shapes for 900-pound stamps. The hack of the mortar was straightened to 77° . At the discharge line the distance from shoe to back is $2\frac{1}{2}$ inches and to screen $5\frac{1}{2}$ inches. It was found that this mortar would crush five to five and a half tons to the stamp on Utica and Gwin ores, whereas the wide mortar crushed four to four and one-fourth tons—this with No. 2 tin.

I attempted to apply these lines to an 1100-pound mill, but did not increase the crushing, and can only attribute the failure to the fact that the heavier and larger shoe makes a more vicious splash. You can not bring the screen closer than $7\frac{1}{2}$ inches to the shoe. On identical ore the Fig. 1 mortar will out-crush this straight hack Utica mortar, and it is a better amalgamator. Outcrush it because of the greater weight and shoe area.

NO CHOCK BLOCK OR INSIDE COPPERS.—A copper plate in the mortar will attract amalgam. But copper is no greater magnet than is amalgam itself. Start a bed of amalgam in some secure cranny around the dies and you will have as eager an ally. Grooves in the liners are all humbug—they only shorten the life of the liner.

Nobody ever used a chock block hut has seen it

lands in the concentrates or in the canyon. If in the canyon, it is lost for all time. If the buyer of your sulphurets happens to get a hit of it into his sample he rejects the sample as abnormal—these men may be appropriating, they certainly are not huying abnormals. The millman blames the accident he himself has concocted—he has sandbagged himself—for the chock block lies within the zone of scour. Study this diagram, Fig. 6.

Particles of gold and amalgam are flying about within the area a h c d.

These particles can be attracted upward to the chock block or downward below the line 3, 4, as you please. If you use a chock block they will fly to it. If you don't, they will sink around rocks—every particle lodged will attract another; soon it will be a mass. But note the difference; the chock block lying within the zone of scour 1, 2, 3, 4, your caught amalgam is in danger of loss. The zone 3, 4, 5, 6 being below the line of scour, your caught amalgam is safe till cleanup day. Millmen may sleep, faucets clog, feeders huck—your amalgam is safe.

You will find the entire front of the mortar below the line 3, 4 one mass of amalgam—cakes $\frac{1}{2}$ inch to $\frac{1}{4}$ inch thick—this on ore so low as \$5 to \$7 per ton.

Take the year through and you will catch more gold inside without chock blocks than with them.

Another important advantage is that in case of overfeed of quick this excess will be safely absorbed by the mass of amalgam around the dies. Excess of quick on a chock block is fatal—it sloughs off the amalgam.

When one considers the varied duties of the millman and the sudden variations of gold ores there is full warrant for abandoning the chock block.

DON'T SLIME BY TOO FINE CRUSHING.—Especially vicious is this practice on slate ores. The correction can only be located by assaying the tailings through different meshes.

If you slime, you are also wasting power by dead—i. e., useless—stamping. It is a common error, this using too fine a screen. It will pay at the very out-

work. There is another, which, for want of a better single term, may be called propinquity. Don't be in a hurry to sluice off the sand, and don't throw obstacles in the way of these two natural laws. We are now down to the very kernel of amalgamation. We are pursuing the fine gold. A millman who has always worked on \$15 to \$30 ore will be a poor hand on \$3 ore. He has to learn much that has hitherto never entered into his philosophy or dreams.

The pulp must not be too thick on the plates—you don't want a double deck of sand. Furthermore, there should be an even flow of water over the entire plate area. It is for this reason that the center of my plate is $\frac{1}{8}$ inch below the edges—to draw the water away from the edges. Batteries tend to a greater discharge in the corners than in the center. It is a common sight to find a rush of water 4 inches to 6 inches wide along both edges of the table—one-fifth to one-fourth of the plate area is overflowed.

The sand should move over the plates slowly and evenly; the water will go in waves or pulses, while the sand below it will be kicked along by these successive waves, not moving any faster over the last 2 feet than it does over the first 2 feet of the table. Between the waves the sand almost, but not quite, comes to a standstill. Note this point especially: The sand is kicked along; it must never be swept along by a heavy flow of water.

Have a wave and use it. It is these successive kicks that tumble the sand about; before the last plate is reached the gold is kicked into its proper place, viz: to some sticking point. The $\frac{1}{2}$ -inch drop every 2 feet assists the process in two ways: (a) the drop howls the particles over; (b) it prevents acceleration of flow. A drop greater than $\frac{1}{2}$ inch creates too much disturbance and scours the plate.

With this thin, carefully regulated flow and a sticky, pasty plate, good amalgamation will be had. Note the words "sticky and pasty plate." This is in direct contradistinction to the "hard plate", which I do not advocate. The 17-inch lip plate is always hard and is never to be softened with quick

during the run. But from this point down the plates should be kept sticky and pasty—the apron plate will be stiffer than the others, by reason of its making the larger catchment.

Many mills have tables 24 feet long with no break in grade. Drop a cork chip at the head of such table, and at the same instant another chip at the middle. You will find that the second cork will travel its 12 feet in less time than the first one, because the velocity of flow must be accelerated on such a table. If the flow is correct for the first 12 feet, it must be wrong for the second 12 feet.

A suggested cure is to reduce the grade for the last 12 feet. My answer to this is that 24 feet is entirely too long a plate run. The length of the table will depend upon the minuteness of the gold particles in the ore. On some ores 4 feet is ample. On others 6, 8 or 12 feet will be required.

My rule is to preserve the full 5-foot width of plate, maintaining all along the line a sticky, pasty condition until by absorption of the gold it is no longer possible to do so. The point will be reached where free quick, or "glassy" surface, will result. Stop the copper plates at this point. Experimenting on the ore is the only way to determine the length of the table.

This length of table is important, not because of the cost of original installation, but because of the waste of time brushing up an unnecessary length. A 12-foot table is long enough.

Another suggested cure is to give the pulp a run of 4 to 8 feet on a wide plate and to then turn it into a 20-inch plate-lined sluice, set on a grade of $1\frac{1}{4}$ inch per foot.

I thought we had buried this Banquo long ago. But it still crops up and perhaps will be an able-bodied seaman until Gabriel winds his horn. Various reasons are given in support of this theory:

(a) "Tom Jones has been using narrow sluices in his mill for the past forty years. He first used them in 1850 at his placer claim."

(b) "That practically all the gold is extracted after 1 or 2 feet run on the wide plate." If true, then the pulp is ready for the launder. I have never found it possible to catch fine gold on so short a plate run.

(c) "That barren sand or even clear water in quantity coming from a 5-stamp battery will scour and denude a wide plate." This is serious. The waters are deep with no raft in sight. Here are two one-ton lots of sand; one contains \$3 in free gold; the other no gold at all. Both go over the plates—have to, because my poor mine persists in turning out just such alternate mixtures. Will some one tell me which of the two lots is the denuding wretch? Nor can I with safety use even clear water. Let us quit the miserable business and turn scullion so that we can scour without damage.

(d) "That the greater depth of water in the 20-inch sluice gives free play to gravity in settling the metal to the plate." I cannot believe this—sluices don't operate that way. By the time that free gold has passed over 6 to 8 feet of wide plate the gold remaining in the sand is so light that gravity is not the force that compels it to touch the plate. It has to be coaxed there by the slow, gentle flow. It touches the plate because it is quietly forced there by the 4-inch drops and by the wave kicks. It would simply take a jolly good swim in a 20-inch sluice, and would finally elude you. I have spent so much time on my knees with eye as close to the plate as to a hook, trying to read the story told by the tiny waves, that I have become firmly convinced that these minutest particles of gold have little chance to escape from the wide plate with its thin, slow-moving sheet of sand.

With this same pulp on this same plate you can get a wide range of tailing's results by merely changing some of the other factors of amalgamation, viz: screen, amount of water, discharge or drop.

I insist upon holding myself down to the kind of amalgamation that I have been trying to describe. In this there is no place nor compartment for the 20-inch sluice. I am not concerning myself with other kinds of amalgamation, of which we see too much.

(TO BE CONTINUED.)

The State Mineralogist of California, L. E. Aubury, is sending out a circular letter to California owners of mines producing minerals other than gold and silver for the purpose of compiling statistics of production for 1902. The names of neither mines nor owners are to be mentioned in the report, only the aggregate amounts being published under each county head. All mineral States and counties annually publish through some official channel statistics of the mineral production of the State or county, and necessarily the officials in charge of this work must depend upon those owning or operating the mines for accurate information as to output, and as the information thus obtained is treated confidentially, miners would do well to respond promptly to these official requests for data.

An experienced millman says wood ashes can be used to assist in keeping amalgamated plates in good working condition where the mill is not run nights. After shutting off the power at night and brushing up the plates, wood ashes freely sprinkled over them, and wet, can be left till morning.

The Most Effective Nozzle.

TO THE EDITOR:—In current issue of "Concentrates" it is stated that "the greatest efficiency is obtained when the largest possible nozzle is employed which still permits the pressure tank to remain full of water, but without overflowing." This is only partially true, because a point is soon reached when the friction increases at a greater rate than the power generated. For example, a 24 inch pipe, 1000 feet long, with 100 feet head, yields about 90 effective horse power when nozzles discharging 10 cubic feet per second are used. A discharge of 30 cubic feet per second will give 225 H. P. and the maximum effect is reached when 40 feet discharge gives 248 H. P. Sixty feet discharge reduces the effect to 155 H. P., and 70 feet would give only about 15 H. P. (See accompanying diagram.)

Diagram showing efficiency of various nozzles on 24" pipe, 1000 ft. long, 100 ft. head.

Distinguish between "efficiency" and "effect," because the smaller the nozzle the greater is the "efficiency" of the water used. In this example when 10 feet are discharged each foot gives 9 H. P., but when the maximum "effect" is reached each foot of water gives only about 6 H. P.

The practical conclusion is that when water is scarce large pipes and smaller nozzles should be used, but when water is abundant a smaller pipe will suffice, and the maximum effect (not efficiency) will be obtained with nozzles large enough to reduce the static head one-third, as indicated by pressure gauge near the low end of the pipe. In this case the gauge would read about 29 pounds per inch when the maximum effect was being produced, and 43 pounds when the nozzles were closed. R. B. SYMINGTON, M. E. San Francisco, Cal., Feb. 2.

Many queries are received each week from every mining region. To publish these questions would require many pages. Concentrated answers to most of them appear on the third page weekly. The "Concentrate" referred to in the above communication was in answer to a direct question, wherein the inquirer asked whether the employment of a smaller nozzle with a full head of water did not result in greater efficiency than a larger nozzle with the same amount of water, which caused the head of the water column to descend to one-half the height in the pipe line. In reply "Concentrates" said:

"Effective results cannot be obtained with a nozzle of any size when the pipe line is full only half way to the pressure tank, nor is the fullest efficiency obtainable when the pipe at the pressure box is not entirely covered by water, as otherwise air passes down the pipe line with the water, destroying the fullest effect of the stream when delivered at the wheel. The greatest efficiency is obtained when the largest possible nozzle is employed which will permit the pressure tank to remain full of water, but without overflowing. The efficiency is further increased if the water is 2 or 3 feet at least above the top of the intake pipe."

In his communication Mr. Symington overlooks the real purport of the paragraph, which in its entirety is correct, and selects as a text the latter portion of the "Concentrate." Technically he is correct also, as it is well known that the greater the velocity of the column of water in a pipe line the greater will be the loss of power (called head) at the wheel. Hydraulic engineers estimate that when the effective "head" is lessened one-third by reason of friction in the pipe line the highest limit of efficiency has been reached.

Misconceptions in Mining, With an Example.

Written for the MINING AND SCIENTIFIC PRESS by J. H. SHOCKLEY, E. M.

There are, perhaps, more mistakes made in mining, causing lamentable failures and loss of money, than in any other line of business. In nine cases out of ten the reason of this can be assigned to an incomplete knowledge of mines and mining. True, there are instances where the unprincipled mine promoter gulls the public, but in the majority of cases the honest man, with perhaps a few years' experience out West, filled with boundless enthusiasm and an inflated imagination, is the one to whom the loss of fortunes can be directly traced. He is quite often the son of some high official or stockholder in some mining company, born and brought up in the East, with a good education, and his father feels gratified when he sees him start for the West, where after a few months spent in sizing up the situation he is placed in full charge of the work. Very often, however, some friend who is known to be perfectly reliable is selected for manager. He has shown by years spent in association with his friends in the East that he is entirely trustworthy and that they need feel no hesitancy in putting the mine in his hands. This particularly dangerous man appears also many times in the line of promoting. He has probably lived out West—near some mining district—for some time, been fairly successful in his business, and has dabbled in prospects until he thinks he knows something of mining, and finally resolves to try and float some mining scheme. This is comparatively easy for him to do, as his friends in the East endorse him not only with their money, but with endorsement as well to their acquaintances. The above class of men, of course, can have but an inkling of mining. They figure that with a good, reliable foreman in the mine, and a good, reliable millman in the mill, to advise with, they can make no mistakes. But in the simple example given below the conclusion is irresistible that in the majority of cases it pays to have men at the head of mining enterprises who, in addition to being honest, have a broad understanding of mining and a good knowledge of the crust of the earth, and that the mine manager who depends on his foreman and millman is indeed an individual to be feared by the public. No mining man can class himself as proficient who is not well posted in geology.

A few years ago a man who had lived several years in the West thought he had an opportunity in buying a certain mine, and for a considerable cash price, with the aid of his friends in the East, did so. He had no trouble in raising the money, for he was known as a reliable man in business, with experience and some reputation in mining.

When purchased the mine showed some good looking, large sized bodies of both smelting and milling ore, and it was figured that there was smelting ore in sight over the main tunnel more than sufficient to pay for the mine. The former owners were shipping regularly to the smelters and had a stope cut out several hundred feet in length which showed all along continuous ore. The extreme inside workings showed no ore and it was presumed the drift was off the vein in this part of the mine. A winze 50 feet deep or so showed good ore from top to bottom. The formation was granite, which was thought to be good, and the vein was very strongly defined. Operations were begun on a considerable scale—a large mill was put up, with boarding houses and everything for extensive mining. A large working force in the mine turned out heavy shipments of ore and things looked good for the investment. In a short time, however, the ore in the stopes showed unmistakable signs of playing out. Exploration for the vein in the inside workings, where it was presumed the old owners had left it, failed to show ore bodies. The winze on being sunk a little deeper suddenly ran into solid rock and by this time the stopes above the tunnel level were being cut off as abruptly as the vein in the winze. Nearly all the stamps in the mill—now completed, and which had been running full capacity for some time—were hung up for want of ore, and a lower tunnel driven in several hundred feet under the old upper workings had failed to disclose any ore bodies. By this time it was found necessary to shut down the mill entirely and only a few men were on ore in the old stopes, taking out what had been left in the out-of-the-way places. It was decided that the mine was faulted by a series of faults and very extensive search was made to find the vein.

After spending several hundred thousand dollars and two years' time it was decided to hire an expert mining engineer to look into the situation.

He was called to the mine in the middle of winter (several feet of snow was on the ground) and found it situated in the foothills of an extremely high, abrupt range of mountains. Even while going up the trail to the mine, peculiar conditions of the topography caused him to surmise certain things to be afterwards corroborated in the mine workings. Sure enough, the mine was in what is called granite by a good many, but of a hornblende, stratified type, found principally in the upper and outer edge of the

Archæan rocks, and which the mining engineer termed gneissoid schist. Upon entering the mine he found, in the part where the ore had been extracted, evidences of a well-formed fissure, pitching at about 45°, with two walls, and cutting across the formation obliquely, thus forming what is often termed a true fissure vein. It presented evidences of intense movement upon itself, as the ore was much crushed and contained great boulders of rounded ore, imbedded in masses of talc and corroded mineral matter. Not a drop of water was seen in the extensive workings, while the property lay in the foothills of a snowy range. Open cracks were noticeable penetrating the wall rock, evidently of recent date, for they contained no infiltrated matter. Great care had to be taken to secure the hanging wall in the stopes to prevent caving. In the top of the stopes the ore was entirely cut off, as was also the case in the workings below the main tunnel, and extensive work had failed to find any other ore except small hunches close to the main ore body. The ore had been continuous for about 400 feet horizontally and about 350 feet vertically. This block of ore was nearly square and the change from ore to rock was abrupt on all sides. The workings beyond the ore showed what miners aptly term a broken-up condition of the country rock, and, although everything had been followed which looked as if it might lead to more ore, no fissures were found that maintained themselves. Nothing was observed indicating any definite line of faulting.

On going over the surface and from the evidences collected there, such as a characteristically uneven appearance, with hills and hollows and rounded knolls, and abnormal outcrops of the formation, coupled with the evidences presented in the mine, the conclusion was reached that what the mining engineer first surmised on going up the trail was an indisputable fact, namely, the mine was located in a gigantic landslide, miles in area, and all the money had been expended on a segment of a vein at least 3 miles from its original position up the mountain.

A Quadruple Horizontal Pump.

The pumping plant of the Iowa Mining Co., Fresno county, Cal., consists of a setting of four 5-inch Jackson horizontal centrifugal pumps, arranged to work singly or compounded.

This plant, when compounded, delivers 1000 gallons per minute, at an elevation of 50 feet, through 1500 feet of discharge pipe with a pressure at the point of discharge of 115 pounds, and is used for hydraulicking purposes. This machinery is driven by a 62-inch Sampson water wheel. Another plant of this character is that of the Bay Counties Power Co., installed recently near Dobbins, Cal. This plant consists of two special 10-inch horizontal centrifugal pumps, compounded, is belt-driven, and works under a head of 400 feet. The efficiency of this plant is stated to be 74%. During the past six months the Byron Jackson Machine Co. of San Francisco, Cal., has supplied several pumping plants for irrigation and city water works east of the Rocky mountains. The Jordan River pumping plant near Salt Lake City, Utah, consists of four special 40-inch Jackson centrifugal pumps, having a combined capacity of 200,000 gallons per minute, each pump being belt-driven by one 100 H. P. electric motor. The pumping plant for the city of New Albany, Ind., recently supplied, consists of two specially compounded 8-inch centrifugal pumps and works under a head of 300 feet capacity of each 1400 gallons per minute. The plant for the city of Danville, Ill., consists of two special 12-inch horizontal centrifugal pumps with capacity of 5000 gallons per minute at variable heads. There is now in construction in the works of the company special pumps and apparatus for the cities of Fort Worth, Tex., and Elgin, Ill. Among city water works, pumping plants installed in California during the past few months are those of the city of Modesto, consisting of one 85 H. P. automatic steam engine, with special Jackson centrifugal pumps, which furnishes water for both domestic and fire purposes. The pumping plants for the cities of Woodland and Colusa consist of special Jackson high-head pumps driven by direct-connected electric motors.

[The above appeared in the issue of the 31st ult., but owing to a typographical error was misleading in its statement of the efficiency, which is in this issue stated correctly, viz., 74%.]

Henry A. Vezin.

Written for the MINING AND SCIENTIFIC PRESS by
CHARLES H. FITCH.

In reference to the life and character of Henry A. Vezin of Colorado, who lately passed away, I do not speak with any claim of intimacy whatever, scarcely of acquaintance in the ordinary sense; and yet, remote as he was, I feel a certain natural right to speak because he touched me, and I recognized the virtue, the punctilious integrity, of the touch.

I have already read several notices of his life, and have felt how little they said of him, how much they left to be said. The mining engineer, with his large and wealthy schemes, is, in many cases, a man disposed to ornament the truth, to treat his facts luxuriously, extravagantly, even recklessly; his "ore in sight" is an expansive quantity, and when it comes to the grand vista of a prospectus the mining expert has been harshly defined as the superlative of an untruthful man. Mr. Vezin was the antithesis of this. He was keen in his conscience of exact truth. In his insistence upon correctness of statement and detail he might have been thought by looser-jointed minds to be pedantic and fussy. This niceness of integrity went far to define him as a gentleman of the old school.

His feelings were aroused in any discussion involving the truth of principles. He was a hot opponent in advocacy of what he believed to be true. Like Pisanio, in Shakespeare's "Cymbeline," he was a man "not to be shaken" in the faithfulness of his opinions. From what is said by others, I judge his friendship to have been of the same loyal and enduring quality. Whatever other matters in ore reduction may have claimed his attention, I think of him chiefly in connection with the theory of crushing, for until I read his statement of this subject in engineering discussions, I did not realize that crushing had a theory. I can not speak by the hook in citation of his views, but the impression which they made upon me at the time and which appealed to me with the force of value and originality was that all crushing actions and results can be referred conveniently to a cubing fracture.

For example, if we have a cuhe and separate it

three times one face of said cuhes, area of these faces being one-fourth of original face, so that $8 \times 3 \div 4 = 6$ will give the area of cleavage for the second reduction in terms of a face of original cube. The total cleavage area for two reductions will be $6 + 3 = 9$.

If, then, we cube by two cutting into eighths, and again cube by two cutting into sixty-fourths, the power required by the second cubing is to that required by the first as 6 to 3, and the power to effect the finer subdivisions is to the power to effect the coarser subdivision as 9 to 3.

By extending the series we get a theoretical basis of comparison, to which we may refer any work of pulverizing to meshes fine or coarse.

Now, it is obviously true that crushing practically accomplished while an action of shearing or cleavage is not theoretical cubing; but in theoretical cubing we have a working hypothesis and standard of comparison to which all crushing can be referred. When a basis of this kind is established, science is established in the treatment of a subject, for all science is comparative and must be grounded upon standards of comparison.

I do not apologize for explaining this matter in its simplicity, because it is an instance of the comparative method on the lines of which all modern advances have been made—all advances out of the mist of guesswork and superstition into the light of clearly defined truth.

The exposition of this matter, at any rate, established Mr. Vezin in the opinion of the writer as a scientific man, and that, I fear, is more than can be said of some gentlemen on whom colleges have bestowed the degree of Doctor of Philosophy—an American habit neatly hit by Dr. Lorenz of Vienna when he said of his experience in Chicago: "Having some proficiency in surgery, I had to pass examination by the board of health; knowing nothing of law, they made me a Doctor of Laws."

Like most scientific mining men, Mr. Vezin preferred rolls to stamps as a means of crushing ore. The writer represented stamp mill makers, and from some argumentative correspondence he was led to think that Mr. Vezin allowed little field of usefulness for stamps. This correspondence was pursued with much earnestness of conviction until the head of the machinery house suppressed his employe, under the idea that such controversies hurt the business.

I believe that if two men get together in discussion on a scientific basis which admits of no pretense of insincerity, the result is a melting away of all difference of opinion, although one may be benefited by a peep at the common subject from the other's point of view.

There are two significant parallels in politics and in pulverizing. In politics our country in its prosperous years has been committed to a policy of protection, which has been steadily condemned by theoretical economists, such as Prof. Sumner, and, in fact, by all prominent in teaching political economy. In pulverizing, until within a few years, the vast preponderance of practice on gold ores has been committed to stamps, although stamps have been very generally condemned upon theoretical grounds. In these two things teaching has been opposed to practice, and why? This was the question raised by the writer in correspondence with Mr. Vezin several years ago. I had hoped to renew it when relieved of the espionage by which it was then limited, but the pressure of other matters intervened, until now when he has been called away. I believed then, and still believe, that there are two sides to this matter; but the increasing use of rolls in mills has demonstrated more and more largely the opinions in their favor advanced by Mr. Vezin. He wrote warmly, earnestly, like a true scientific man, zealous for the truth, keen to expose fallacies. Like a scientific man, too, he gave me his truth, frankly, freely, without dissimulation, not asking who I was, or whether I had any claim upon him, but as man to man, in his own manliness, in which, with all his sharpness of criticism, there was maintained the courteous hearing of the man who respects himself.

I never heard that Mr. Vezin made any great "stake" in his mining practice. The tributes of respect left at the grave of this veteran were tributes not to the material he had scraped together during his earthly career, but to the richest and most inalienable possession a man can make for himself, the truth and worth of his personal character.

EVERY well organized mine should have a store-room and a storekeeper, whose duty it is to issue the supplies, such as nails, pipe fittings, candles, tools and the great variety of things to which the workmen in some places have free access, "because it saves time" and the expense of the storekeeper, but no record is kept under such conditions and the loss incident to such lax methods amounts to more than would pay for giving this department proper attention. One of the top hands—the carpenter or his assistant, or one of the timber framers—can usually be found who can do his work and also attend the store. At large plants a special man should be employed as storekeeper.

WHEN laying a pipe line for compressed air always provide valves at low places along the line, to afford an outlet to condensation of moisture within the pipe.

Quadruple Horizontal Pump, Iowa Mining Co., Fresno County, Cal.

into four equal smaller cuhes, the area of cleavage will be equal to three times the area of one face of the original cuhe. The power required to effect the separation will be proportional to this area of cleavage. If we now separate the smaller cuhes each into four in the next degree of diminution, the aggregate area of cleavage in this second division will be six times the area of one face of the original cuhe. This

Cube Illustrating Ratio of Crushing Force.

will be clear on inspection of the figure herewith. There will be eight cubes of the first degree of diminution, and the cleavage area in each of them will be

California State Mining Bureau.

Written for the MINING AND SCIENTIFIC PRESS by
W. L. WATTS, E. M.

An inspection of the statutory history of the Mining Bureau shows this department was established in 1880. The first State Mineralogist was H. G. Hanks, who was appointed in 1880.

The Mining Bureau was created in order that a systematic record might be made of the progress of the mining industry in California, and that the mineral lands of the State might be investigated and reported on by competent men, unbiased by local prejudice or personal interest. Also that a public museum might be maintained, wherein samples of minerals and other geological specimens might be displayed; special prominence to be given to specimens representing the mineral wealth of California, together with maps and models pertaining to mining, metallurgy, geology and kindred subjects. Also that a public library should be maintained of books, reprints and drawings, being on the subjects of mineralogy, geology, mining and metallurgical processes.

The executive power for directing the work of the bureau was to be vested in a State Mineralogist, to be appointed by the Governor of the State, the State Mineralogist to confer with the board of trustees in all matters of importance and to render a report to the Governor on the mining industry of the State.

At first the fund created for the support of the Mining Bureau was ridiculously small considering the scope of work which this department had been created to perform. A precarious stipend derived from funds arising from certain taxes on mining corporations and the sale of mining stocks was for a time its only support. To this an appropriation of \$5000 a year was added in 1883. Notwithstanding the meager exchequer of the Mining Bureau during the early years of its existence, much good work was done, and the annual reports issued by the State Mineralogist were valuable additions to the records of the State. Of necessity these reports were limited to a few subjects, and embraced more or less extraneous matter. In 1885 the Legislature appropriated \$20,000 for the support of the Mining Bureau.

In 1886 Mr. Hanks was succeeded by Wm. Ireland, Jr. as State Mineralogist.

In 1887 the seventh annual report of the Mining Bureau was published. This volume treated principally of the fuel of the State, and for the first time petroleum was considered an important factor to the mineral economies of California.

In 1887 the Mining Bureau received an appropriation of \$60,000, at least 50% to be used for geological work in the field. The greater portion of this sum was expended in finding out what minerals of economic value there are in California. This had to be done mainly by personal research; and it was no easy task in a State embracing 157,456 square miles.

The result of work done in 1887 and 1888 was published in the eighth annual report of the State Mineralogist. The value of this report was so apparent that in 1889 the Legislature granted the Mining Bureau an appropriation of \$100,000, 75% to be spent in geological work in the field.

A staff of field assistants was formed and the ninth annual report, consisting principally of special articles, was published.

In 1890 work was vigorously prosecuted. A preliminary mineralogical and geological map of the State of California was drafted. This map was compiled from the most trustworthy data available, supplemented by the investigations of the field assistants of the Mining Bureau. It is not to be supposed that such a map could be absolutely correct. Every one conversant with the subject knows that a mineralogical and geological map of California, correct in all its details, could only be produced by persistent work of a strong corps of field men for many generations. All that was claimed for the map by the Mining Bureau was, that it graphically demonstrated the leading facts pertaining to the mineralogy and geology of California, as far as they were known at the time the map was compiled. There has been a constant demand for this map.

The tenth report contained several valuable special articles and an excellent paper on the geology of the mother lode by H. W. Fairbanks.

In 1891 the Mining Bureau received an appropriation of \$50,000, 60% to be expended for geological field work and scientific research. At that time it was decided that owing to the delay incidental to preparing an annual report, that the report of the State Mineralogist should be biennial.

In 1892 the eleventh report of the State Mineralogist was prepared. This handled the State by counties and contained valuable special articles. This report was shelved at Sacramento until the Legislature met in 1893, when it was published.

In 1893 Mr. Ireland was succeeded by J. J. Crawford as Mineralogist.

In 1893 a new Act was passed by the Legislature for the establishment, maintenance and support of the Mining Bureau.

In 1894 the twelfth report of the State Mineralogist was published.

In 1895 the Mining Bureau received an appropriation of \$50,000, 60% to be expended in geological field work and scientific research.

In 1896 the thirteenth report of the State Mineralogist was published. The twelfth and thirteenth reports are the best issued by the department.

In 1897 the Mining Bureau received an appropriation of \$50,000, at least 60% to be expended for field work and scientific research.

In 1894 Bulletin No. 2, "Methods of Mine Timbering," by W. H. Storms, was published. The first edition of this bulletin becoming exhausted a second was published.

Bulletin No. 3, "Gas and Petroleum Yielding Formations of the Great Central Valley of California," by W. L. Watts. Bulletin No. 4, "Catalogue of California Fossils," by Dr. T. G. Cooper. Bulletin No. 5, "The Cyanide Process," by Dr. A. Scheidel. In 1895, Bulletin No. 6, "California Gold Mill Practices," by E. B. Preston. Bulletin No. 7, "California Mineral Production for 1894," statistics by Chas. G. Yale. In 1896, Bulletin No. 8, "California Mineral Products for 1895," statistics by Chas. G. Yale. Bulletin No. 9, "Mine Drainage, Pumps, Etc.," by H. C. Behr. Bulletin No. 10, "A Biography Relating to the Geology, Paleontology and Mineral Resources of California," by Capt. A. W. Vogdes. Bulletin No. 11, "Oil and Gas Yielding Formations of Southern California, Part I," by W. L. Watts.

In 1897 the Mining Bureau received an appropriation of \$50,000, at least 50% to be expended for field work and scientific research.

In 1897 J. J. Crawford was succeeded by A. S. Cooper as State Mineralogist. In 1897, Bulletin No. 12, "California Mineral Production for 1896," statistics by Chas. G. Yale, was published.

Between March, 1897, and July, 1899, work on the oil yielding formations of southern California and collecting statistics, by W. L. Watts, and on the Randsburg district in Kern county, by J. H. Means, was done.

In 1899 were published Bulletin No. 13, a statistical sheet for 1897, by Chas. G. Yale; also Bulletin No. 15, a contour map of Oil City, Fresno county, by J. H. Means; also Bulletin No. 16, entitled "Genesis of Petroleum in California," by A. S. Cooper.

In 1899 the Mining Bureau received an appropriation of \$50,000, \$20,000 to be expended in making a practical and scientific examination of the mother lode and other mineral districts of California, including the oil districts, and preparing a brief and accurate history of such districts, and the development, product, researches, methods of working, and future possibilities of the mining and oil industries of California, such examinations to be made by competent experts, experienced in California mining, and assistants, all of whom shall be appointed and have their compensation fixed by the Governor in accordance with the tenor of this enactment.

Governor Gage conferred with A. S. Cooper, the State Mineralogist, and the trustees of the Mining Bureau. The State Mineralogist refused to participate in, or to have anything to do with work outlined in the enactment cited, unless he had the appointing of the assistants who were to do the work.

Governor Gage appointed W. L. Watts as State expert in California mining to take charge of the work, and other assistants who were assigned to special details.

During part of 1899 and in 1900 field work was actively prosecuted and the following bulletins issued by the California State Mining Bureau under the direction of Governor Gage: Bulletin No. 18, by W. H. Storms, "The Mother Lode Region of California"; Bulletin No. 19, by W. L. Watts, "The Oil and Gas Yielding Formations of California"; Bulletin No. 20, by W. L. Watts, "Synopsis of General Report of the California State Mining Bureau." The last mentioned bulletin was issued because the general report of the Mining Bureau, which sets forth in detail the condition of the mining and mineral industries in California, could not be printed owing to lack of funds. In 1900 a second edition of Bulletin No. 16 was published; also Bulletin No. 17, statistical sheet of 1899, by Chas. G. Yale; also registers of mines and minerals of Siskiyou, Calaveras and Trinity counties by State Mineralogist A. S. Cooper.

In 1901 Lewis E. Aubury, the present incumbent, was appointed State Mineralogist.

THE MUSEUM.—The Museum is a very important feature of the Mining Bureau. From the establishment of the department the museum was for many years under the charge of H. S. Durden. In this museum are minerals largely from California, but including specimens from all over the world.

Besides the minerals there are models of mines, showing methods of mine timbering and appliances used in mines and in the treatment of ores. There are also views and diagrams of mines, mills, machinery and oil fields, together with maps of mineral bearing regions. The museum of the Mining Bureau is visited by miners, prospectors, students, capitalists and others who are interested in geology and mining.

THE LABORATORY.—In the laboratory of the State Mining Bureau mineral specimens from California are submitted to a qualitative determination free of charge, and to facilitate this work the Wells-Fargo

Co. have authorized their agents to frank all specimens of less than twenty pounds in weight sent to the Mining Bureau from any railroad station in California.

LIBRARY.—The library of the Mining Bureau is open to the public and is furnished with books of reference and reports relating to mining and metallurgy. It also serves as a public office for the State Mineralogist.

The Fluor Spar and Zinc Mines of Kentucky and Illinois.*

Written for the MINING AND SCIENTIFIC PRESS by
F. H. HARWOOD.

Only a few years have passed since the western Kentucky and southern Illinois fluor spar district was first heard of, and only a short time since it has come into prominence as a great producer of fluor spar.

Practically all of the fluor spar mined in the United States in paying quantities comes from Crittenden, Livingston and Caldwell counties, Kentucky, and Hardin and Pope counties, Illinois. [Another important locality producing fluorite is Castle Dome, Yuma county, Arizona, where it is associated with lead ores. It is mined and shipped to California, where it is used in the manufacture of Portland cement.—Ed.]

The western Kentucky district comprises the counties of Crittenden, Livingston and Caldwell, and is reached from the north by the Illinois Central Railroad, and from the south by the way of Princeton, Ky. Entering this district from the south, at Mexico and Crayneville, small stations a few miles south of Marion, are seen great piles of the dazzling white mineral, with a mixture of green, yellow, blue or red, more rarely gray or even black fluor, these different shades of color frequently appearing in the same specimen.

A few miles farther north, at Marion, to the right of the railroad, will be seen the well-equipped concentrating mill of the Kentucky Fluor Spar Co., where the lead and fluor spar are separated. This plant has fifty tons daily capacity. The property of the company includes a grinding plant, where the fluor spar is ground and barreled for the use of glass factories, the production of hydrofluoric acid and the increasing demand of blast furnaces.

To the north of this plant are the works of the Lucile M. Co. Here fluor spar is being mined from a 140-foot shaft. At this depth there is a solid vein of fluor 14 feet wide.

At Marion, Crayneville and Mexico it is common to see dozens of wagons unloading into cars hundreds of tons of fluor spar and carbonate of zinc.

MARION, KENTUCKY.—The city of Marion has a population of 2500 and is a prosperous town, with substantial mercantile houses, large tobacco houses, a flouring mill and fluor spar works.

With the exception of the mine owned by the Lucile M. Co., the fluor spar properties are located south, west and north of Marion, within a few hours' drive.

The Columbia mine is 5 miles west of Marion, about 1 mile from Crittenden Springs. This property was worked for lead twenty-five years ago. At that time the lead was separated from the other minerals by a plant consisting of crusher, rolls and jigs, and for many years it was a large producer of lead ore. The large quantity of fluor spar in the ore was considered worthless and thrown aside. The discovery of lead in Colorado depreciated the value of pig lead to such an extent that the mine was abandoned, and the property has lately passed into the hands of another company. The old shafts are being reopened, new ones sunk and modern mining machinery erected. Within a short time this property will be a producer of both lead and fluor spar.

THE MEMPHIS MINE.—The Memphis mine, owned by the Kentucky Fluor Spar Co., produces thousands of tons of almost pure fluor spar. The mine is 5 miles west of Marion. The spar from this mine passes through the concentrating plant at Marion, where it is ground and shipped to the glass works and to manufacturers of hydrofluoric acid. The engravings on page 81 are views of the mines and works of this district.

The Yandell mine, 3 miles west of Mexico, is one of the largest producers of fluor spar in the western Kentucky district. The entire surface of this property is covered with fluor spar. The workings extend over a length of 1000 feet. Three shafts, each 100 feet deep, have been sunk. The mineral from this mine is hauled to Mexico, the nearest railroad point. The property is owned by the Kentucky Fluor Spar Co.

The Hodge mine, owned by the same company, is a few miles west of Crayneville. A vein of fluor spar 20 feet wide is developed at the 100-foot level. Steam hoists, washers and other necessary machinery are in use at this mine.

The Marble mine is 3 miles east of Crider, Caldwell county, Kentucky. It is owned and operated by the National Lead, Zinc & Fluor Spar Co. of Cleveland, Ohio. They recently completed a concentrating

*See illustrations on front page.

plant that will treat 100 tons of ore daily. Mining is carried on from two shafts, each 100 feet in depth. The ore carries galena, zinc blende and fluor spar.

The Bonanza mine is 1 mile from the town of Lola and 5 miles from Salem. It is one of the best equipped properties in the district. It has electric lights, air drills and all the essentials of a modern mining plant. It is owned and operated by the American Lead, Zinc & Fluor Spar Co. of Cleveland, Ohio. The capacity of this mine is 100 tons of fluor spar per day.

There are numerous other mines in this district in operation, producing large quantities of fluor spar, among them the Tabb, Nancy Hanks, Holly, Larue, Tabor, Asbridge and Evening Star. New properties are being opened over the entire district, and from indications there is a large supply of fluor spar, lead and zinc available.

Salem, Livingston county, Kentucky, in the heart of the western Kentucky fields, 12 miles west of Marion, is a village of several hundred people and is surrounded by fertile farms. The noted mines are the Cullen and Morning Star.

The Cullen mine, near Salem, belongs to the Eagle Fluor Spar Co. of Wheeling, West Virginia. It is the best known property in Livingston county. The vein at the Cullen mine carries three marketable minerals—galena, zinc blende and fluor spar. The zinc ore and fluor spar being of nearly the same specific gravity, the problem of separation has been undertaken by D. Garth Hearne, president of the company, assisted by Thomas H. B. Haase, general manager. The latest improved separating machinery has been placed at the mine and experiments are now being made. If successful, it will result in the western Kentucky field making a large output of zinc blende.

(TO BE CONTINUED.)

Topographic Maps and Geologic Folios of California.

The United States Geological Survey has been engaged since its organization in making a topographic survey and map and in the preparation of a geologic map of the United States. Under the plan adopted, the unit of survey is a quadrangle 15', 30', or 1° in extent each way, covering an area of one-sixteenth, one-fourth, or one "square degree." The unit of publication is an atlas sheet 16½ inches wide by 20 inches high, and each sheet is a topographic map of one of the above areas. As the atlas sheets are uniform in size, the greater the area covered the smaller the scale of the map. The scale of the full degree sheet is 1:250,000, that of the 30' sheet is 1:125,000, and that of the 15' sheet is 1:62,500. The sheet is designated by the name of some well-known place or feature appearing on it, and the names of adjoining published sheets are printed on the margin. The maps are engraved on copper and printed from stone, in three colors. The cultural features, such as roads, railroads, cities, towns, etc., as well as all lettering, are in black; all water features are printed in blue, and the hill features are shown by brown contour lines. The contour interval varies with the scale of the map and the relief of the country. Maps of limited areas economically important are sometimes published which are not in conformity with the general scheme outlined above; these are called special maps.

The progress of this work in California is shown on the index map. Each of the rectangles outlined shows the location and area of a quadrangle of which a topographic survey has been made. The name of the resulting atlas sheet, when published, is also shown, and its scale is indicated by the size of the rectangles; thus it appears that all three scales are used and that the larger rectangles indicate the smaller-scale sheets and the smaller rectangles indicate the larger-scale sheets. Each of the atlas sheets represented by the largest rectangles shows a tract (quadrangle) 1° in extent each way (one "square degree"), or about 3600 square miles, the area varying with the latitude. The scale is 1:250,000, or about 4 miles to 1 inch. The contour interval varies with the relief of the country; on most of these sheets it is 200 feet, on some it is 250 feet and on two 100 feet. Each of the sheets represented by the rectangles intermediate in size shows a quadrangle 30' in extent each way (one-fourth of a "square degree"), or about 920 square miles. The scale is 1:125,000, or about 2 miles to 1 inch, and the contour interval is 100 feet. The smallest rectangles represent atlas sheets each of which shows a quadrangle 15', or about 240 square miles. The scale is 1:62,500, or about 1 mile to 1 inch, and the contour interval is 25 to 50 feet. Smaller rectangles within the larger ones indicate that sheets on both scales have been published for such areas. The whole number of atlas sheets published for California is seventy-five.

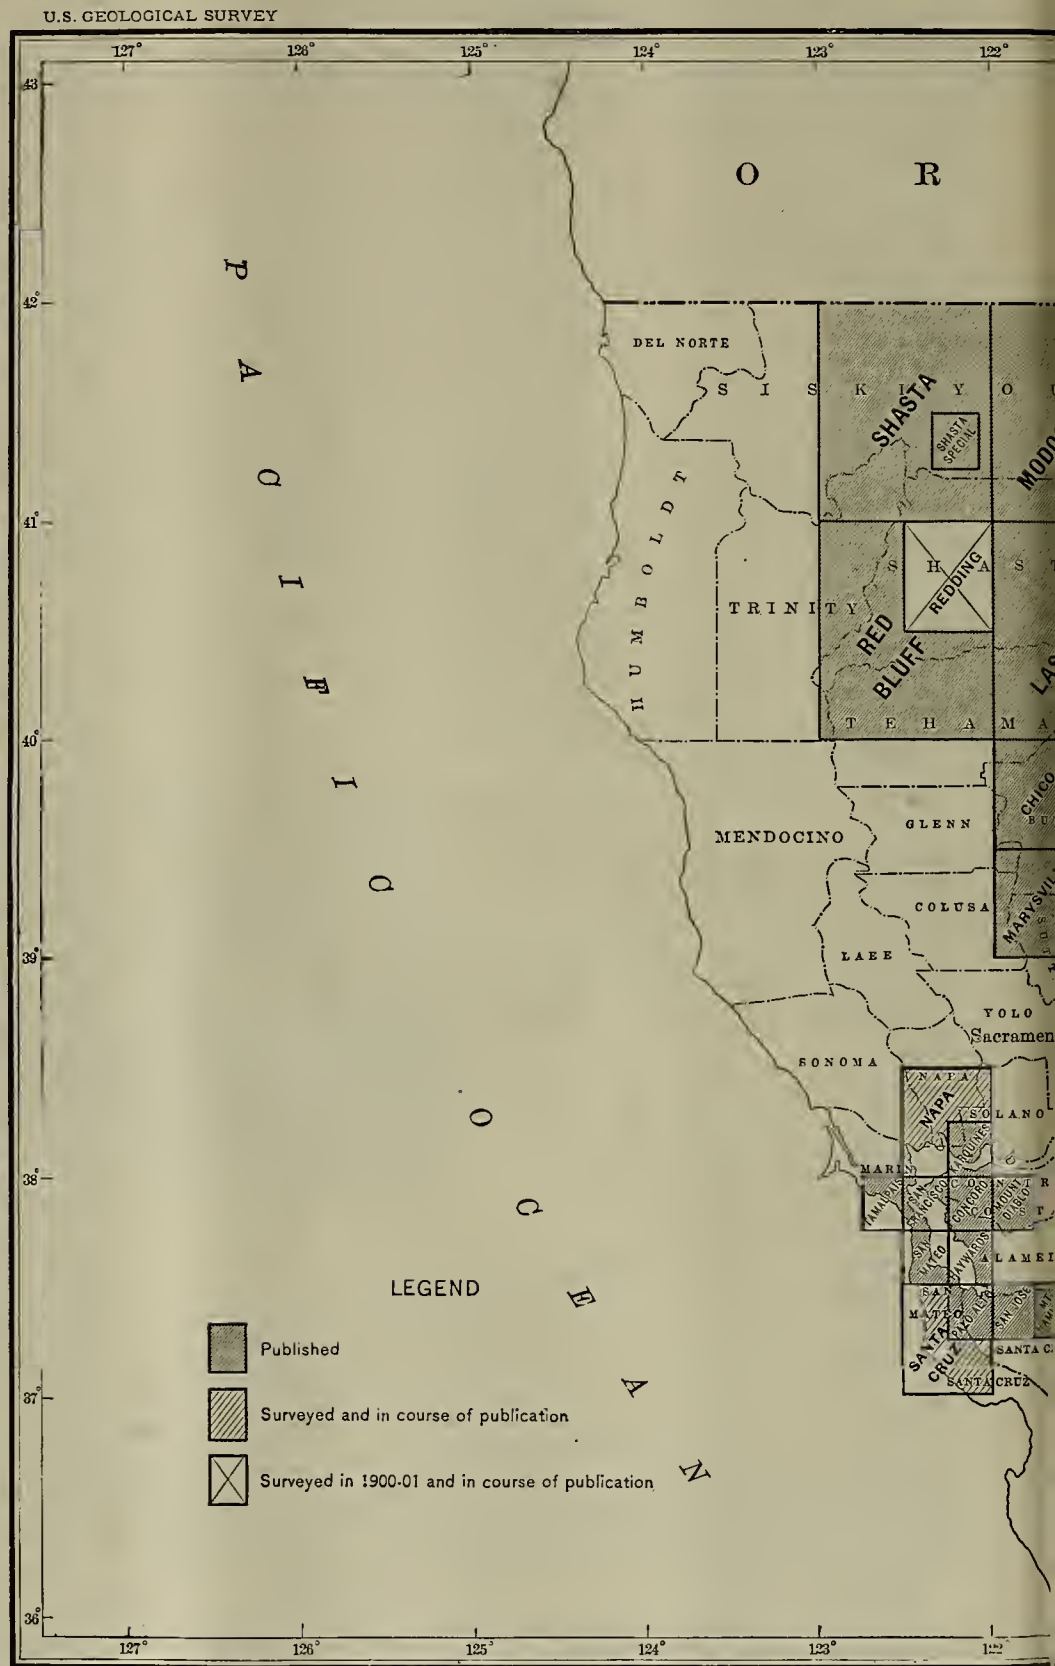

Geologic maps corresponding in position, area and name to the topographic maps are being published in the form of folios. The areal geology, underground structure and mineral deposits are represented by colors and patterns. Each folio contains topographic,

geologic, economic and structural maps of the quadrangle, and occasionally other illustrations, together with a general description. The following folios—to be applied for by name and annexed number—representing quadrangles of this region, have been issued: Placerville, 3; Sacramento, 5; Jackson, 11; Lassen Peak, 15; Marysville, 17; Smartsville, 18; Nevada City Special, 29; Pyramid Peak, 31; Downieville, 37; Truckee, 39; Sonora, 41; Bidwell Bar, 43; Big Trees, 51; Mother Lode District, 63; Colfax, 66.

Under the existing law, the maps and folios are disposed of by sale at practically the cost of paper

rather than return very small amounts of money by mail, unless directions to the contrary are given in the order. The usual price of the geologic folios is 25 cents each. The name of the county should be included in the postoffice address. Prepayment is required, and may be made by money order payable to the order of the Director of the United States Geological Survey, or in cash—the exact amount. Checks and postage stamps can not be accepted.

The readers of this journal do not need any discussion of the value to the civil engineer, the mining engineer, the railroad contractor and the prospector

MAP OF NORTHERN CALIFORNIA, SHOWING

and printing. Index maps of the topographic work in different sections of the country and a general circular upon geologic folios may be had upon application to the Director of the United States Geological Survey, Washington, D. C., who will gladly give further information on the subject.

The topographic maps are sold at the rate of 5 cents a sheet of standard size, or for 100 or more in one order, whether of the same sheet or of different sheets, the price is 2 cents a sheet for the standard size. When maps ordered are not in stock, the right is reserved by the Survey to substitute other sheets,

of these maps and folios. They have already saved to individuals and to corporations thousands of dollars that must otherwise have been expended.

INEXPERIENCED workmen do not usually make good solder. The materials necessary are equal parts of pure block tin and lead, cut into pieces weighing one pound each. Melt, stir and run off into a mould. Solder may be tested by holding a bar near the ear and bending it. If it gives forth a crackling sound (the cry of tin) it is good; if not, reject it, as it has too much lead and too little tin.

American Methods in Manufacturing.

At Claridge's Hotel in London, England, on the night of January 9th, George Westinghouse entertained at dinner a large company of British railway managers, financiers and scientists. Replying to a speech by Lord Kelvin, Mr. Westinghouse said:

"I wish to thank our distinguished scientific friend Lord Kelvin for the complimentary language he has used about me, and I would like to say to all you

resulted from ordinary commercial motives.

"I came here thirty years ago, and for ten years or so I was here about half the time. At that time it was very difficult to get any new thing done in England. I wanted in those early days to try an iron brake shoe, because, on account of rapid wear, we couldn't keep the wooden one adjusted. I had to beg and beg to be permitted to put a set of metal brake shoes on one tender on the Caledonian railway. Finally I succeeded. You all know that nowadays all the railway shoes or blocks are made of cast iron or other metal and are used upon all the wheels of

that among the references cited many are of English origin, some of them containing ideas so complete that the wonder is the inventions disclosed were not established fully and completely in your own land. These records seem to show that Americans and Englishmen have invented the same thing many times.

"In America, however, we have always been short-handed with regard to labor. We have been obliged to find methods whereby one man may accomplish the work of two or three men as compared with your practice here. We have had the best men from Europe—Englishmen, Germans, French, everybody—skilled men, highly trained men, as well as laboring men; we have combined their experience with our own, coupled it with our necessities, and have thus accomplished results unattainable in a country like this where you have more labor than you can well keep employed.

"As an illustration of what has been accomplished by the use of electricity in a great industry, I may cite the Homestead Mills of the Carnegie Company. Mr. Schwab is a genius in his way, particularly in the management of men; he is a master in organizing and directing men. Mr. Carnegie believed in him; and if Mr. Schwab made a suggestion in regard to the use of new appliances, even if it involved the tearing down of an old mill and putting up a new one, the new one was ordered. What Mr. Schwab thought should be done was done. As a result of such progressiveness, we may see the splendid mills at Homestead, where they produce three times as much steel with about 4000 men as the Krupp Works produce with 15,000 men. The results are simply wonderful. You can start there to-day in a building containing steel-melting furnaces, and you will there see three men mounted on a car with the charging apparatus which is moved and operated by electricity. With a few movements of this ingenious contrivance three men charge twenty furnaces, which, prior to the use of electricity, would have required the labor of over 200 men.

"You may go into the yard of the Homestead Mills where they pile the metal in stock. This yard is covered by a system of overhead cranes, and the result is that not only here, but in the mill and in every other place, you may see great weights lifted and many undertakings going on without a single man exerting himself a bit—working not half as hard as I am working now.

"I took some English friends to Homestead. Mr. Schwab, after guiding us through several departments, said: 'I will now show you where we turn out 750 tons of plate girders per day.' The mill was in the shape of an 'L.' We went into the short end of the 'L' where the furnaces were fed by natural gas, of course requiring no stokers. The end at which we entered had a rather low roof, and there was in sight a contrivance like a hattering ram in front of the furnaces. Two workmen were sitting down eating their dinners near by; no one else was present. I thought, 'Mr. Schwab has made a mistake, he has asked us to see a mill that is not in operation.' But we went through the mill, which was about 200 feet long, and suddenly we heard a rattle and then saw a truck approaching loaded with a big ingot. No one touched the truck or the ingot. The load came to a platform, the crane overhead dropped a pair of tongs and quickly put the ingot on the roller table, and, as it moved along to the great rolls, it was automatically kept in place. The adjusting screws of the rolls were turned by little electric motors, and not a man in that house did a bit of work. It was just as easy as what you are doing now—looking on. We went back to the furnaces. There was a fifteen-year-old boy seated in a little place called the 'pulpit.' He was able, merely by the movement of levers, to open at will any of the furnace doors and move the car along. We saw this car come in front of a furnace and the charging machine approach and take out of the open furnace a hot ingot which was dropped on the car and moved off to its work. There was this boy doing absolutely no hard work, and this mill was turning out 750 tons of steel plate each day. My English friends said, 'England has no chance in competition with such methods.'

"Now all this sort of thing came about in America because of our necessities. We had not men enough to do our work. There was a premium in favor of those who could invent machines to work and thus supply the deficiency.

"At the Carnegie Mills we went to see three blast furnaces. They were making 1800 tons of pig iron in twenty-four hours. We saw only two or three men on a truck which was moved automatically. These men were letting the ore run from shoots and mixing it in the required quantity; and when they had filled a truck, it was carried up and its contents dumped into a furnace, whence it returned for another load. They were running the metal into an immense receptacle into which the metal from all three furnaces was mixed. From this place the metal was taken as required, put into a special tank, mounted on a car and taken to Homestead, 2 or 3 miles away, to be poured into the furnace; one heating only was required."

An experimental attempt is being made to convert the tremendous power of moving glaciers in the Swiss Alps to commercial uses.

TWENTY-SECOND ANNUAL REPORT, PART I PL XXII

PROGRESS OF TOPOGRAPHIC SURVEYING.

railway men here present that my life has been very much associated with your calling. I invented the brake, of which Lord Kelvin has spoken, when I was scarcely twenty-one years old, and thus became acquainted with railway men when the railway industry was rather a poor one compared with what it is today. Since then I have closely followed railway operations, becoming acquainted with almost everything that is being done in them, and it is particularly my friendship with railway men which has prompted me to go forward in my work with an interest and keenness that probably would not have

the train. Lord Kelvin has alluded to 'American methods.' May I say that one of your English difficulties is inherent, I think, in an old-world highly developed country. After a man (or a nation) has worked prosperously for a long time, he opposes improvement or suggestion, thinking, 'What I have is good enough; I won't try a new thing.' In America, however, the necessities have produced different results. Lord Kelvin speaks of England having sent many men to America. It has also sent to us many ideas. If you take up the American patent records, and follow the cases in litigation especially, you will find

Mining and Metallurgical Patents.

PATENTS ISSUED JANUARY 27, 1903.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

AIR COMPRESSOR.—No. 719,127; W. M. Myers, St. Joseph, Mo.

In an air compressor, combination with two vertically arranged compression chambers in which liquid is adapted to be reciprocated, horizontal chamber in communication with chambers, horizontal reciprocating piston in chamber, smaller horizontal chamber below chamber and in communication therewith to supply liquid to compression chamber, piston mounted to reciprocate in smaller horizontal chamber to force liquid into pump chamber; an adjustable reciprocating lever connected with last-mentioned piston, rod operated by eccentric adjustably connected with lever to limit throw of piston, motive power for operating lever and horizontal reciprocating piston, of tank to receive compressed air and means to cool liquid before it is supplied to small horizontal chamber.

SELF DUMPING COAL ELEVATOR.—No. 719,009; D. W. Jones, Luhrig, Ohio.

In hoisting apparatus and in combination with suspending frame and tilting platform, vertically disposed catches pivoted to uprights and interlocked at lower ends with platform and uprights to hold platform in horizontal position, and trips extended within path of upper ends of catches to effect disengagement of lower ends from platform.

PROCESS OF TREATING COPPER ORES.—No. 719,132; W. Payne, J. H. Gillies and A. Gondolf, Orange, New South Wales, Australia.

Process of treating copper ores, consisting in first reducing ore to suitable fineness, then roasting it to oxide, saturating with solution of ferrous sulphate or sulphate and chloride, roasting again and adding iron sulphide or sulphur proportionate to cop-

per present, leaching hot ore in water and finally precipitating copper.

ORE CONCENTRATOR.—No. 718,970; F. L. Bartlett, Denver, Colo.

An ore concentrator consisting of laterally inclined shaking table having feed box extending along upper edge and feed water supply pipe extending along upper edge below feed box and having longitudinal riffling which gradually and slowly decrease in height from upper end to lower end of feed box and taper abruptly to lower end of table.

HOISTING APPARATUS.—No. 719,033; A. E. Norris, Cambridge, Mass.

In hoisting apparatus, main shaft, clutch member fixed thereon, friction drum loose thereon and constituting movable clutch member, fixed abutment, thrust collar on shaft between friction drum and abutment, screw in abutment and outside of periphery of shaft, operating lever connected to screw, arc of movement of lever being limited, and means to adjust screw in abutment to compensate for wear, turning of screw operating to give thrust collar requisite longitudinal movement to cause engagement of clutch members.

ORE CONCENTRATOR.—No. 719,181; C. Brown, Bishop, Cal.

In ore concentrator, combination of endwise shaking frame having open center; circular table having central hollow shaft extending through open center of frame; ring having trunnions extending horizontally located at diametrically opposite points and journaled upon frame, ring receiving shaft and providing means for tilting table in plane at right angles to direction of oscillation of frame; arm projecting from ring at right angles to trunnions, and means engaging arm above and below and adjusting position of table; and means for giving table step-by-step rotation.

APPARATUS FOR TREATING ORES.—No. 719,273; Z. B. Stuart, Los Angeles, Cal.

Tank for holding mixture, means to mingle air with mixture in tank and agitate mixture, and adjustable means embracing suction pipe to draw mix-

ture with additional amount of air through circulating and mixing mechanism and further agitate and mix same and return mixture to tank, and means for raising and lowering mouth of suction pipe.

PROCESS FOR TREATING ARGILLACEOUS AND ALKALINE ORES.—No. 719,207; C. H. Gage, Denver, Colo.

The process of reducing argillaceous and alkaline ores which consists in subjecting them to bath of hydrocyanic acid, agitating mixture, adding solution of potassium cyanide, further agitation and filtering mixture, and drawing off solution into bed of charcoal containing solution of iron sulphate, bed being within an electric circuit and subjected to electric current, thereby electrolytically depositing precious metals.

DRY ORE SEPARATOR.—No. 719,397; R. E. Waugh and E. Waugh, Denver, Colo.

In dry ore separator, combination with main frame, of apron frame mounted thereon and provided with air chamber, endless traveling apron mounted on apron frame and provided with electro-magnets located adjacent the inner surface of apron which is arranged to close air chamber, and means for introducing air under pressure to air chamber, apron fabric being such as to allow air from chamber to pass therethrough.

ORE AMALGAMATOR.—No. 719,161; J. E. Sutphen, Albany, N. Y.

In amalgamator, combination of stationary cylinder or shell having paddles arranged to revolve therein adapted to pass through mercury contained in lower part of cylinder or shell and carry it up to various points of discharge through material being treated, with arms swinging loosely from shaft through such cylinder or shell and carrying at upper end of such arms float and at lower end thereof silver plate adapted to prevent violent agitation, jar and concussion of material and mercury and for silver plates to come in contact with mercury.

Mining Summary.

Specially compiled and reported for the
MINING AND SCIENTIFIC PRESS.

ALASKA.

The management of the Alaska Treadwell mine made the following return for December: 240-stamp mill ran 29½ days; the 30-stamp mill ran 5½ days; crushed 43,715 tons ore; estimated realizable value of bullion, \$45,025. Saved 825 tons sulphurets; estimated value, \$10,283. Working expenses for the month, \$64,288.

L. A. Minoque, returning to Dawson from the Chicken creek quartz strike, shows specimens of free milling gold ore, taken from the Matheson lodge on Shadler mountain. He says Tanana and Chicken creek are attracting many miners from Dawson.

J. Leitha, secretary the Holvelta G. M. & M. Co., which bought the Ben Johnson quartz group adjoining the Yellow Jacket on Wndham bay, near Juneau, has begun with twelve men on development. W. A. Heltmann of Seattle is president and general manager.

Letters from Dawson report a strike on the north fork of the Koyukuk river in American territory. Several paying streams have been found in the vicinity, tributary to Seattle river, which flows into the north fork of the Koyukuk. The best pans on the several new creeks average \$38 each. The biggest pay has been found on Masot creek from No. 1 above discovery. Peacher creek, a tributary of Mascot, and Blue Cloud, tributary to Seattle river, below the mouth of Mascot, and Conglomerate show good prospects. On Washington creek was made the first strike in the district—in August—10 cents to 25 cents to the pan being obtained. The strike on Mascot was made Sept. 19.

R. Henderson, one of the discoverers of the Klondike, has reached Dawson from 350 miles up Pelly river. He says winter prospecting shows the existence of gold in paying quantities in many places. Hundreds of streams are tributary to the main river and he predicts another district equal to Forty-mile will be located by spring. One strike has been made on Morgan creek, 10 miles above Hool canyon. Morgan there found gold in paying quantities and had not reached bedrock. He says prospectors along Pelly are scattered all the way from the mouth to 350 miles above—most of them trapping. Winter stampedes are in progress from Dawson to Duncan creek on the Stewart river, where miles of creek bottom are showing pay dirt. Others are hurrying to Tanana, 300 miles distant, from which couriers and letters have arrived describing rich diggings discovered. The stampedes have suffered from cold, with the thermometer at 65° below zero.

ARIZONA.

COCHISE COUNTY.

Manager Briggs, at the Modern mine near Bisbee, is unwatering the shaft, using a bailing skip.

At the Copper Glance M. Co. group near Bisbee, work had to be discontinued in the two-compartment shaft last week on account of water, but the company will install a station pump, a sinking pump, and two 150 H. P. boilers. They will cut a station at the 500 level, and sinking will be resumed to 1000 feet.

At the Silver Throat hoist at Tombstone operations are resumed. It is the intention of the company to sink the shaft to a depth of 1000 feet. Pumps will be put in.

The two-compartment shaft of the Bisbee & Marquette Co., near Bisbee, is down 50 feet, says Superintendent J. Blair.

Superintendent Barker, the Arizona G. M. & D. Co., operating a group of 240 acres, northwest of the Copper Queen mine, near Bisbee, says the tunnel has opened up ore showing values in gold and silver.

Superintendent S. Turner, Calumet & Bisbee Co., near Bisbee, has three shifts at work sinking the two-compartment shaft and expects to cut the main ore body at 1400 feet. This shaft is 300 feet from the South Bisbee No. 3, which is down 1000 feet and in ore.

M. J. Mitchell of Ramsey canyon, operating in the Huachuca mountains, with A. Campbell and W. J. Burner, has a tunnel in 100 feet, which will be driven 3000 feet.

GILA COUNTY.

Reports from the Old Dominion at Globe say freight rates to New York on matte have been reduced to \$11 39 a ton, and they are paying \$11 76 a ton for coke, as against \$19 before the recent shutdown and general readjustment of affairs. The matte and flue dust is being worked up to

provide money for improvements and additions to the plant, including the building of a converter.

At the Untold Globe mines at Globe the Gray shaft has been unwatered and work resumed in the lower levels.

GRAHAM COUNTY.

The Coronado or McLean group of mines at Clifton have been sold for \$100,000 to an Arizona company with W. B. Thompson, manager.

MARICOPA COUNTY.

L. R. Ligler, C. McEwen and C. Lauver have organized the Arizona Granite Co., and will work their quarries 6 miles south of Phoenix, on the north side of the Salt River mountains.

The Oro Grande M. Co., near Wickenburg, will put in a 40 H. P. hoist.—G. Fowler has taken an option on five of the Case-Kent claims, near the Oro Grande.

MOHAVE COUNTY.

It is reported that the C. O. D. Con. Co. at Stockton Bill, 14 miles north of Kingman, will resume. The drift from the 300 level is in 1000 feet. The raise to the surface will be double compartment and used for the main working shaft.

In crosscutting for the ledge at the Lucky Boy mine, at Chloride, on the 500 level, a parallel vein of rich brown iron ore was cut. It is 10 inches thick, found below water level and the gold is free.

The Queen Bee mine at Chloride is putting in a gasoline hoist.

A 50 H. P. dynamo has been installed at the Minnesota-Connor mine at Chloride.

SANTA CRUZ COUNTY.

The Onelda Con. G. & C. Co., operating on the west side of the Patagonia mountains, 12 miles from Nogales, have an inclined shaft on their Arizona claim 80 feet deep, in ore, and a tunnel in 260 feet is expected to cut the ledge 200 feet lower than the bottom of the incline. A 20-ton concentrating mill is contemplated. D. A. Richardson is president.

YAVAPAI COUNTY.

It is reported that W. A. Clark proposes increasing the capacity of the United Verde plant. The six furnaces, with a capacity of 1500 tons of ore daily, will be replaced by five 500-ton furnaces. It is understood that two of the replaced furnaces will be moved 5 miles to the Iron King mine, a copper holding which Clark is developing.

A strike of gold ore is reported in the Catoclin mine, 8½ miles southwest of Prescott. This has always been considered a silver mine. H. Blauvelt is superintendent.

H. Legge, superintendent the White Horse group of mines, 8 miles east of Prescott, reports a strike of oxidized ore at a depth of 65 feet, assaying \$80.

CALIFORNIA.

AMADOR COUNTY.

T. Boyson, owning 600 acres of land in Plymouth district, reports having struck a shoot of gold quartz on his holdings, between Plymouth and the Bay State mine, last week. There are good values in the veins on this property at several points where development has been done.

G. Courtright has three men sinking a shaft on the Spring Hill mine on Jackson creek, near Jackson.

Near Iono, the Tonzi Bros. are putting in an 18 H. P. engine on their mine in Mount Echo district to run the mill.

C. C. Ranlett & Co. are cutting a tunnel into their shaft on the Spring Guich quartz claim, near Electra. Ten tons of the ore recently milled \$7 a ton free gold, says Ranlett.

It is reported that P. Elcheroth of the Sand Pile mine will erect a cyanide plant of 300 tons daily capacity near Forest Home to treat tailings from the Plymouth Con. mines at Plymouth. These have lain there for nearly twenty years.

BUTTE COUNTY.

A club has been organized at Oroville by those interested in dredging. Among charter members are W. P. Hammond, A. F. Jones, C. Hellman, W. Sexton, F. Griffin, O. V. Perry, T. J. Barbour, J. W. Goodwin and H. H. Yard.

CALAVERAS COUNTY.

The Sheep Ranch mine hoist at Sheep Ranch was wrecked last week and work temporarily suspended. A nut from one of the boxes of the shaft fell into the cog gearing. Repairs are being made, but only one reel can be run till new castings are obtained.

The Calaveras Development Co. will begin operations on their hydraulic mines, near Railroad Flat, this month. A. L. Taylor of San Francisco, Cal., is president.

The Nelson mines, at Calaveritas, began hydraulic last week.

Superintendent A. C. Harmon of the Penn M. Co., at Campo Soco, says a hoist

will be put in at the mine capable of working to a depth of 2000 feet.

EL DORADO COUNTY.

At the Capitola mine, 1½ mile north of El Dorado, being operated by G. H. Dithman, G. F. Lewis and W. R. Tong, they have a party shaft down 35 feet, where the quartz assays \$8.

KERN COUNTY.

(Special Correspondence).—The Standard D. M. & M. Co. of Los Angeles has completed the assessment work on their property near Randsburg. Five claims are included in the group. Randsburg, Feb. 1.

The Potomac Oil Co. has contracted its oil to the Southwestern Refining Co., which is building a plant near the Standard Oil Co.'s tanks in Kern River field, near Bakersfield. The Potomac is preparing to drill two more wells, as is also the Columbian and the Continental.

The Four Oil Co., near Bakersfield, has begun drilling, and the Black Jack on the same section and the Alma and Alma, Jr., will begin next week.

The San Diego and Rustler claims, near Randsburg, are reported sold to A. C. Burcham of Los Angeles for \$60,000. These claims adjoin the Yellow Aster mines on the west.

The Keno and Faro mines, near Randsburg, have been sold to A. L. Morris of Los Angeles for \$60,000. There is a shaft on one of them 120 feet deep.

LOS ANGELES COUNTY.

(Special Correspondence).—San Gabriel canyon mines are being operated by a number of companies. One of the latest to secure holdings in that vicinity is the Standard D. M. & M. Co. of Los Angeles. Work has been done in developing the property. Azusa, Feb. 1.

NEVADA COUNTY.

The Peabody mine at Gold Hill, near Grass Valley, has been sold to a company of Puget Sound men for \$125,000. Work will begin this month.

Grading has begun at the North Star mine's power house for a 300 H. P. air compressor. This will be utilized in conjunction with the plant now in operation, says Superintendent A. D. Foote.

PLACER COUNTY.

The offices of the Hidden Treasure M. Co., near Michigan Bluff, have been removed from Sunny South to Centerville, at the mouth of the main tunnel, which is in 5 miles under Forest Hill divide.

The Hings Hill mine at Iowa Hill resumed last week.

At the Bonnie Boe mine at Dutch Flat the 5-stamp mill is in operation.

SACRAMENTO COUNTY.

It is estimated that there are 300 men engaged in placer mining in the district around Folsom. The Gray Wing has 81 men at work, the Red Canyon 40, in its shafts and tunnels, and the El Dorado Con. 75. J. H. Roberts of Sacramento has 20 men developing ground near the Gray Wing and has put in hoisting works. On the Fassler ranch J. Woods has men at work prospecting with a drilling machine. The Blue Ravine Co. is operating on the Murray ranch. The Sutter M. Co. of Sacramento has a Keystone driller exploring their ground.

SAN BENITO COUNTY.

H. H. Bradford, one of the owners of the Cerro Bonito quicksilver mine, near Hollister, says they have men at work building ore furnaces, and will begin reorting by March 1.

SAN BERNARDINO COUNTY.

(Special Correspondence).—The Providence Mountain M. Co. of Los Angeles, owning property in the Providence mountains, report the Iron mine turning out well, the shaft being down 112 feet. The ore body, which was 8 feet wide on top, has swelled and the shaft at the bottom is all in ore of a better grade, being hematite, containing 60% iron, little sulphur and only a trace of phosphorus. No titanic acid has been found. There are twelve claims in the group. The company owns other groups in this vicinity, among them the Fair and Square gold and silver mines, which are being developed. The shaft is down 75 feet in 6 feet of ore which assays from \$9 to \$168 gold and silver. The country rock is porphyry and decomposed granite.

At the Golden Zone group the main ledge is 16 feet wide, giving returns of \$6 40 to \$11 per ton. Two hundred and seventy feet of work has been done on two of the claims.

The Wolframite group of three claims is also being worked. Wolframite was discovered at the surface, while at 50 feet in depth a 5-foot ledge of gold, silver and copper ore is found, the wolframite gradually going out of the vein.

The Desert country generally is looking

well and many large low-grade properties are being developed. The Ludlow mines, owned by Eastern people, known as the Bagdad M. Co., are being developed. These mines are 8 miles south of Ludlow, a station on the Santa Fe Railroad, and a branch line is being built to the property which is nearly completed. E. H. Stagg is manager and L. E. Porter superintendent. The 50-stamp mill erected for custom ores at Barstow is owned by this company and is run twelve hours per day on the best ores from these and other mines owned by the company. The J. R. Gentry group, near Ludlow, has been bought by the same syndicate and are giving employment to a number of men. This company, while being the same people, is called the Benj. E. Chase G. M. Co. They have a large body of low-grade ore and have eight claims in the group.

G. B. Mier and associates, who own the Lava Bed group of mines south of Lave, in the Lava Beds district, are putting up a mill. Over 1200 feet of development has been done on a ledge 20 to 30 feet in width carrying some lead, and will concentrate. A small vein of ore has been located that assays from \$25 to \$35 gold per ton.

J. B. Osborne is working seven men on the Osborne group, in Ord district, 14 miles south of Daggett. There are twenty-three claims, eight of them patented.

The Malachite C.-G. Co. of Los Angeles is developing property adjoining the Brilliant mine of the Osborne group, in Ord district. Men are developing the property.

A 10-foot lodge was recently struck by W. Bailey, 4 miles west of Ord mountain, showing free gold.

C. A. Burcham of Los Angeles is developing a large low-grade prospect adjoining the Waterloo mines in west Calico. Over 600 feet of tunneling has been done and streaks of high-grade ore found, the mineralized formation being 400 feet wide.

The St. Elmo mine, near Johannesburg, has been bonded by S. W. Dorsey of Los Angeles and Eastern associates. Work of clearing out the mine and opening up new ore bodies has commenced.

Gold Mountain mines, owned by J. R. DeLamar, have shut down for the winter. Forty men were employed under the management of Superintendent Doble.

The Black Hawk mines, 50 miles east of Victor, in the Black Hawk mining district, are reported sold and work about to commence.

Barstow, Feb. 2.

L. M. Gregory of Los Angeles, president of the Giant Ledge G. & C. Co., owning a group of nineteen claims on New York mountain, near Manvel, says they have a ledge 50 feet wide, carrying values in gold and copper. The ore is a concentrating and smelting proposition, and a plant will be installed to handle it.

J. Johnson is developing a gold and copper mine at Dale and reports four companies operating in the camp, 50 miles northeast of Walters station.

In the Gypsy mine of the Gordon group, near Death valley, last week G. Harvey, H. Phillips and G. Thomas, while re timbering the shaft, were buried by a cave-in and killed. The shaft timbers had been weakened by an explosion and were unable to withstand the strain when the wall began to sink.

SAN DIEGO COUNTY.

Superintendent Wauchope of the Noble mines, near Pine Valley, says he has twenty-five men at work, but will increase the number. These mines are southeast from Stonewall.

SANTA CLARA COUNTY.

(Special Correspondence).—The copper mine in the Hacienda canyon has been opened by Mr. Kitchen, a Swedish mechanical engineer of San Jose. There are some carbonates, but mostly native copper and red oxide, partly in serpentine, but mostly in altered greenstone. New Almaden, Jan. 29.

SEASTA COUNTY.

Thirty-five feet of the 112-foot tunnel in the Hawaii mine on Clear creek, near Redding, caved in during the storm last week. The Hawaii is one of the group being developed by the Connors G. M. Co. and the ore body shows gold and copper values.

Four hundred men are now enrolled by the Mountain Copper Co. at Keswick. Tuesday 100 new men applied for work. They comprised strikers, old employees and new men. The first furnace is now in operation. General Manager Wright states that in settlement of the strike the company made no concessions, and there will be no change in the policy of the company toward its employees, employing whom it likes and discharging whom it will. It admits of no dictation in the conducting of its business, and would, on the recurrence of the recent trouble, shut down its plant for an indefinite period.

A strike has been called at the Bully Choo quartz mine, 50 miles west of Red-

ding. Thirty-five men employed in the mine and mill quit on the 4th inst. because their demand for an eight-hour instead of a ten-hour day was not granted.

SIERRA COUNTY.

A Los Angeles company is reported to have bought Vineyard & Freeman's Cash in the Dump group of mines at Meadow Lake, near Sierra City. A 20-stamp mill will be erected in the spring.

SISKIYOU COUNTY.

It is reported that the Black Bear group of gold mines, near Black Bear, has been sold to the Illinois M. & R. Co., J. A. Shetty general manager, New York City, who will begin operations this month, and electric machinery will be installed.

SONOMA COUNTY.

The Banner gold mine, 4 miles south of Cloverdale, partially on the Italian-Swiss colony ground, will be operated. Coe, Hyatt, Whipple and the colony people are the owners.

TRINITY COUNTY.

Superintendent G. Lowden of the Three Peaks mine on Coffee creek, near Carrville, says a 4-foot ledge has been struck in one of the drifts and the 10-stamp mill will be in operation next week. It is the intention of the company to put in an additional ten stamps next summer.

A portion of the flume of the La Grange Hydraulic M. Co., near Weaverville, where it crosses Garden gulch, was torn out by a landslide last week. Foreman J. E. Shand has begun repairs.

The Harmon mine, on West Weaver creek, near Weaverville, owned by Meckel Bros., is working a 10-foot bank of gravel.

In the lower tunnel on the Bull of the Woods mine, near Weaverville, a 2-foot ledge of gold ore has been opened. The owners, Montgomery & Byers, have a 2-stamp mill on the property which they propose to enlarge.

The Three Sisters mine, near French Gulch, has been bonded to H. Franck and J. Blagrove.

C. W., J. P. and J. T. Booth are working their hydraulic claim on Oregon mountain, near the Sweepstake, near Weaverville. They have an 8-foot bank of gravel and are running four hours a day.

The Bob's Farm M. Co. has been incorporated at Sacramento and will operate the Bob's Farm group of mines in Rattlesnake district.

TUOLUMNE COUNTY.

At the Cosmopolite mine, near Groveland, under bond to J. M. Merrill, the vein has been struck in the crosscut at 240 feet from the shaft and 500 feet below the surface. Superintendent H. Argall says the ore shows sulphurets and free gold, and a stamp mill is proposed.

J. J. Scofield, W. T. Lewis and D. Newman have bonded the Mastodon mine on the mother lode, near Groveland, for two and a half years, for \$15,000.

The mill on the Spring Gulch mine, near Carters, resumed last week to make a test run on 100 tons of ore. The mine is under bond to a Denver company, with K. C. Parrish as superintendent. The shaft is down 500 feet and a drift is being run to tap the ore shoots opened in the upper levels. The same company has a bond on the New Era (the Hunter mine), also near Buchanan.

The Kodak mine, on the North Fork, near the Providence, near Carters, has been bonded to W. E. Perry of Boston, Mass.

H. J. Dykes is opening up the Punter mine, southwest of Sonora. The shaft is being unwatered and retimbered.

At the Mountain Belle mine, near Soulsbyville, under bond to W. Sharwood, they are crosscutting on the 100-foot level, with six men at work. A hoist is already on the Mountain Belle and a compressor will be added.

The storm of last week flooded the Two Brothers mine, near Groveland, and all work was stopped. Unwatering is under way, says Foreman Reid.

The Pine Nut mine on Turnback creek, near Carters, has been bonded to C. L. Lang of Sonora.

Superintendent F. Chappellett of the Mohican mine, near Groveland, says they are working on a 15-foot body of ore and intend to put in a hoist underground 500 feet from the mouth of No. 1 tunnel, through which ore will be sent to the mill.

An Idaho company has a bond on the Vivian and Kanig mines, near Parrott's Ferry, on the Stanislaus river, near Columbia, and are opening it by a tunnel.

At the Draper, near Soulsbyville, the shaft is down 600 feet and crosscutting for the pay shoot begun. Ore is being stopped from the upper levels.

The foundation for the 10-stamp mill at the Altadena, near Columbia, is in place, says Superintendent C. A. Holland. The

shaft is being unwatered and sinking will be resumed.

W. T. Carter of Carters has bought a one-third interest in the Old Croesus mine, near Carters.

J. M. Merrill of Alameda has bonded the Cosmopolite quartz mine near Groveland for \$10,000.

COLORADO.

BOULDER COUNTY.

The Great Western M., M. & S. Co. has been incorporated at Boulder to operate several properties at Magnolia, Crisman, Sugar Loaf and Springdale and to conduct a sampling and refining business. The company is operating in the Anna Clark lode at Magnolia and the Decatur tunnel at Crisman. R. E. Dunsmore, C. N. Page, W. Koehler, Jr., C. L. Lewis, A. M. Hunter and A. T. Geiger are the officers, with W. A. Brockway manager.

A. Matt made a 20-ton shipment to the sampling works last week from his lease on the Little Joe, near Wall Street.

The Nancy Co. has started a stope on the Gillard vein, 300 feet from the crosscut.

Four tons of smelting ore were shipped from the Last Chance Jan. 30.

The Wano mine, at Jamestown, under Superintendent A. H. Brown, is showing a 25-foot body of ore that runs \$25 per ton.

W. Brown of Boulder is unwatering the Invincible mine preparatory to development. Superintendent G. Brinker of the Wandering Jew is driving a raise from the tunnel through to the surface, when he will put on a gasoline hoist.

CLEAR CREEK COUNTY.

G. Woodring, manager of the Mary Ann mine, near Georgetown, says a contract has been let to drive 100 feet on the vein where 3 feet of quartz is showing. A water right has been bought to develop power for drills, and a mill later on.

O. Shepherd reports carbonate of copper in the Buckeye, near Georgetown, with 12 inches of lead ore on the wall. An 8-inch streak of gray copper has been found in the Comet averaging \$68 per ton, says Superintendent F. A. Maxwell.

Aldridge & Co. have opened a 6-inch streak of gray copper in their lease on the Kirtley, near Georgetown.

Schauers & Noone have a bond and lease on the Magnet-Sequel group and have men at work on the first and fourth levels.

Haggart & Riley, working on the Edgar lode, on Democrat mountain, near the Rogers and Providence mines, have struck 10 inches of sulphurets ore.

The Vidler tunnel at Argentine is in 300 feet and is 8x8 feet in the clear. It is to be 7000 feet long. Work continues by hand until the machinery is installed. R. C. Vidler is manager.

A. E. Reynolds, owning the mines on the west part of Red Elephant mountain, near Lawson, is installing machinery for development work.

R. Willis, of Colorado Springs, says he will install a mill on his East Red Elephant millsite, near Lawson.

CUSTER COUNTY.

The P. & O. mine at Querida is showing up tellurides in the ore shoot.

EL PASO COUNTY.

The Colorado-Philadelphia mill of the United States R. & R. Co., at Colorado City, is reported closed down indefinitely.

FREMONT COUNTY.

The shaft house on the Lone Tree mine, near Florence, is finished and sinking in the main shaft resumed. The El Motor and American Flag have resumed. The shaft of the El Motor is 150 feet deep. At the Hector, owned by Jennings Bros. of Cripple Creek, the machinery is in position, pumping has begun and the shaft is being timbered.

The Florence Portland Cement Co. has incorporated to work 440 acres 6 miles east of Florence and near their mill; J. Q. McDonald, J. W. Cline, E. H. Carpenter, J. E. Broadhead, W. C. Parker, J. D. Blunt, W. Kelso; 300 acres of the company's ground contain deposits of shale, limestone and clay. Two millsites have been surveyed. It is intended to install a plant of 1000 barrels daily capacity.

GILPIN COUNTY.

Manager O. B. Thompson, of the Boston & Denver Con. M. & M. Co., says the properties of the company near Blackhawk are to be reopened, and operations begun on a larger scale than before.

The Four Mile Gulch T. M. Co. is working both the Wheeler and Klondike tunnels, near Black Hawk, the former being run in from Silver gulch and the Klondike from Dory gulch, the object being to drive the tunnels till they meet, says Superintendent Brohl. Their ore carries silver, lead and gold values.

D. H. Allen has taken a lease from the

city of Black Hawk on the slag deposit on the site of the old smelter of the Boston & Colorado, and has men at work to take out the slag. It is estimated there are 3000 tons in the bed of North Clear creek, carrying values of \$5 per ton, wanted by the Denver smelters for fluxing.

A strike in the Old Town mine, in Russell gulch, has been made, says Manager Kimball, showing a body of copper ore in sinking the shaft at 850 feet. At 890 feet it shows 2 feet wide, running three ounces gold, sixteen ounces silver and 4% copper. It is the intention to sink the shaft to 1000 feet.

The Monarch tunnel, near Idaho Springs, has resumed crosscutting with machine drills. The company owns the Freeland group of mines and is driving the bore to reach that property a distance of 1 mile. The Topic Co. has completed sinking a winze from the tunnel level and has opened up a body of milling ore to a depth of 800 feet. Drifting has begun.

Sinking of the shaft of the Arizona mine, near Idaho Springs, is under way, says Manager Morgan, and opening up a body of sulphide ore, which will be followed for another 200 feet and drifts run on both sides to the east, connecting with Morning Star, recently bought by this company.

The Freedom mine on Winnebago hill, near Central City will be operated by the Colorado & Tellurium M. Co., under a three years' lease and option, with W. W. Emmett as superintendent. The main shaft is down 850 feet and machinery will be ordered.

The Kemp-Calhoun mine at the head of Leavenworth gulch, near Central City, Manhire Bros., lessees, have the shaft down 275 feet and drifts started from that point.

Wright, Lilly & Co., of Colorado Springs, have taken a lease and bond on the Golden Dollar mine, northwest of the Prompt Pay mine in Russell district. They have miners at work in the 125 east level, from which they are taking out smelting ores, showing copper, lead and gold values; also hoisting milling ores and have made a three-cord shipment. E. Williams is superintendent.

GUNNISON COUNTY.

Manager A. Lejune has men at work driving the Blistered Horn tunnel, near Tin Cup.

In the Goodhope mine at Vulcan is reported a 3-foot vein of ore associated with tellurides, on the 500-foot level.

HINSDALE COUNTY.

The Dwyre M. Co. has taken a bond and lease on the Inez and Hollister claims, which adjoin the Isold mine, near Lake City, for \$80,000.

The concentrating mill of the Red Rover M. Co., treating low-grade ores from the Lellie mine, near Lake City, is turning out five carloads of concentrates per week, says Manager Farrell.

LAKE COUNTY.

In the main west drift toward the Resurrection from the Diamond shaft in Big Evans gulch, near Leadville, at a depth of 1000 feet a body of lead carbonate has been found, says Superintendent Brooks.

J. McGoff & Co., at the Little Troy near Leadville, are working a body of low-grade gold, silver and lead ore. The Hudson and Belmont, adjoining claims, report the same kind of ore. H. Dyat has struck a body of lead ore in the Peerless Maud showing lead sulphate.

Manager J. Shinn, of the Stormy Petrel M. Co., has men doing development work on the Lizzie Lou mine, on Horseshoe mountain, near Leadville. The Gold Basin has decided to prospect in the lower quartzite and is drifting to locate the vein previously exposed.

Work has begun on the Black Prince mine, near Leadville, under lease to the La Belle M. Co., with T. Owens as manager.

It is reported work had to be abandoned on the O'Neil shaft, started on North Fryer hill, Leadville, to tap the Progressive ore chute, on account of the flow of surface water. It is proposed to start a new shaft higher up the hill.

Manager J. W. Deane, of the Valley M. & L. Co., has arranged with the railroad company to place a switch to the Valley mine and to the shaft on Little Ellen hill, near Leadville. The Valley shaft is being deepened.

M. P. Murray, manager of the Ball Mountain M. Co., has started a shaft on the north side of South Evans gulch, near Leadville, and is down 60 feet.

The A. Y. & Minnie mill at Leadville is treating 100 tons of zinc-lead ore per day.

LA PLATA COUNTY.

The Aurora G. M. M. & T. Co. has been incorporated under the laws of Wyoming, to operate in the Oro Fino district, 1 mile

north of the Durango Girl, near Durango. J. T. O'Hara, of Durango, is manager. The ore is said to carry telluride.

LARIMER COUNTY.

Putnam & Barnard, contractors on the Greyton mine, near Pearl, are sinking the shaft an additional 50 feet. The Greyton is in State Line camp, 4 miles north of Pearl, and adjoins the Bonbright property.

MINERAL COUNTY.

An air plant will be put in at the Monte Carlo Co.'s mine near Creede, consisting of a gasoline engine, fan and pipe, says Superintendent Z. Wilson, after which he will resume driving the tunnel.

OURAY COUNTY.

The Tempest and Micky Breen groups near Ouray are sold to Denver and Chicago men, who incorporated as the Tempest Apex M. Co., with F. McLaughlin of Denver, president, and F. M. Jackson, vice-president and manager. The Tempest is near the head of Poughkeepsie gulch. The Breen mill will be overhauled and additional machinery put in.

SAN MIGUEL COUNTY.

The Boston-Telluride M. Co. will build a concentrating plant on its millsite at Pandora, 2 miles above Telluride, and also a tramway from the mill to the Japan group of mines in Savage basin, a distance of 2 miles. The tunnel on the Japan is in 2100 feet, and is expected to strike the vein at 2700 feet, a depth of 850 feet from the surface, and 640 feet below the upper workings.

A strike of sulphide ore is reported made in the Silver Tip mine, owned by D. Martin of Ophir, and shipments of \$20 gold ore are being made. The mine is 1½ miles east of Ophir and the ore is from a depth of 150 feet in a 400 foot tunnel, with the pay streak 15 inches in width.

The 80-stamp mill of the Smuggler-Union M. Co., at Telluride, is crushing 300 tons of ore daily. The concentrate shipments from the mill and tailings plant amount to eighty carloads per month.

SUMMIT COUNTY.

The Colorado & Wyoming Co. operating the Wellington-X-10 U-8 group of lodes, on Mineral hill near Breckenridge, report in the main crosscut tunnel, at 580 feet, a vein of iron, lead, silver and zinc ore and at the 615-foot point an 18 inch streak of galena. The vein, for 33 feet in width, is a milling proposition and a concentrator will be built, say R. W. Foote, G. H. Evans and O. K. Gaymon, the owners.

Superintendent J. Hickey is driving the main tunnel of the Dreadnaught mine near Breckenridge.

The owners of the Bird's Nest group at Kokomo propose driving a crosscut for drainage. The tunnel will cut five veins before reaching the Bird's Nest at 250 feet in. Owing to a flow of water it was found impracticable to sink on the Bird's Nest.

B. S. Revett has organized the Oro Dredging Co. to operate in French gulch, at Breckenridge, and will operate two dredgers to cost \$75,000 each.

H. D. Crawford, J. B. Allind and S. M. Stuart, of Denver, have bonded for \$25,000 a group of claims northwest of Frisco. They will build a mill on the Victoria claim and work the Victoria vein, a free-milling ore.

The Wellington mine, near Breckenridge, is being opened up by lessees R. W. Foote et al. Machinery is being put in and the lower tunnel is near the vein.

TELLER COUNTY.

Last week the night shift resumed work in the Arequa mill at Cripple Creek, under lease by A. H. Heller, who has been operating but one shift. He has bought the dump of the Wild Horse mine, of the United Gold mines. Work has been resumed on the Little Ella, on Raven hill, Cripple Creek.

Shipments were resumed last week from the Mollie Kathleen, on Womack hill, Cripple Creek. H. D. Gortner, owner, says the ore is coming from the 700-foot level.

It is reported two cyanide mills will be built near Gillett, one of which will work the tailings dump of the Gillett mill, with a capacity of fifty tons a day. The other will be erected by S. M. Dilts, who owns thirty acres on Carbonate hill, near the Michigan pipe line, which will furnish water for mill purposes.

Shaft No. 3 on the Portland, at Cripple Creek, is down 1250 feet and cutting a station begun. The first level run out will be to the Burns shaft, which will be cut at 1000 feet.

That portion of the Jeremy Sample mine, Cripple Creek district, under lease to Bahbitt Bros., is producing twenty-five tons per week from the levels at 200 and 400 feet, the rock averaging \$40 per ton.

The Par Value G. M. Co., D. Heaton manager, operating four properties on

Battle mountain, near Victor—the Dillon, the north end of the Monument, the Mary Cashen and the north half of the Coriolanus. From these, except the Monument, they are shipping. The Dillon sends out a car daily of \$50 grade and the Coriolanus a car a week of mill ore. A crosscut is being driven at the 500 level of this mine to cut the extension of the Ajax vein.

H. P. Reiton, operating blocks 26 and 27 of the Bonanza King, on Gold hill, Cripple Creek, is building ore bins and will begin hoisting ore this week from the recent strike on the property.

Lessees Best & Hanson, operating the Zoe, on Beacon hill, Cripple Creek, have resumed sinking and will sink an additional 75 feet to cut a station.

Machinery is to be installed by the Hildebrand Co. on Grouse mountain, near Cripple Creek. The shaft of the Hildebrand is down 400 feet.

The Blue Flag mine of Raven hill, Cripple Creek, is being retimbered and machinery will be put in.

The Santa Rosa G. M. Co. has granted a lease on its Belle City claim on Guyot hill, north of the El Paso group, to F. Case of Cripple Creek for two years at 20%, the lease requiring sixty shifts a month. This claim has a shaft down 100 feet.

The Ella mine, at Cripple Creek, has resumed with E. Hawk superintendent.

The Gold Temple G. M. & L. Co., leasing on the west block of the Gold Sovereign, at Cripple Creek, shipped two carloads of \$40 ore from the 650-foot level last week.

The lessing company operating the C. O. D., up Poverty gulch, Cripple Creek district, found it impossible to lower the shaft to 900 feet, on account of water, and are drifting at 850 feet.

The pump at Stratton's Independence, Cripple Creek, has been lowered to 1400-foot level and is in place. The water column is being lowered, but so as to not interfere with the hoisting of ore.

Osborne & Clements, on the Tornado of the Elkton Co., Cripple Creek, made output of 200 tons in January of ore running \$50 per ton.

W. Wilson, lessee, has begun work on a block of ground on the Gregory, near Cripple Creek.

The Mary McKinney M. Co., Cripple Creek, has opened up the No. 2 vein in the third level, showing 4 feet wide, assaying three ounces gold.

The Post says the gold output for Cripple Creek district during the month of January amounted to \$1,943,800, and the tonnage 59,905—a reduction from December, when the output was slightly abnormal on account of annual clean-ups.

Plant.	Tons.	Value Per Ton.	Gold Value.
Portland.....	7,000	30	\$210,000
Economic.....	3,150	27	85,000
Aequa.....	1,600	5	8,000
Dorcas.....	2,800	35	98,000
Telluride.....	2,300	20	46,000
Standard.....	12,000	25	300,000
Colorado City.....	9,000	25	225,000
Union.....	9,500	23	218,500
Smelters.....	12,555	60	753,300
Totals.....	59,905		\$1,943,800

The Telluride mill at Colorado City is increasing its capacity to 200 tons per day. Roasters are being put in at the Dorcas and its capacity will be increased to 200 tons daily.

Manager C. W. Knox of the Laura Lee, at Cripple Creek, under bond and lease to Boston men, will resume this week. A payment of \$5000 has been made on the bond. The main shaft is down 130 feet and will be sunk to 1000 feet. The Laura Lee claim adjoins the Addie C. on Mineral hill.

Manager C. Redpath of the Friday Leasing Co., operating the Friday claim on Tenderfoot hill, Cripple Creek district, says they are drifting on the 200-foot level to cut the extension of the Hoosier shoot.

G. L. Keener, manager the Mary McKinley mine at Anaconda, has been granted a two years' lease on the Sunset-Eclipse mine at Cripple Creek. The tunnel on the east end of the property will be driven ahead to prove the course of the vein and a new shaft will be sunk.

Lessee Price, working on the Flower of the West mine on Squaw mountain, near Cripple Creek, is driving a tunnel into the hill and has cut several veins, one of which is being drifted on.

Lessee Grant & Co., at work on the Currency claim on Beacon hill, Cripple Creek, have cut ore at a depth of 90 feet, the vein showing 2 feet wide and assaying \$15 in gold.

Lessees Wynkoop & Co., Cripple Creek, operating the south end of the Little Bessie under lease, have the shaft down 210 feet and will sink to 400 feet.

The Gold Dollar Con. Co. has granted a lease to C. Tillery and S. Camp on the ground north of the Gold Dollar shaft

and south of the south sideline of the Zoe. They will go to a depth of 500 feet.

A steam plant of machinery is being installed on the Henry Adney claim on Beacon hill, below the Old Gold and the C. K. & N., Cripple Creek, by M. B. Burke & Co., lessees.

The Mutual M. Co., operating a lease on the Amanda property at Windy Point, Cripple Creek, have the main shaft 200 feet deep and are driving south, cutting through a basalt dike to catch the wall when drifting will begin.

The Forepaugh G. M. Co. has granted a lease on the north 400 feet of its Forepaugh claim, Cripple Creek district, to J. R. Dray for four years. The Forepaugh is on Squaw mountain, adjoining the Alhambra on the south. The lessee will sink a shaft.

L. Montaigne & Bros., operating block 8 of the school section northeast of Cripple Creek, have resumed sinking on their lease and will go down to 550 feet. They are drifting in the 450 foot level.

The Sunset-Eclipse Co. has granted a two-years' lease on its entire group, Cripple Creek district, to G. L. Keener, who will drive the tunnel on the east end of the property to prove up the course of the vein and then sink a working shaft. The Sunset-Eclipse has been developed to a depth of 500 feet by a shaft and several levels.

E. Gortner, operating the Mollie Kathleen mine, on Tenderfoot hill, Cripple Creek, is driving a raise on pay ore from the 700-foot level and getting values of \$65 per ton. Bad air prevents taking out rock enough for shipping.

The United G. M. Co. has a lease on the upper level of the Deadwood, Cripple Creek district. There are three other sets of lessees working.

The English-American G. M. Co. has taken a sub-lease on block seven of the school section, Cripple Creek. At a depth of 175 feet they are drifting to strike the ore shoot opened up on the 90-foot level.

IDAHO.

BINGHAM COUNTY.

The Idaho Gold Dredging Co. of Salt Lake City, Utah, has organized and will begin operations this week along the banks and shoals of the Snake river, between Shelley and Blackfoot. T. Geddes of Tonic, Utah, is president, with W. C. Bogue, S. O. Snyder, S. V. Shelp, F. B. Stephens directors.

BOISE COUNTY.

The Ebenezer mine, near Placerville, under bond to Southworth & Co., reports an 18-inch shoot of gold ore in the shaft at a depth of 105 feet.

ELMORE COUNTY.

J. L. Hill & Co. of New York City have bought the Kimberly and Jewel group on Bear creek, in Marshall Lake district, for \$65,000. R. G. Law of Boise is manager.

The Rose Etta M. & M. Co. of Salt Lake City has incorporated to operate the Planet-Rose Etta group in the Bear Creek mining district; W. A. Potter, D. H. Wenger, M. R. Brothers, L. P. Palmer and W. L. Lowry, directors.

IDAHO COUNTY.

Three feet of \$60 free-milling ore is reported in the north drift of the Wise Boy at Hump by Manager W. Moore. A. W. Crittenden of Republic, Wash., is foreman, and has thirty men getting out ore from the No. 1 level and drifting north and south in the lower level. A raise from the north drift, No. 2 level, will be driven to No. 1, which will give stoping ground enough to keep the 10-stamp mill in operation.

The Noisy Boy G. M. Co. has incorporated at Spokane, Wash., F. P. O'Neill, R. Strang, D. S. Prescott, A. D. Coplen, J. E. Meyers, to operate the Noisy Boy Nos. 1, 2 and 3, in Thunder Mountain district, on Sugar creek, 20 miles south of Thunder Mountain.

LATAH COUNTY.

The Idaho Mica M. Co. the last two weeks have taken out four tons of mica from their claims on Bear creek, 13 miles northeast of Troy. The vein is said to be 30 feet wide and samples of mica run from 2x2 to 10x12 inches in size. The owners are S. G. Kitchen and L. M. Steelsmith of Troy and P. J. Scallon of Coeur d'Alene City.

NEZ PERCES COUNTY.

J. M. Edwards, president of the Gold Crown M. Co., which owns a group of prospects on Snake river, near mouth of Grand Ronde river, says they have opened up free-milling gold ore assaying \$20 in a 4 foot ledge cut on the surface. The ledge has been uncovered by test pits for 300 feet.

C. M. Stearns is operating a group of claims on Clearwater river, above Kamiah, and near the Jack-Bettman group. Near the Jack-Bettman group the Lav-

erty group is being developed by the Plattsburg-Idaho M. & M. Co., recently incorporated by Laverty Bros. and J. C. Bridwell of Kamiah. Two tunnels have been run on the ledge, one 430 feet and the other about 210 feet, besides a shaft 100 feet deep. Below this is the Alto-Idaho M. Co. mines of A. H. Pardee, Philadelphia, Pa.

G. A. Neerhood, J. A. Husebye and W. L. Kilkinson of Lewiston have bought eighty acres of marble quarries 3 miles above Wild Goose rapids, on the Snake river, on the Idaho side, and will develop them. The quarries are above those operated by A. Vinson of Walla Walla. There is also a body of granite suitable for building stone.

SHOSHONE COUNTY.

W. Dahl of the Chicago & Pierce M. Co., says they have 320 acres of placer ground on Oro Fino creek, 4 miles above Pierce City, and will build a ditch 28 miles long and put in an hydraulic elevator. Dahl, with S. S. Johnson, W. J. Harris and G. M. Williams have organized the Chicago & Spokane Placer M. Co. to work 800 acres on Oro Fino, Canal and Rhodes creeks, near Pierce. The Santiago quartz mine, 4 miles north of Pierce City, has a 12 inch vein and a 2-stamp water power mill in operation. A crosscut to be 700 feet long has been started on the Crescent. The Klondike at Pierce will resume in the spring and the 5-stamp mill increased to twenty stamps. The American Placer M. Co. will install an hydraulic plant to cost \$25,000 on Oro Fino creek.

Superintendent C. C. Smith of the Oro Grande mine, 12 miles from Pierce, says he has men at work crosscutting to the ledge, and will run drifts either way.

The Paragon M. Co., near Murray, is sinking the double-compartment shaft with two shifts, says Manager Stedman, and is down 75 feet. When the 300-foot level is reached a crosscut will be run. The bottom of the shaft is in quartzite. The Benton M. Co. was incorporated at Burkelast week, John and James Callahan, W. H. Smith, B. N. Hillard, T. Anderson, to operate a group of claims near Burke.

Work has been resumed on the Apex mine, north of Wallace. The tunnel, which tapped the lead, will be driven another 100 feet. In the spring power will be obtained from the Washington Water Power Co. to run an air compressor.

The New Jersey G. M. Co., which has bought the South Fork gold mines, 3 miles east of Wardner, on Gold Run creek, will put up a 10-stamp mill.

KENTUCKY.

LIVINGSTON COUNTY.

F. M. Barnard of Paducah, superintendent of the Pittsburgh Fluor Spar M. & M. Co., reports that a vein of high-grade lead ore has been struck in his mine near Smithland, on the Cumberland river.

MICHIGAN.

HOUGHTON COUNTY.

Superintendent Wilcox of the Mass Con. Copper Co., near Houghton, says, with one head stamping 260,000 pounds of copper a month are produced. There are 400 men employed at the property and the company has three drills in operation. Five additional drills will be put in.

The Mohawk, near Houghton, is stamping 900 tons of rock daily.

Near Houghton, the one head at the Atlantic mill is in operation, all the rock coming from underground, not taking any from the stock pile on the surface.

The superintendent's report for 1902 of the Victoria Copper M. Co., near Houghton, shows 5640 feet of openings made during 1902, bringing total openings to 20,299 feet; the two veins came together at the 15th level; dip of vein changed from 61° horizontal to 55°, bringing the shaft in the foot wall from 25 feet at the 13th level to 60 and 80 feet at the 14th and 15th levels, respectively. Owing to fact that shaft has been in foot wall, trouble was had with hanging wall of shaft, necessitating timbering the same below 14th level; 8th level was in stamp, mass and barrel ground. To 550 feet west of shaft 10th level was in vein of heavy stamp copper and in fine stamp copper to 700 feet. The 12th, 13th and 15th levels have been in stamp and barrel drifts. Copper-bearing part of vein in all levels varies from 6 to 40 feet.

Shipments of refined copper from the Lake Superior district are going forward rapidly and no metal is accumulating at the local smelters. The Lake Superior Smelting Co. has done a large business recently at both its Dollar Bay and Hancock plants, refining increased amounts of mineral from South Range mine.

Oscoda No. 5 shaft, near Houghton, resumed hoisting Feb. 2.

MASON COUNTY.

At the Quincy mine the incline shafts are down 6000 feet. The skips are being changed in shape, so the rock will not roll out where the shaft is flatter.

The Evergreen lode, where it is cut by the Butler tunnel in the Adventure mine, is 12 feet thick. The lode shows mass and barrel copper—masses ranging in weight from 100 pounds to a ton.

ONTONAGON COUNTY.

The Hamilton mine, adjoining the Norwich, near Ontonagon, will be reopened by Milwaukee and Gogehic interests.

MONTANA.

BEAVERHEAD COUNTY.

The Kent mines, near Bannack, are being worked under bond and lease to Butte men, with W. A. Butler superintendent. —Mathews & Peterson report a strike on the Blue Jay.

The July Flower mine, near Dillon, is bonded for \$20,000 to N. W. Pearson of Butte.

CARIBOU COUNTY.

The Northern Pacific R. R. Co. will develop its group of 1600 acres of coal land lying east of Red Lodge, where the fields of the Rocky Fork Coal Co. are being developed. H. Horn is manager.

CUSTER COUNTY.

C. E. Barnum of the Silver Top Coal Co., operating the coal lands near Garland, says the mine is 12 miles from a railroad. He will transport the coal to Garland by ten steel wagons, having 12-inch tires and a capacity of twelve tons each, hauled by a traction engine of 83 H. P. The mine is developed by two tunnels, the face of one showing a 5 foot vein of coal.

DEER LODGE COUNTY.

The Cable mine at Cable has been unwatered and development resumed with twenty men at work. At the head of Flint creek the Milwaukee Gold Extraction Co. has twenty men at work, says Superintendent G. H. Savage.

FERGUS COUNTY.

Superintendent C. F. Gadsen, the New Mines Syndicate, operating the sapphire mines at Yogo, says sixty-six men are at work; but operations will be enlarged the coming season.

JEFFERSON COUNTY.

It is reported a body of galena has been cut in the raise being driven to connect the lower tunnel with No. 2 at the Bullion mine, near Basln. The lower tunnel is in 1925 feet.

MADISON COUNTY.

F. B. Dickerson and C. C. Adkins are working the Atlanta lode of the Forre M. Co., on Mineral hill, near Pony.

J. King, owner of the U. S. Grant mine, near Virginia City, has resumed development.

Two 100 H. P. boilers are being installed at the Galena mine, near Sterling.

MISSOULA COUNTY.

The Dennemora G. & C. M. Co. has incorporated at Wallace, Idaho; B. Scott, E. Johnson, O. Nordquist, E. and S. Johnson, to operate a group of six claims near Saltese.

POWELL COUNTY.

C. Hartman and T. Cooney have a bond on the Ophir placer claims below Ophir, comprising a strip 2 miles long and $\frac{1}{2}$ mile wide.

SILVER BOW COUNTY.

The Butte Reduction Works, an old and antiquated smelting plant, will be abandoned and all the ore from the Clark mines will be treated at the new Washoe smelter in Anaconda. That change is to go into effect on May 1.

NEVADA.

ELKO COUNTY.

Manager A. Carlson of the Deer Creek mine, near Charleston, says he will put up a stamp mill of fifty tons daily capacity. The property is 45 miles northeast of Tuscarora. The ore runs \$20 in gold.

LINCOLN COUNTY.

At the Iris claim at Deer Lodge, owned by Moody & Dameron, the shaft is down 100 feet in 6 feet of ore assaying \$20 in gold.

J. B. Gilbert & Co. are developing a turquoise mine in the Hardscrabble mountains at Crescent.

The double-compartment shaft on the Green Monster mine at Sandy is down 175 feet and in ore. The mine is owned by the Hearst estate and F. O. Wilkinson is superintendent.

C. Gracey has put in a hoist at the Techaticup mine at El Dorado canyon, and will sink the shaft, which is down 80 feet below the tunnel level, to 500 feet.

In the Quartette mine at Searchlight the 600-foot station is finished, the lead crosscut and drifting begun. The cross-

cut at this level shows 14 feet of ore. The storage reservoir is finished. Work to connect the fifth and sixth levels has been started.

J. W. Tuck, working a group of claims on Spirit mountain below Searchlight, reports opening up a body of free gold ore. The vein was cut in the tunnel and 11 feet of ore exposed. In the shaft 3 feet of ore were cut. The mines are near the top of the mountain and 7 miles from the Colorado river.

LYON COUNTY.

The Nevada Reduction Co. are increasing the capacity of their cyanide plant at Dayton.

The mill at the Como-Eureka mine in Como district is in operation, using electric power from the plant at the Douglas dam on the Carson river.

NYE COUNTY.

The Templar group of three claims and a fraction adjoining the California-Tonopah on the west, near Butler, is being developed by Superintendent L. L. Patrick, who has let a contract to sink 200 feet. This property is owned by Mecham & Co. of New York.

The third shipment of ore from the mines of the O'Meara-Lynch Co. at Lone mountain, near Butler, was made to the smelter at Salt Lake City last week, making ten carloads to date. The ore nets the company \$3000 a car.

Manager L. L. Patrick has begun work on the Pinto group of fifteen claims adjoining the Newhouse property, near Butler. Four veins have been located on the Pinto group, and surface croppings show values in gold and silver.

Superintendent G. Jones of the Pactolus M. Co. reports a vein of gold-silver ore struck on the Pactolus mine, 50 miles north of Butler.

The Colehan M. Co., on Gold mountain, near Butler, will let a contract for sinking and timbering a double-compartment shaft to a depth of 200 feet.

A contract has been let to sink a shaft to 200 feet on one of the three claims of the Temple-Syndicate M. Co. of New York. The ground adjoins the California-Tonopah on the south. L. L. Patrick is superintendent.

H. M. Hashrouck, A. McIntyre and G. Kernick, operating northwest of Gold mountain and 6 miles from Butler, report having opened up a ledge of quartz on the surface, in porphyry, carrying \$30 gold, with silver and copper.

The tunnel being run on the Tonopah G. M. Co.'s group at Gold Mountain, near Butler, is in 120 feet, and a vein cut assaying \$47 in gold and silver. The tunnel will have to be run 130 feet to tap the ledge which crops on the surface.

At the Colehan Co. claims at Gold mountain, the shaft is down 40 feet in porphyry. Last week the company let a contract to sink a double-compartment shaft to a depth of 200 feet.

W. D. Nelligan, owning a group on Lone mountain near Butler, says on one claim a shaft 50 feet deep has been sunk and a ledge 4 feet wide exposed, which assays \$25 gold and silver.

The main shaft at the Tonopah-Union, near Butler, is down 125 feet and in ore. A whim is in operation and 2 feet a day are made.

Assayer T. F. Niland, at the Newhouse mines at Hannapah, says he has found by analysis that their ores carry platinum up to \$200 a ton. It occurs as platinum-diarsenide, in minute cubes or cubo-octahedrons, with a metallic luster. This is the only known native compound of platinum (says Dana's Mineralogy). Its occurrence has also been noted in the Ramler mine at Grand Encampment, Wyo.

WASHOE COUNTY.

The Slip mine at Olinghouse is extracting ore from a 6 foot vein and the tunnel is in 620 feet. There are sixty-five men working in the mines at Olinghouse and three mills running.

NEW MEXICO.

COLFAX COUNTY.

Drilling is begun by the New Mexico Oil Co. at Raton, on the McKown ranch.

SANTA FE COUNTY.

President Sopers, the Bayard M. Co., owning placers at Golden, says the mill will be operated to make a test of gold-bearing cement beds occurring in that vicinity.

SOCORRO COUNTY.

A. B. Finch and C. T. Brown have bought the Ida Hill group of the Ida Hill M. & S. Co. at Kelly, and will consolidate with the Graphic group of mines.

OREGON.

BAKER COUNTY.

Superintendent McEwen of the California mine, near Sumpter, is raising from No. 5 tunnel to No. 4, to complete the

system of chutes for stoping the upper levels through the Blacksmith tunnel.

Manager J. K. Romig of the Sanger mine, near Baker City, says the Walla Walla Development Co., operating the Sanger mine, has been reorganized. He has twenty-five men at work and will reopen the property.

Manager J. M. McPhee of the Golden Wizard mine, Deer Creek district, near McEwen, is putting in development machinery and a 100-ton concentrating plant will be installed in the summer. The shaft will be unwatered and sunk 155 feet deeper. J. Murrin is superintendent.

Manager McPhee, of the Golden Wizard mine, near Sumpter, says the shaft has been unwatered, and sinking resumed by contractor J. Murrin, who will sink to the 300-foot level. The hoist being put in will have a capacity of 1200 feet. The station pump, to be installed at the 140-foot level, will raise 1000 gallons per minute 500 feet.

The Standard G. & C. M. Co. will build a mill at their mines near Sumpter, says Z. Houser, one of the owners. The work in the lower tunnel of the Standard continues and shipments of cobalt concentrates are being made.

Twenty stamps are dropping at the Golconda, near Sumpter, crushing 100 tons of ore daily.

The Highland G. M. Co. has bought the El Dorado group on the mother lode system, near Sumpter.

The Greenhorn G. M. Co. has been incorporated to operate the Worley mine, located in the southern part of Greenhorn—J. Fawcett and W. Killen.

The Little Cracker G. M. Co. has incorporated—E. Butze, R. L. Turner, D. L. Willard—to operate on Little Cracker creek, near the Cracker-Oregon mine, near Sumpter.

Superintendent Jackson, of the Killen, Warren, Stewart Co.'s Cracker-Eagle mine, near Sumpter, reports having cut through the ledge which is 105 feet wide at a depth of 100 feet, showing 42 feet of milling ore which runs \$3 per ton. The crosscut tunnel is in 210 feet.

The Bannock Burn or Knapp group of four claims, 8 miles northeast of Sumpter, has been sold to the Highland G. M. Co., N. J. Sorensen, president.

GRANT COUNTY.

The Oregon M. & D. Co. has incorporated at Baker City to operate the G. Izly and Red Cloud groups, near Granite and adjoining the La Bellevue mine; J. L. Rand, F. Davis, H. S. McCallum, J. T. Donnelly. H. L. McClane is manager.

Manager T. B. Carsons of Liberty, Wash., has resumed work on the Milwaukee placer, 3 miles down Granite creek from Granite.

W. Cleaver, operating on the Copper Ridge group, adjoining the Standard and the Willie Boy, near Quartzburg, says they have opened up the extension of the Standard's cobalt vein, showing values in gold and copper with the cobalt.

It is reported that the Geiser-Hendryx Investment Co. has a bond on the Cougar mine, near Granite.

SOUTH DAKOTA.

CUSTER COUNTY.

The Interstate G. M. & M. Co. has incorporated to operate a group of claims near Custer, adjoining the mines of the Grantz G. M. Co. W. H. Godden of Emmetsburg, Iowa, is manager.

A pocket of ore carrying tellurides was found last week on the Roosevelt group of the Grantz G. M. Co., near Custer. A drift was started west in the shaft and is in ore 20 feet.

The Cuyahoga M. Co., whose mines are 12 miles east of Custer, will resume development work. They have been shut down while putting in an air compressor and drill pumps. They are sinking a winze in the breast of a 600-foot tunnel on a vein of gold ore 20 feet wide, assaying \$10 per ton. In driving this tunnel they crosscut a vein of tin ore. As soon as the mine is opened up a wet crushing cyanide mill will be built to recover the gold values. The company is composed of Cleveland, O., men, and they have 400 acres of lode claims and millsite.

One hundred and nine samples recently taken by the Grantz G. M. Co. on the Roosevelt group, near Custer, not including concentrates, gave an average assay value of \$40 in gold. Some of the ore is schist veined, with quartz and mica, and the Interstate G. M. & M. Co. has begun development. There are 195 acres. A sawmill is on the ground and cutting lumber for a shaft house, office building and mine timbers. T. P. McLaughlin is superintendent. The Gladiator Co. is developing the Gold Fish group of claims, and is taking out ore. The company will put up a mill.

LAWRENCE COUNTY.

The Home M. Co. has resumed after a

shut down. A shaft is being sunk on City creek, Deadwood, following a ledge of auriferous pyrite, carrying copper sulphide. A steam hoist will be put up.

A quartz mill will be installed by the Lucky Strike M. Co., near Roubidax, for their Box Elder mine. The mill will have a daily capacity of twenty-five tons.

Groshong Bros. of Galena are opening a gold bearing vein 40 feet wide, 1½ mile southwest of Roubidax.

On Annie creek, 8 miles southwest of Deadwood, the University and Aksarben companies are developing their claims and have 500 tons of siliceous ores on their dumps. The management of these companies believe the ore reserves in the mine will warrant mills in the spring. Sixteen men are employed.

Three hundred employees of the Golden Reward smelter at Deadwood have gone on strike because of one man being laid off. About 700 others will be idle, the company having decided to close two of its mines.

The Pennsylvania G. M. Co. is developing its group on Deadwood and Rutabaga gulches, near Central City, and are blocking out shipping ore. They have one vein 14 feet wide opened to a depth of 300 feet and for 1000 feet on its course mill tests have shown an average value of \$30 a ton. It carries sylvanite and marcasite. Building and mining operations are under way on the group of the Gladiator Con. G. M. & M. Co., adjoining the Pennsylvania. The Big Four M. Co. is driving a crosscut through the phonolite, on its property across Deadwood gulch from the Pennsylvania and above the Gladiator. It has a steam hoist and is putting in an air compressor.

Secretary D. N. Heizer of the Spearfish G. M. & R. Co., near Deadwood, says the output for January was 6000 tons and the grade of the ore higher than that of any preceding month. During December the ore averaged \$5 10 in gold per ton, and in January \$7. The cleanup for the first half of the month resulted in a gold bar 900 fine and weighing 948.87 ounces. The plant is treating 200 tons of ore per day. It is the intention to bring the plant up to its full capacity of 275 tons as soon as other stopes are opened in the mine.

The Yellow Jacket G. M. Co. of Rapid City is at work on 140 acres of mineral land near Custer Peak.

PENNINGTON COUNTY.

The National smelter, at Rapid City, of the Horseshoe M. Co., is handling 300 tons a day. The Horseshoe Co. is supplying the ore from the Lucile and Mark Twain mines, in Lawrence county, shipping over the Elkhorn railroad. Flux is from Fergus county, Mont., where the company owns an auriferous pyrite mine.

TEXAS.

HARDIN COUNTY.

C. H. Markham has bought the ground of the Beaumont & Saratoga O. & P. L. Co., in the Saratoga oil field, near Saratoga, for \$320,000. The property of the company consists of five tracts of land, containing 819 acres in all. There are two flowing wells yielding oil at present.

UTAH.

BEAVER COUNTY.

The Wild Bill Co. shipped a car of high-grade ore from the Burning Moscow, near Milford, last week.

BOX ELDER COUNTY.

The Irene G. M. Co. has incorporated; P. A. H. Franklin, J. A. Van Pelt, A. D. Beeman, T. Botkin at Salt Lake City to operate the Irene Nos. 1 and 2, Chief, Major, Atlantic and Oregon at Park valley.

GRAND COUNTY.

President Ray of the Westwater Oil & Asphaltum Co. at Westwater says operations are begun on the refinery and several oil drilling rigs will be put to work.

IRON COUNTY.

The mill of the Johnny M. Co. at State-line is in operation.

JUAB COUNTY.

Work on the May Day mill at Eureka is stopped temporarily.

At the Little Chief mine, near Eureka, they are stoping on a 3 foot body of lead-silver ore, and a carload of sorted ore was shipped this week.

Work in the Northern Spy shaft of the Carisa at Tintic has been discontinued until the steam hoist at the Carisa shaft has been moved over. Ten days' work after the change is made will complete the connection with the Sioux-Ajax tunnel.

The management of the Centennial-Eureka at Tintic will sink the shaft 500 feet deeper.

PIUTE COUNTY.

It is reported the Trapper's Pride mine

of the Madsen G. M. Co., at Kimberley, has been bonded to Eastern men for \$150,000.

SALT LAKE COUNTY.

The strike on the 1300 foot level of the Brooklyn of the Bingham Con. Co., on the Dalton & Lark side, near Bingham, shows in the crosscut 24 feet of sulphide ore, carrying twenty ounces silver, some gold and 4% copper. Several carloads have been sent to the smelter.

The fourth furnace of the United States M. & S. Co., at Bingham, was blown in last week and 181,362 pounds of pig copper were shipped, says Manager Holden.

W. James, superintendent of Black Rock, near Salt Lake, says he will sink the main shaft an additional 100 feet.

The cost of producing copper by the Utah Con. Co. at the Highland Boy at Bingham is said to be 7 cents per pound, deducting precious metal values of \$2 to \$2.50 per ton from the cost of treatment and allowing a recovery of 69 pounds of copper to the ton of rock from the run of ore, which assays 4% in copper. Additional ore bodies have been opened up and it is proposed to double the capacity of the works. This will require also another aerial tramway for the transportation of the ore.

A cave-in in one of the stopes of the Old Telegraph mine in Bingham last week partially wrecked the house of J. Johnson, a miner, killing two of his sons.

It is reported that the examination of the property of the Boston Con., at Bingham, by R. Nichols of London, is to advise whether concentration or smelting will be the best treatment for their ores.

SEVIER COUNTY.

It is reported that Lellich & Mork of Salt Lake City have bought a group of claims on the copper belt in Deer Creek district, near Richfield, east of the Butler-Beck.

SUMMIT COUNTY.

Construction work on the zinc plant at Park City is completed and it is expected the plant will be in operation by Feb. 20, says Manager A. L. Dickerman. The plant will handle 80 tons per day, which capacity is to be increased to 100 tons daily. It is expected that zinc ores from other camps in the State will be treated at this plant.

A snowslide at Park City, Jan. 28, wrecked the Quincy mine shafthouse, carrying the structure into the valley below. J. Gaffney, engineer, E. J. Colter, station tender, and C. D. Frink, fireman, were killed and nine others injured. Assistant Manager E. Bamberger says repairs will be made and work resumed.

TOOELE COUNTY.

Manager G. H. Dern, the Con. Mercur M. Co., reports the following results at the new tailings plant on sluices portion of it. The tailings treated assayed \$1.29; after treatment, 41 cents, an indicated extraction of 68.5%. This result was obtained from the sluices, the sands submitted to the usual process not having been accounted for, and they were entirely free from slimes when placed in the leaching tanks. The only difficulty experienced in making a high saving of the values in Con. Mercur ores has been the large percentage of slimes accompanying tailings. These would clog the tanks and prevent the proper percolation of solution. The process now being tried is effecting a separation of the slimes from the sand.

Manager J. Dederichs, the Black Diamond Co. property at Stockton, says on the 100-foot level the vein has been opened up for 60 feet, showing 14 feet of ore carrying \$7 gold, 24% lead and fifteen ounces silver. The Honerine tunnel will tap the ledge at 500 feet below the surface, and enable the Black Diamond to prospect its territory without hoisting.

G. Moore, manager of the Sunshine Co.'s mines at Sunshine, Camp Floyd mining district, says a slimes plant similar to the one in operation at Mercur is contemplated for Sunshine.

UTAH COUNTY.

In Silver Lake district, near American Forks, Superintendent J. Cleghorn reports uncovering a vein of copper pyrites 20 feet wide and assaying 12%. This property has been bonded by an Eastern company for \$40,000. Shipments of ore have been made from the Milkmaid. A mill and an electric road from American Forks to Deer creek are proposed by the company bonding the Cleghorn group. It is reported the Miller Co. will sink a double-compartment shaft to 1000 feet.—The Pacific G. M. & M. Co. has had men at work all winter. They are running a tunnel to tap a vein which on the surface assays eighty ounces silver, 27% lead, with gold and copper values. The tunnel is in 320 feet.

WASHINGTON COUNTY.

Manager G. Snyder of the Dixie copper

group at St. George says the smelter is in operation, and the main shaft will be sunk below the tunnel level.

WASHINGTON.

CHELAN COUNTY.

T. Maloney, superintendent of the Chelan T. & S. Co., says: "Our company is building an electric railroad from the mouth of the Chelan river, on the Columbia, to Lake Chelan, 3 1/2 miles. The company will have steamboats from there to Railroad creek, 45 miles up the lake, where it will build a smelter and copper matting plant of 300 tons daily capacity. From the smelter a narrow gauge steam railroad will be built 10 miles to the Holden mine, with spurs to properties."

FERRY COUNTY.

J. W. McCann, who has a lease on the North San Pol, near Republic, has begun development work, and will sink the shaft an additional 100 feet to the 225-foot point.

W. G. Madison, president Bodle M. Co., near Republic, says twelve men are at work in the mine, drifting on ore on the No. 3 level and driving ahead No. 4 tunnel. A survey of Toroda creek has been made for power to run a mill, which will be installed at the Bodle mine.

OKANOGAN COUNTY.

A. M. Riste and G. Bowers have men at work on the Ruby claims, on the east slope of Mount Chacapa, south of the Golden Zone, near Loomis.

A strike of ore carrying values in gold and copper is reported in the shaft of the Grant mine at Chesaw, bonded to W. T. Mendenhall & Co.

STEVENS COUNTY.

The discovery of uranium is reported in claims owned by Grutts & Mulligan, in O'Toole mountain, 12 miles from Bossburg. The uranium is associated with other minerals.

The Silver Butte mine on Deep creek, near Northport, has resumed shipments of silver-lead ore. C. C. Knutson is manager. The coke situation is assuming a more favorable aspect, according to local smelter men, and it is expected the entire plant of the Northport S. & R. Co. will be in operation by March 1. Four blast and two calcining furnaces are running and handling 1000 tons per day.

The Pearl G. M. & M. Co., operating the Pearl group near Republic, is driving a tunnel, which is in about 45 feet and has crosscut a 12-foot vein of quartz, says superintendent Howe. The Pearl group is west of the Zala M. and has a parallel vein which crops on three claims of the group. The Howard Fraction carries the cross-lead and there is a shaft down on it 50 feet, showing shipping ore.

The fourth furnace at the Northport S. & R. Co. plant at Northport was blown in last week, and it is expected a fifth will be added by March 1st.

WYOMING.

CARBON COUNTY.

The Osceola mine, adjoining the Ferris-Haggerty of the North American C. Co., near Rudelaha, has been sold to New York men represented by C. F. Fishback, of Rawlins, Wyo.

FOREIGN.

AUSTRALIA.

Additions to the Mount Lyell Co.'s reduction works now enable the whole of the crude ore treated at No. 2 plant, where two furnaces are in operation, treating 1000 tons a day, to be smelted without the use of coke, making an estimated saving of \$100,000 a year. The same economy is being applied successfully to the two furnaces at No. 1 plant, the ore in one of which is being operated without coke and the other partly so. Another change recently made is in the reduction of the amount of hot air used in the furnaces. Where twenty-four men were formerly employed in firing the hot-air stoves the work is now done by six.

The Lake View Consols is reported earning a profit of \$35,000 per month. In the mine prospecting on an extensive scale is in progress in the lower levels of the Associated with encouraging results.

WEST AUSTRALIA.

Great Boulder Main Reef: Coolgardie field reports, December returns, 1402 tons crushed yielded 1119 ounces gold; average assay value of ore crushed, 17 dwts; extraction, 92%; mill shut down for six days overhauling plant. The main shaft has been sunk to 140 feet below the tenth level and crosscut started both ways at level No. 11.

Great Boulder Proprietary Gold reports crushing returns for month of December: At sulphide mill and by cyanide,

including 908 tons tailings, 8800 tons of ore crushed, yielding 13,879 ounces gold; at battery, 500 tons crushed, yielding 517 ounces; concentrates, 45 tons crushed, yielding 225 ounces; at Great Boulder No. 1 battery, nil. Total yield, 14,621 ounces; estimated value, £14,975.

BRITISH COLUMBIA.

An assay made by the Provincial Mineralogist indicates that the black sand of Carib o placer claims carries values in gold, platinum and osmiridium.

F. Griffith reports a strike of ore on his Westmount claim, on Ten Mile, near Sandon.

J. F. Collom, manager Arlington mine, near Slocan, is making arrangements for a mill to treat the ore of that mine. He says the process will be a combination of the electro-magnetic and cyaniding.

There are 800 men employed in Rossland camp—Le Roi has 360. War Eagle and Centre Star mines 312, Kootenay 40, Josie 50, White Bear 15, Velvet 20.

A zinc concentrator will be erected in the Slocan, says T. Jones, representing the Iola, Kas, smelter, who has been investigating the situation in the district about Slocan.

Manager Watson of the Fisher Maiden M. Co., at Silvertown, says three carloads of ore were shipped to the smelter at Trail last week. Assays showed 169 ounces silver, 6% lead and 15% zinc. The smelter fines 50 cents a unit for ore carrying over 8% zinc. With this fine and the \$13.50 charges from the mine to the smelter, the company netted \$598.11 from the last 22-ton shipment.

The East Crow's Nest Coal & Coke Co., composed of Spokane, Wash., men, have begun development work in the Crow's Nest Pass district. Vice-President A. L. Davenport says the company has bought 522 acres of coal land on the north side of the Old Man's river, 6 miles east of Frank, on the line of the Crow's Nest Pass Railroad, which crosses their property 200 feet from the main shaft. A sidetrack is built to this shaft. The river forms the south boundary of the company's land, a bluff on the north side of the stream exposing nine seams of bituminous coal from 3 to 9 feet in thickness. The shaft is down 480 feet on a 5 foot seam.

J. Lineham of Okotoks, Alberta, says of his company's boring operations in the Kootenay oil fields that oil of good quality was struck at 1100 feet. The oil being tapped spouted for some time, but finally diminished, owing to the influx of water. The drill is stuck at a depth of 1200 feet. It is proposed to construct a pipeline from the oil fields to Macleod. The company have control of one and a half section of land and will make further tests.

Manager W. Walde, one of the owners, has men at work on the Queen property on Sheep creek, near Salmo. They have the use of the Yellowstone mill.

Two stamp mills will be installed in Camborne camp, near Rossland. One on the Eva group, operated under bond by the Calumet & Hecla Co., will be a 10-stamp mill. The Oyster Criterion group in Camborne will have a 10-stamp mill.

The Velvet mine will put in more baby machine drills, says Manager Gray.

The Granby Con. M. S. & P. Co. will equip a machine shop to do all the repairs, constructing, etc., required about the mines.

"The results with the experimental plant installed to test Rossland ores with the Elmore process of oil concentration are satisfactory up to the present and a plant to work on a commercial scale will be built," says H. H. Claudet, metallurgist the Canadian Ore Concentration Co. "Samples from the Slocan, Similkameen and other districts have been treated. In one case, from a copper ore containing a slight amount of silver, there was extracted 80% of the copper and 71% of the silver. In another case, a gold-copper ore, 81% copper and 71% gold was recovered. In the third test, a gold-copper ore, the percentages of recovery were 76% in copper and 83% in gold. A point in connection with these tests is that percentage of recovery is uniformly greater where a plant is in operation than is the case with mere tests. For one test we prefer ore in lump, as the crushed product is exposed to oxidation, and the results secured not so satisfactory."

The Ivanhoe, at Slocan, has closed a contract to ship zinc concentrates to Iola, Kansas.

F. H. Oliver of Spokane, Wash., manager of the Morrison mine, in Deadwood camp, near Rossland, has contracted with the smelter for ore shipments, and operations at the mine will be resumed. A spur will be built from the Canadian Pacific to the mine.

Mining in the Kootenays and the Boundary districts is being hampered by the shortage in the coal and coke supply. The smelters have but a portion of their furnaces in blast. The coal companies at Fernie, Crow's Nest and Michel are mak-

ing coke, but their capacity is insufficient to meet the entire demand.

The Union Jack group of the Active G. M. Co., at Ymir, will install electric power and electric drills, says Superintendent Cameron. Last week, in tunnel No. 2, at a depth of 60 feet and 165 feet in, 4 1/2 feet of galena ore was struck. The company intends in the spring to install a sawmill to cut timber for shipment to the Northwest.

CUBA.

The iron mines of the Province of Santiago employ 4000 men. Americans employ 125 men at 85 cents per day in manganese mining. Some copper mines are being reopened.

KLONDIKE.

It is reported that a lower pay streak has been found on El Dorado creek, the former streak resting on a false bedrock. It is now thought there may be several pay streaks in the gravel beds of this stream, the working of which will give new life to the district about Dawson, as other creeks will be prospected for lower pay streaks.

KOREA.

F. L. Cole, superintendent of exploration of the Wunsan G. M. Co., near Chemulpo, writes: "The Wunsan mines are 350 miles south of Seoul. As yet the workings are not deep. There are 7000 natives employed who receive 25 cents per day. There are seventy white people at the mines, mostly Americans. The mill in which the ore is treated has 120 stamps and an additional 80 stamps are being put in. There is a cyanide plant." Under Cole's supervision are thirty-five prospects and one mine, employing in all 700 men.

MEXICO.

CHIHUAHUA.

M. Wicks and C. E. Delno of Austin, Tex., have bought the famous Sierra Rica mine and the Amella adjoining, making seventy-three pertenencias and several thousands acres of land surrounding them. At 300 feet depth in the Sierra Rica is a vein 2 meters wide of ore which runs \$100 per ton in silver. The group is in the Ojinaga district.

M. Wicks and C. E. Delno of Austin, Tex., have denounced 250 pertenencias of mineral ground in the Santa Eulalia camp.

P. Ginther, manager the Encinillas mines, 45 miles east of Santa Rosalia, says work has begun on the 80-ton smelter, with 200 men employed in the mine and plant. The shaft, down 320 feet, is being sunk.

Manager S. N. Dedrick, the Sierra Boluda mine, near Chihuahua, says he has 700 feet of development work done. The workings show an ore body 10 feet wide, averaging \$10 gold per ton, with silver to pay for mining and milling. On the Cinco de Abril mine, 15 miles distant, Dedrick has let a contract for 150 feet of work. The mine consists of fifteen pertenencias on the vein, which is 40 feet wide. The ore is free milling gold and silver.

LOWER CALIFORNIA.

(Special Correspondence) — The mine owned by the Viznaga G. M. Co. at Alamo has been boarded up and all work stopped. A strike was recently made and it is reported the managers wish to confer with the stockholders as to the plant needed. H. M. Russell of Los Angeles is president and F. E. Russell is superintendent at the mines. Considerable development has been done by this company and former owners. Recently a drift was run from the shaft and in 25 feet a 7-foot body of ore was cut, 18 inches of which is rich, while 600 pounds run through the mill necessitated a clean-up. The rock is a decomposed brown ore and is very soft.

The Aurora M. & M. Co., on the same vein, has been working and producing about \$20,000 per month. This is owned by Douglass-Lacy Co. of New York. Ensenada, Jan. 30.

SONORA.

The Palomitas claim, on the same ledge as the Lucky Tiger, near the Pilares de Teras silver mines, has been bonded to H. F. Smith and C. M. Stover of Philadelphia, Pa., for \$100,000.

The Cerro Escalado Gold Mines Co., near Nacosari, 100 miles south of Douglas, consists of a group of twenty-six pertenencias and a millsite. It is the intention to erect a 10-stamp mill this spring.

SIBERIA.

A St. Petersburg dispatch states that deposits of platinum have been discovered by diggers on the River Gusseva, a tributary of the Issa, in western Siberia. Government officials have gone to the district.

PERSONAL.

J. D. YOUNG, of Chicago, goes to Chihuahua, Mexico.

W. G. KING is Professor of Metallurgy at the State School of Mines, at Golden, Colo.

C. E. KNOX, manager Montana Tonopah, at Butler, Nev., is in Salt Lake City, Utah.

W. DAHL of the Chicago & Spokane Placer M. Co. of Pierce, Idaho, is in Chicago, Ill.

M. S. TAFT of Walker, Ariz., superintendent Victor mine, has returned from New York.

W. W. EMMETT is superintendent of the Colorado & Telluride M. Co. at Central City, Colo.

T. R. JONES is manager of the custom department of the United States smelter at Bingham, Utah.

MANAGER P. L. FEARN of the White Knob M. Co. mines and smelter at Mackay, Idaho, is at Mackay.

W. L. REID is mill superintendent Smuggler-Union M. Co., Telluride, Colo., vice W. H. Davis, resigned.

J. H. MACKENZIE of Chicago, Ill., is at Gilt Edge, Mont., looking over the Gilt Edge mining property.

W. GARRICK succeeds A. L. Taylor as manager W. T. Garratt & Co., brass founders, San Francisco, Cal.

F. F. FULLMER, manager of the Beatrice mine, in the Lardeau, is in Spokane, Wash., from Camborne, B. C.

M. L. REQUA of Oakland, Cal., has been elected president of the Pacific Steel & Wire Co. of San Francisco, Cal.

W. E. HUMPHREYS, secretary Japan Mines Co., San Miguel, Colo., leaves Denver next week on a trip to Europe.

PRESIDENT SOPERS of the Bayard M. Co. at Golden, New Mexico, is visiting their mines from Toronto, Canada.

W. L. WATTS, E. M., of Los Angeles, Cal., is at Camella, Cal., making examinations in the new oil district there.

J. C. CAMPBELL, superintendent of the Murchie mine, near Nevada City, Cal., has returned from San Francisco, Cal.

FRANK PAUL, manager of the Groux copper mine at Pilot Knob, White Pine county, Nev., is in San Francisco, Cal.

S. CAMP, former superintendent of the Elkton Co., Cripple Creek, is superintendent of the Isabella properties in the same district.

L. WALKER has resigned as superintendent of the Cracker-Oregon mine, near Sumpter, Or., and is succeeded by D. M. Waters.

T. DENNIS of the Rhode Island succeeds P. R. Roberts as superintendent of the Ad venture mine and mill, near Houghton, Mich.

A. B. W. HODGES, superintendent of the Granby smelter at Grand Forks, B. C., has returned from a trip to southern California.

E. S. CAMPBELL has resigned as manager of the New Year's group at McCahe, Ariz., and is with the Knickerbocker Co. He has gone East.

MANAGER J. C. UNDERWOOD of the Yerkes M. & M. Co., near Altar, Sonora, Mexico, has returned to Camp Yerkes from Nogales, Ariz.

J. M. PARKER returned last week to Colorado Springs, Colo., from St. Joseph, Mo., where he has been on business for the Washington G. M. Co.

J. P. TURNER, formerly with the United States M. Co. at Bingham, is superintendent of the Yankee Con. M. Co., Eureka, Utah, vice P. M. McCree, resigned.

W. H. DAVIS has resigned as mill superintendent Smuggler-Union M. Co., at Telluride, Colo., to take the management of a cyanide plant for the Idaho G. M. Co. at Weiser, Idaho.

J. B. COOK of Los Angeles, Cal., recently returned from a six weeks' trip through the mines of San Bernardino county, where he made some examinations for himself and associates.

A. L. TAYLOR has resigned as manager W. T. Garratt & Co., brass founders, San Francisco, Cal., to devote his time to the Calaveras Development Co., with hydraulic mines near Railroad Flat, Cal., of which he is president.

IN the Union Iron Works of San Francisco, Cal., at the annual election on the

4th inst., the following officers were elected: Chairman of the board, H. T. Scott; president, W. G. Dodd; secretary and treasurer, C. N. Champion.

GEO. H. GIBSON has resigned his position with the Westinghouse Co.'s publishing department of Pittsburgh, Pa., to accept a position with the B. F. Sturtevant Co. of Jamaica Plain Station, Boston, Mass. Mr. Gibson was formerly a member of the editorial staff of the Engineering News of New York City, and is a graduate of the engineering school of the University of Michigan.

Commercial Paragraphs.

THE Eagle Engine Co. of San Francisco, Cal., has installed a complete shop, 317 319 Mission St., and are already running overtime to catch up on orders for their distillate engines. H. L. Marsh is in charge of the sales department. Catalogues will be furnished on request.

THE Jeanesville Iron Works Co.'s Denver branch reports the following sales recently: Compound pump for Mexico, 1600 feet lift through 7 miles of pipe; 16x10x12 standard pump to Salda smelter; 12x4x12 solid end to coal mine, 800 feet lift; electric station pump shipped to Mexico, 1000 feet lift. Jeanesville shops are very busy on large contracts.

THE J. Hendy Machine Works of San Francisco, Cal., have finished and delivered three sets, duplex, belt driven, 14x18-inch air compressors for the Edison Electric Co. of Los Angeles, Cal., to be used on their tunnel work at the Kern river. They have also finished installing a hoisting and compressor plant for the Fresno Copper Co. of two 80 H. P. boilers, a 75 H. P. double cylinder, double drum hoist, one single steam 14x18-inch compressor, drills and cages.

Books Received.

"Manual for Resident Engineers," by F. A. Molitor, C. E., and E. J. Beard, C. E. Under this title a neat little volume of 118 + IV pages has been published. The book contains general information on construction work on railroads, and incidentally gives much valuable data on excavating generally, and contains many pointers for the use of those in general charge of such work where constant personal supervision is impossible; \$1 cloth; John Wiley & Sons, New York.

Catalogues Received.

Catalogue No. 15 of the Union Gas Engine Co. of San Francisco, Cal., finely portrays seventeen years of progress and prosperity in the building of gas engines. In this treatise are twenty-eight full page views of Union gas engines of different styles and sizes. A copy of this edition will be sent to any address on application.

Obituary.

W. H. JAMES of Denver, Colo., died Jan. 29th of heart trouble, aged 65 years. He went to Colorado in 1860, was active in organizing the Grant Smelter Co. and the Colorado Fuel & Iron Co., and had large mining interests at different times. He was a native of Monmouthshire, England.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

OIL BURNER.—No. 719,345. Jan. 27, 1903. L. H. Lewars, Golden Gate, Cal., one-half assigned to D. E. Garrett and H. J. Perreau of West Berkeley, Cal. This invention consists of an essentially horizontal steam or air conducting pipe and oil conducting pipe with the discharge end approximately at right angles with the discharge end of the steam or air pipe. Within these two pipes are fixed nozzles having conical ends, which are brought together at right angles, so that the oil delivery from the depending or vertical pipe is caught by the steam discharge from the horizontal pipe and thoroughly atomized and blown into the spray within the furnace, where it is to be ignited. The nozzles are screw-threaded or otherwise so fitted into the pipes as to be adjustable to or from the angle at which their axes meet. The object of the invention is to provide a burner of such character that the steam or air and oil are brought together at

the instant of their delivery from their respective nozzles in such a manner that the oil is blown into a very fine spray at the point where it is to be ignited.

ORE CONCENTRATOR.—No. 719,181. Jan. 27, 1903. Clarence Brown, Bishop, Cal. This invention is designed to separate the valuable portion of comminuted ore from its gangue. It consists in an ore concentrator, the combination of an open center frame; spring standards supporting the same; a circular table of disked form, having a hollow shaft leading from its bottom; a series of radiating strips upon the table, curved continuously in one direction and made highest at their inner or lower ends adjacent to the shaft opening and tapering and substantially merging into the surface of the table at their outer ends, a ring inclosing said shaft and having oppositely located trunnions journaled upon said frame; means for tilting the ring and fixing it in a tilted position; and means for imparting to the table a step-by-step rotation.

FISH CLEANING APPARATUS.—No. 719,235. Jan. 27, 1903. J. Johnson, San Francisco, Cal., assigned to Alaska Packers' Association, a corporation, of San Francisco, Cal. This invention relates to an apparatus designed for the cleaning and dressing of fish, such as salmon preparatory to packing into cans for preservation and shipment. It consists in devices by which the fish is carried through an apparatus with suitable guides and separators, and saws so located and driven with relation to the passing fish as to cut off the fins, devices for splitting, disemboweling, and cleaning out the interior of the fish successively. It is especially designed to carry the fish through the apparatus with the belly downward and to so dispose the splitting cleaning mechanism and brushes with relation to the passing fish that the soft parts removed in the disemboweling process will be delivered downwardly and clear of all the mechanism, which is thus preserved from clogging, and use is made of the force of gravitation in disposing of waste material.

STRUCTURAL METAL SUPPORTS.—No. 719,191. Jan. 27, 1903. T. Collins, San Francisco, Cal. This invention relates to improvements in metal structures used in partitions and ceilings or wherever a support or frame of extreme lightness and thinness is desired with utmost rigidity is needed. It consists essentially of supports or studs angularly slotted, and angle-shaped transverse bars adapted to rest in these slots, the edge of the studs and the vertical faces of the cross bars being in the same plane (the vertical faces of the cross bars may have burrs on them by which metal rubbing may be attached, said studs and bars being rigidly retained in position in relation to each other without the use of rivets, bolts, or clenching devices.)

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR THE WEEK ENDING JANUARY 27, 1903.

719,181.—CONCENTRATOR.—C. Brown, Bishop, Cal.
719,191.—STRUCTURAL METAL SUPPORT.—T. Collins, S. F.
719,235.—CAN SALTING MACHINE.—W. E. Dement, Blaine, Wash.
719,337.—GEAR.—R. B. Hain, Los Angeles, Cal.
719,345.—GOVERNOR.—R. B. Hain, Los Angeles, Cal.
719,230.—TEMPERATURE RETAINER.—J. Hommel, Los Angeles, Cal.
719,236.—FISH CLEANING APPARATUS.—J. Johnson, S. F.
719,345.—OIL BURNER.—L. H. Lewars, Berkeley, Cal.
719,356.—WATER HEATER.—J. McCartney, S. F.
719,345.—FUSIBLE PLUG.—H. D. Morton, S. F.
719,038.—FLOORS, ETC., CONSTRUCTION.—J. C. Pelton, S. F.
719,373.—GAS GENERATOR.—W. A. Robertson, Alameda, Cal.
719,051.—PLANE.—W. L. Scott, S. F.
719,381.—COMPASS.—H. E. Seymour, S. F.
719,391.—GAS GENERATOR.—E. B. Stoner, Astoria, Or.
719,273.—TREATING ORES.—Z. B. Stuart, Los Angeles, Cal.
719,274.—TREATING ORES.—Z. B. Stuart, Los Angeles, Cal.
719,275.—SPINNING TOY.—J. S. Thornburg, Los Angeles, Cal.
719,089.—SAW HANDLE.—J. A. Williams, Dallas, Or.
719,393.—WELL DRILL.—M. Ziegenfuss, Burns, Or.

Latest Market Reports.

SAN FRANCISCO, Feb. 6, 1903.

METALS.

SILVER.—Per oz., Troy; London, 21½ (standard ounce, 925 fine); New York, bar silver, 47½c, refined (1000 fine); San Francisco, 47½c; Mexican dollars, 38 @ 39c San Francisco, 37½c New York.

COPPER.—New York: Standard, \$11.50; Lake, 1 to 3 casks, \$12.75; carload lots, \$12.00; Electrolytic, 1 to 3 casks, \$12.37; carload lots, \$12.25; Casting, 1 to 3 casks, \$12.25; carload lots, \$11.50. San Francisco: \$14.00. Mill copper plates, \$17.00; bars, 18@24c. London: £56 spot per ton.

Copper is advancing fraction at a time, each week noting an increased price. That it will reach and pass 13 cents, there now seems little doubt, and this increasing price cannot fail to prove a stimulus to the industry generally. There are many mines that cannot be operated profitably on 11 or 12 cent copper, which will pay handsomely at 13 cents and over. The Boston Financial News says: "Those in close touch with the largest selling agency in the country report that bullish sentiments are expressed in that quarter where it is said that the policy pursued a

little over a year ago in reducing copper prices from 17 cents to below 12 cents was based upon a misconception of existing conditions, and that, had prices been held at the 17 cents level but for three months longer than they were, the surplus accumulated during 1900 would have been absorbed by the consuming buyers of 1902, but at the lower levels of 1902. It should be satisfactory to both producer and consumer to know that the accumulations of past years and mistaken policies have no longer an existence."

LEAD.—New York, \$4.12½; Salt Lake City, \$3.50; St. Louis, \$4.00; San Francisco \$4.50, carload lots; 4½c 1000 to 4000 lbs.; pipe 5½, sheet 6, bar 5½; pig, \$4.75. London: £11 7s 6d per long ton = 2.47c per lb.

SPELTER.—New York, \$4.95; St. Louis, \$4.50; London, £20 7s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9½c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 10c; 300 to 600 lbs., 11c; 100-lb. lots, 13@15c.

TIN.—New York, pig, \$28 65@28 75; San Francisco, ton lots, 31c; 500 lbs., 31c; 200 lbs., 31½c; less, 32c; bar tin, 3½, 35c @ 37½c. London, £132 10s spot.

PLATINUM.—San Francisco, crude, \$18.00 per oz.; New York, ingot, \$19 00 per Troy oz. Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, \$45.50@46.50; large lots; London, £8 15s; San Francisco, local, \$45 50 per flask of 76½ lbs.; Denver, \$49.50. Export, \$43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 35c; Eclipse, 37½c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 20c; San Francisco, Plumbers', 100-lb. lots, 16.65c.

NICKEL.—New York, 50@60c per lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$22.10; gray forge, \$20.50; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$23.00; open hearth billets, \$30.00; San Francisco, bar, 7c to 12c per lb.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 25@26c per lb.; carloads, 24@24½c; in tins, 35c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 2½@3c per lb.; caustic soda, in drums, 3@4c per lb.; Cal. s. soda, bbls., \$1 25@1 50 per 100 lbs.; sks., \$1.05; chloride of potash, 12@13c; nitrate of potash, bbls., 8c; caustic potash, 10c in 40-lb tins; borax concentrated, 7@8c per lb.; roll sulphur, 4@6c; ground sulphur, 4@6c; flour sulphur, French, 2@3c; alum, \$2.00@2.25; California refined, 2 @ 2½c; sulphide of iron, 9c per lb.; copper sulphate, 5@7c; chloride of lime, spot, \$3 00@4 00; sulphuric acid, in carboys, 68% B, 2c per lb.; nitric acid, in carboys, 8c per lb.

LUMBER.—(Retail): Pine, ordinary sizes, \$20.00@22.00; extra sizes higher; redwood, \$22.00@23.00; lath, 4 feet, \$4.25 @ 4.50; pickets, \$19.50; shingles, \$2.35 for No. 1 and \$2.00 for No. 2; shakes, \$13.50 for split and \$14.50 for sawed; rustic, \$26.00 @ 32.00.

NAILS.—Per keg (list prices): No. 20d to 60d, Wire, \$3.35; Cut, \$3.35; 10d to 16d, Wire, \$3.35; Cut, \$3.35; 8d, Wire, \$3.40; Cut, \$3.40; 6d and 7d, Wire, \$3.50; Cut, \$3.50; 4d and 5d, Wire, \$3.60; Cut, \$3.60; 3d, Wire, \$3.75; Cut, \$3.75; 2d, Wire, \$4.00; Cut, \$4.00. Special rates for carload lots.

GENERAL SUPPLIES.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 60%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9c; less than one ton, 11c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2 per keg.

CAPS.—3x, \$5.50 per 1000; 4x, \$6.50; 5x, \$8; Lion, \$9, in lots not less than 1000.

FUSE.—Triple tape, \$3.60 per 1000 feet; double tape, \$3.00; single tape, \$2.65; Hemp, \$2.10; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10½c per set; 14 oz., 40s., 9½c.

CEMENT.—Germania, \$2 50 @ 2 75; Hewmoor, \$2 90; Trowell, \$2.90; Portland, \$2 50@2.75 per bbl.

LIME.—Santa Cruz, \$2.25; Roche Harbor, \$2.25 per bbl.

OILS.—Linseed, boiled, bbl., 56c; cs., 61c; raw, bbl., 54c; cs., 59c; lots of 5 bbls., 1c less; Lucol oil, boiled, bbl., 50c; cs., 55c; raw, bbl., 48c; cs., 53c. Kerosene—Pearl, per gal., 22½c; Astral, 22½c; Star, 22½c; Extra Star, 25½c; Eocene, 24½c; Elaine, 27½c; Water White, in bulk, 16c; Mineral Seal, iron bbls., 18½c; wooden bbls., 21c; cs., 24c; Mineral Sperm, cs., 28½c; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 21c; do., cs., 27½c; 63° Naphtha or Benzine, deodorized, in bulk, per gal., 16c; do., in cs., 22½c; Lard Oil, No. 1 bbl., \$1.00; cs., \$1.05; Neatsfoot Oil, bbl., 70c; cs., 75c; No. 1 bbl., 55@57½c; cs., 57½@60c; Sperm, crude, 50@60c; Natural White, 55c; Bleached do, 70c; Whale Oil, cs., 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6c; 1 ton and less than 5 tons, per lb., 6½c; 500 lbs. and less than 1 ton, per lb., 6c; less than 500 lbs., per lb., 6½c; in 25-lb. tin pails, 4c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, 4c per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6c; do. in kegs, 6½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$3.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lots, Eastern and foreign: Wallsend, \$6.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8; Cumberland, \$12; Cannel, \$9.00; Welsh Anthracite, \$11.50; Rock Springs, \$9.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13 in sacks; Sunnyside, \$8.50, long ton.

RED LEAD.—One ton and over at one purchase, per lb., 6c; 500 lbs. and less than 1 ton, per lb., 6½c; less than 500 lbs., 7c.

LITHARGE.—Pure, in 25-lb. bags, 8 @ 9c per lb.

BONE ASH.—Extra No. 1, 5@6c per lb. No. 1, 4@5c.

BORAX.—Concentrated, 7@9c per lb.; powdered, 9@12c; fused, 25@30c.

BISMUTH.—Subnitrate, per lb., \$1.60.

BONE ASH.—4c per lb.

BORAX.—Crystal, 7c; calcined, 25c.

COPPER.—Sulphate, 5@7c.

MANGANESE.—(90% and over) per lb., \$1.25.

MOLYBDENUM.—25c. per gramme; 1000 grammes—2½ lbs.

CHROMIUM.—(90% and over) per lb., \$1.25.

SODIUM.—Metal, per lb., \$1.25.

MERCURY.—Bichloride, per lb., 90c.

PHOSPHORUS.—(American) per lb., \$1.00.

SILVER.—Chloride, per oz., 90c@1.00; nitrate, 55c.

URANIUM.—Oxide, per lb., \$3.50.

ZINC.—Metallic, chemically pure, per lb., 50c; dust, per lb., 10c; sulphate, per lb., 04c.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

THE CALIFORNIA DEBRIS COMMISSION having received applications to mine by hydraulic process from Andrew Custidge in Forty Nine Placer Mine, near Mountain Ranch, Calaveras County, Cal., draining into McKinley Creek which reaches Calaveras River from Frank Vere in Elm Placer Mine, near Quincy, Plumas County, Cal., draining into Taylor Creek which reaches Feather River; from Nelson Contracting Co. in Calaveritas Hill Mine, near Calaveritas Hill, Calaveras County, Cal., draining into Oneil Creek which reaches Calaveras River, gives notice that a meeting will be held at Room 56, Flood Building, San Francisco, Cal., Feb. 9, 1903, at 1:30 P. M.

WANTED POSITION AS MILL SUPERINTENDENT or foreman of an amalgamation and concentration mill; have had 18 years' experience; am a good machinist and understand handling all kinds of machinery; can furnish best of references; at the present time hold the position of superintendent for one of the largest companies in the State of Colorado, but wish to change and will go to any country. Address H. D., care of Mining and Scientific Press.

WISH A POSITION AS ASSAYER, OR STEAM Engineer, or Tool Sharpener, or will act as Superintendent of mines. Jesse L. Wetmore, Hotel Merritt, Oakland, Cal.

Variations in Hoisting Machinery.

There is no kind of mining machinery having so many variations of type as hoisting engines, not only as to size and capacity, but as to detail of construction. This great variation in machines built to perform essentially the same kind of work represents the differing ideas of the numerous different manufacturers, and also, to some extent, the ideas of their patrons. Some favor geared hoists, believing them to be the only safe and reliable machine for the purpose. Others want the friction hoist, as the geared hoist is "too noisy." A third class want direct-acting machines, and hoists of this type are usually preferred in large installations, where the workings extend to great depth. There is much difference in the several arrangements of all hoisting engines, and mine managers have positive but differing ideas as to brakes and the method of their application.

Some require hoists which may be operated by either steam or air; still others have their hoists built for steam and water power, being made quickly interchangeable.

The latest type of hoisting machinery introduced is the electric, and in these is also found a great variety of design. This is largely due in this latter class of hoisting machine to the greatly varying conditions at mines, and even at the same mine the load particularly is greatly variable, and manufacturers of electric machinery for mines have given much attention to the construction of a hoisting machine that will satisfactorily meet the varied requirements. On this page are three engravings from the catalogue of the General Electric Co. of Schenectady, New York, of large electric hoists, located in widely separated parts of the country. One is that at Le Roi mine, Rossland, B. C., a large double reel machine operated with induction motor, built by the Denver, Colo., Engineering Works. Another is that of a Lidgerwood double reel hoist, also run with induction motor, at the Cochiti mine, Albemarle, N. M. The third represents the electric hoist at the Union mine, on the Comstock lode, Virginia City, Nev. This hoist, built by the Risdon Iron Works of San Francisco, Cal., is of peculiar construction, being made to operate a continuous rope. The rope is wrapped four times around an idler, to secure necessary friction for lifting. From the main driving reel the rope is carried over a head sheave and down one compartment of the shaft, under a tail sheave and up the adjoining compartment of the shaft, where it passes over a second head sheave and onto the driving drum. One cage is secured between the

Double Drum Hoist With Induction Motor, at Le Roi Mine, B. C., Built by Denver Eng. Works, Denver, Colo.

ends of the rope, and the other cage is fastened by means of heavy iron clamps, one above and the other below the cage, in the opposite compartment of the shaft.

THE work of the United States hydrographic division of the Geological Survey is continued under direction of F. H. Newell. The report for 1901, recently issued, contains valuable data and the result of the work already done in various parts of the country. The work of this branch of the Survey consists in measuring the volume of water in streams and estimating the flow both over and under ground. In this not only the quantity but the quality of the water is determined, and particular attention is given to water conservation. Mr. Newell says: "Water can not be considered a resource unless it can be made available when wanted, and, therefore, the determination of the practicability of holding the waters in time of flood until time of drought underlies

any statement of water supply." The work on water supply has been in progress since 1888 and much valuable work has been done by the Survey.

THE public spirited men of British Columbia have recently organized for the promotion and fostering of the mining industry in that province under the name of the Provincial Mining Association. Mine owners, superintendents and working miners are eligible to membership, as also are merchants, farmers and all others who are directly or indirectly interested in the development of the mineral resources of that section. The specific purpose is to bring about an improvement in conditions; to influence legislation in the interest of the mining industry, and to generally place mining on a more secure and satisfactory footing. Organizations of this character can accomplish much good work in behalf of the mining industry, and that in British Columbia will no doubt make its influence felt.

THE best thing the California Legislature can do with the "flashing" of fuel oil is to let the whole subject alone. The matter may not be beyond its comprehension, but it is apparently beyond its jurisdiction. It is in order for the California legislators to make adequate appropriation for suitable display of California's mineral wealth at the coming St. Louis Exposition, and to see that whoever are sent to represent the State and disburse the money shall have some knowledge of the requirements of the situation.

IN estimating the value of a gold mine, where it is evident several years, possibly a score of them, will be required to exhaust the available resources, there is one factor which may be entirely eliminated—that of the value of the product. Gold does not fluctuate in value, being itself the standard of values. The cost of working the mine may increase or decrease with the coming years, as conditions change, but the price of gold remains stationary through these numerous changes of condition and value in other things.

A PARTIAL solution of the labor problem in the mines of the Transvaal seems to have been found by the labor agents of the companies who are in Europe. It is stated that 6000 Italians have been enlisted at a wage rate but little above that demanded by Chinese. It is also reported that large numbers of workers will be secured in South Russia. Cheap European labor has been introduced into the mines of the United States, but experience has shown that these men, willing at first to labor for a mere pittance, as soon as they become proficient in their work demand about as much for their services as Americans or other experienced miners.

A Valuable Mine Report.

The ninth annual (1902) report of the Portland Gold Mining Co. of Cripple Creek, Colo., recently issued, is one of the most complete that has ever been published by any mining company of that State. It contains numerous illustrations and maps, with sectional drawings of the geology and mine workings. These latter not only give general information, but in many cases give details of the geological occurrences of particular portions of the veins, such as are not often found outside of papers published by technical societies.

The report goes into the problems of mining encountered and gives some valuable information applicable particularly to the Cripple Creek district. Here the problem of getting the best results from veins of the character found in the district is one of hand concentrating. Owing to the physical condition of the ore, mechanical concentration is unsatisfactory. The important question has been where the hand sorting should be done—under ground or on the surface—and it has been found advisable in some cases to perform the first stage of this operation in the stopes, and the second on the surface. Under the conditions existing in the district it has been found that the cost of getting the material out of the chutes, teaming, hoisting, sorting in the ore houses and teaming to the waste dumps, is greater than stoping of ore and timbering. Here the "fines" constitute the most valuable portion of the ore, and this renders underground sorting as now practiced, and filling with the waste, inadvisable, and in some cases prohibitory, owing to the loss in the fines, which are the richest portion of the ore. Where filling is imperative, owing to great size of stopes, mining has been accomplished by spreading canvas on the floor of the stope, covering it with a plank floor, over which the heavy lagging is laid to protect the floor and canvas from blasting. In this manner, although involving extraordinary expense, a large percentage of the high-grade fines is recovered and the stopes are filled with waste. This latter plan has not been in operation long enough to demonstrate its relative economy. The fact that this method is more expensive is against its adoption, but a choice between this method and that of hoisting all the ore and sorting at the surface will be made. By the latter cheaper method a larger volume of material results, but it is much lower in grade than that obtained by the former plan of underground sorting. When transportation and treatment charges on the resulting larger volume of ore is taken into consideration, it may be found that there is little difference in cost per ounce of gold produced. Still it is not desirable to leave valuable material in the mine which could as well come out.

It is not improbable that some variations of the underground method of sorting will be the outcome of this necessity by which the expense may be materially reduced, while recovering practically all the ore of value.

Possibly the introduction of grizzlies constructed of movable timbers on the floors of the stopes may prove an advantage in dealing with this proposition. These may be moved at will and replaced on a higher floor. By this method the large rocks are prevented from falling into the ore pockets below and clogging the chutes. The fines produced by blasting pass through, and all of the subsequent spalling and sorting by hand may be accomplished on these grated floors, the valuable material passing below to the chutes, from which it may be removed, the coarse waste to then be sent out in the same manner, after the ore has been drawn off, or it may be stowed in the stopes.

Grizzlies of this description are in use in the Gwin mine, Calaveras county, Cal., and are employed to facilitate breaking coarse ore before permitting it to descend into the chutes. In the narrow stopes of the Portland mine all the ore broken is raised to the surface. In some of these veins the ore is mined "on the run." That is, the ore is broken from wall to wall, and as the stope progresses upward the ore is drawn only in such amount as will keep the floor within convenient distance of the hack. When the stope has all been broken down the ore remaining is all drawn out and the walls allowed to cave.

The economy of self dumping skips over cages has

been recognized and these have been introduced to lessen the cost of hoisting. They are run in balance. By the use of skips the hoisting capacity of the shaft is increased and topmen are reduced in number.

The report shows that during the first six months of the year 162 857 tons of ore were mined at a cost for mining of \$3 26 per ton, and during the second half of the year 148 997 tons were mined at an expense for mining of \$2 97 per ton. During the year 15,173½ feet of development was done at a cost of \$161,300.60, of which \$33,703.73 was charged to stoping, making the cost of dead work \$122 596 87. The total cost of operating amounted to \$1,067,738 93, the cost per ton being \$9 508. The mine produced 116,701.19 ounces of gold, valued at \$2,334,023 76. The actual expenditures, however, on all accounts were \$1,875,296 96 and the net profit over all expenses was \$471,819 76. The various departments of expense are segregated as follows: Breaking ore includes the cost of breaking ore in stopes and delivering it to trammers; this includes the labor of miners, machine men and shovelers, cost of explosives, running machines, etc. Trimming comprises the cost of taking ore from the chutes and delivering it at the shaft, including the labor of trammers, cost of tracks, repairs on cars, etc. Timbering comprises the cost of timbering the stopes in labor and supplies. Hoisting comprehends the cost of raising ore to the surface, including the cost of steam, labor and repairs in operating the hoists, repairs to shafts and labor of cagers and topmen in putting cars on cages and taking them off. Sorting and loading includes the cost of concentrating ore by hand labor in the ore houses, loading it on cars and shipping it; also, cost of repairs in ore houses. Pumping is the cost of draining the mine.

Development charged to stoping: This is the cost of all exploring work that produced any ore. In the second half of the year the proportion of ore produced was greater than the first half, making a difference in the cost per ton.

These are the principal charges. Others are chiefly on account of office and other extraneous expense, interest on equipment, insurance, etc. The total cost per ton was about \$9.25, or about \$8.10 per ounce of gold produced.

The Expense of Deep Mining.

As the workings of a mine extend to greater depths, the cost of operation is naturally supposed to increase. The main factors in increasing the expense are greater power required for hoisting, drainage of mine workings and ventilation, with a greater consequent outlay in machinery, which means increased interest charge on account of equipment. There are other factors which are given consideration when mining to great depths is in contemplation, these being the encountering of large volumes of water and increase in temperature to an abnormal degree. These are merely problematical, as the deep workings may not prove to be materially hotter or wetter than those nearer the surface, and in practice it frequently occurs that there is no considerable increase in heat, and the amount of water found is actually far less than is encountered in the upper levels. As a matter of fact, many mines working at great depth actually mine and treat their ore at a lower cost per ton than had been done in the upper workings, this being made possible by the thoroughly systematic development of the mine and improved methods in operating. The heavier and costlier machinery has a far greater efficiency, and much larger quantities of ore and materials can be handled at proportionally less expense. In many mining regions the mines operating below 2500 feet are doing so at a less cost per ton than that obtaining at higher levels in the earlier history of the mine. Where new enterprises are obliged to sink deep vertical shafts to reach their veins, as is the case at some of the copper mines of the Lake Superior region, on the Rand, in South Africa, and elsewhere, several years are required for preliminary work and the consequent expenditure of a large amount of money without return, but the managers of such enterprises should be able to get an approximate idea of the expense from the operations of companies already working at the depth which it is proposed to reach and prepare to discount it.

CONCENTRATES.

"MAN ENGINES" are not in use in American mines. They originated in Cornish tin mines.

THE cyanide process has been successfully applied in the extraction of gold from auriferous arsenical sulphide ores.

CASSITERITE (tin oxide) is usually associated with granite or rocks of granitic type. It contains when pure 78.76% tin and 21.24% oxygen.

WHERE two veins unite on their dip to form one vein the prior locator is entitled to take all that lies below, including the place of intersection.

THE lightest of metals is lithium, specific gravity, 0.59. It is the only known element with which nitrogen will directly combine at ordinary temperature.

SIDERITE (carbonate of iron) occurs in the Payne mine at Sandon, B. C., which is naturally magnetic, a very unusual property in this mineral before roasting.

ARSENIC occurs abundantly in the free state in some localities, but is usually combined with some other element, particularly iron and sulphur. Cobalt and arsenic are frequently associated.

QUARTZ PORPHYRY is often associated with or contains bodies of copper ore, but so do other rocks as well. Limestone is not an accompaniment of all large copper mines, though prominent in Arizona.

THE pulverized mineral from Santa Ana, Cal., is apparently fine volcanic ash, either naturally or artificially pulverized. Except, possibly, as a polishing material for rough work, it has no commercial value.

THE slope angle of most hillsides is less than 30°, and very few exceed 35° unless they be abrupt precipices. The normal slope angle of a dump is about 35° and varies little from this no matter what the material.

THE silver found in some of the copper mines of the Lake Superior region is native metal and is not alloyed with the copper, nor does the copper contain a trace of silver. Often the silver is associated with calc spar.

HYDRAULIC MINING is of common practice elsewhere than in California. In Augusta county, Georgia, at the Crinora mine, which yields only manganese ore, it is sluiced out as in hydraulic treatment of gold gravel.

PROOF that \$500 worth of work has been performed on a mining claim must be supplied by the applicant for patent. Such proofs should be specific, and establish all the facts which are required by the deputy mineral surveyor.

ANY inhabitant of Mexico may prospect for mineral on the public lands by first giving notice in duplicate to the local government mining agent. The notice must state accurately the boundaries of the territory to be prospected.

THE appearance of copper carbonate incrusting surface rocks is not always a safe indication that a valuable ore deposit lies below. Nor is an iron gossan, even in a region producing copper, an infallible index of copper value in depth.

EXPERIMENTS to redetermine the density of the earth are to be made in the Tamarack shaft, near Houghton, Mich., by F. M. McNair of the Michigan College of Mines and J. E. Hayford of the United States Coast and Geodetic Survey.

THE laws of California do not require hoisting engineers to have a certificate, but the engineer who cannot remember the hell signals long enough to comply with directions from below is a dangerous man and should be employed elsewhere.

CHERT in limestone sometimes contains gold in paying quantity, though it is unusual. In the Pocahontas mine in Squaw Creek canyon, about 12 miles west of Deadwood, South Dakota, rock of this description was found containing about \$3000 per ton in free gold.

In refining copper from a sulphate solution, one kilowatt hour at a potential difference of 0.5 volt will produce 2.36 kilos of copper. From a chloride solution working at the same potential difference (0.5 volt) 4.72 kilos of copper are produced by one kilowatt hour.

SILVER CYANIDE is very similar in its properties to chloride, iodide and bromide of silver. It is obtainable by adding a solution of hydrocyanic acid to silver nitrate. It is soluble in a solution of potassium cyanide, from which crystals of silver cyanide may be obtained by evaporation.

THE government of Uruguay, South America, gets a percentage of all gold produced. In mining, French

machinery and appliances are exclusively used. There are no mines of copper, gold or silver in Paraguay, South America. Copper is found, but has never been developed.

WHERE prompt filling with waste of mine workings is practiced, timbers of moderate dimensions may be employed. Where this has been done experience has shown that timbers of large size are unnecessary, though they will support the ground a longer time without filling than smaller timbers.

THE base of the ore from Azusa, Los Angeles county, Cal., is baryta (heavy spar). The pink mineral is erythrite, a hydrous cobalt arsenate (also called cobalt and peach bloom). The black, soft mineral is silver sulphide. A small quantity of native silver may also be seen in the specimen.

MINING PROPERTY in Mexico legally acquired is irrevocable and perpetual as long as the Federal tax upon the property is paid. Water raised to the surface from the mine workings is the property of the mine owner, but he becomes responsible for any damage done by the water flowing over the property of others.

THE electrolytic method is coming to be the general way of copper determination. It were well if some standard method could be agreed upon for gold and silver assaying. Different methods give different results, and disputes can usually be obviated by mutual agreement in individual contracts as to what method of assay shall be adopted.

MICA of good quality and in sheets larger than 4 inches square meets with ready sale. Nearly every large electrical company is in the market. The Idaho specimen is muscovite; the Shasta county, Cal., sample is of inferior grade. A. Seboonmacher or E. Munsell, New York City, are dealers in mica. In 1901 mica was imported into this country to the value of \$335,054.

In a copper sulphate solution of about 50 c.c., containing not less than 0.0128 gram of CuO, the copper may be completely precipitated as oxalate by adding oxalic acid. The copper is precipitated all the more easily in the presence of a moderate quantity of nitric acid, about 5 c.c. of the concentrated acid. Under these conditions, cadmium, arsenic, iron, small quantities of tin, but not zinc, remain in solution.

THE dark-colored zinc blende usually contains iron and manganese. When pure this mineral is nearly colorless and transparent. One locality in New Jersey produces specimens that are white. Most commonly it is light brown to yellowish. When associated with galena it often has a sub-metallic luster and is sometimes mistaken for the former. When treated with sulphuric acid sulphuretted hydrogen is evolved.

FULLER'S EARTH may be tested by its physical properties to a certain extent, but an analysis is most satisfactory. It is usually light gray, yellowish or greenish yellow to light brown in color, has a somewhat greasy feel, is earthy and soft with a greasy streak; it does not adhere to the tongue. Placed in water, it absorbs a large volume of the water, cracks and falls into powder, but is not plastic, and cannot be moulded.

By "yellow copper ore" is meant the common copper-iron sulphide (chalcocopyrite). It contains sulphur 35%, copper 34.5% and iron 30.5%. To meet this formula, the mineral must be pure. The copper content frequently falls below the percentage stated owing to a mechanical admixture of iron pyrite which may or may not be visible to the eye. For this reason a mineral supposed to be pure chalcocopyrite often contains less than 20% copper.

A GOOD WAY to guard against a mining or milling failure is to get competent ore examination by one who can correctly determine its necessary treatment. With sufficient ore to justify the expense, the plant requisite should be bought from men able to furnish a good quality of machinery throughout. All this will cost considerable more at the start than not to do it, but if the intent be to work the mine, the plan suggested will prove of ultimate economy.

WHENEVER a dispute arises as to the right of a claim owner to follow a vein on its dip beyond the side lines of a claim the defendant must establish the apex of his vein on the surface, and prove its continuity and identity from the apex to the point of dispute. It is not necessary that the apex of the vein extend through both end lines of the claim, or through either of them, so long as sufficient of the vein is exposed in the apex to give the privilege of extralateral right.

"CHICKEN LADDERS" is a colloquial term applied to the notched poles used in many mines, and particularly in Spanish-speaking countries, as a means of ascent and descent in the workings. The native miners of Mexico and some of the Central and South American States climb these notched poles through hundreds of feet of mine workings, carrying heavy burdens of ore in leather sacks on their backs. In some countries notches are cut in the rock of the footwall for a similar purpose.

It is a mistake to consider as proved any comparison

of costs by some other mine similarly situated. Every mine is a separate and distinct problem of itself. Seldom can the same costs be figured in precisely the same work in two different mining properties. There is always just enough difference in some one item—the extraction of ore, or the water, or the stamps, or the plates, or something—to upset any calculation that because the costs in one mine were so and so they will be the same in another precisely similar property.

OIL for a gas engine may well be of two kinds—a heavy, viscous, mineral oil of high fire test for the cylinder, and a good quality of engine oil for the bearings. The best oil is none too good; with too little oil there is greater wear on the working parts, greater consumption of water, more frequent needed cleaning of packing rings and greater fuel consumption, because of greater friction. With too much oil there is a general stickiness, and often a clogged mixing valve. The best oil in moderate quantity insures the best results.

GABBRO is a basic rock, wholly crystalline, with granitic structure. It is composed chiefly of diorite (a peculiar, lamellated or foliated pyroxene), and plagioclase with magnetite, titanite, apatite and olivine. It occurs in masses, dikes and sheets. There are several varieties named according to the presence of certain minerals not essential constituents, as hypersthene-gabbro, hornblende-gabbro, mica-gabbro, orthoclase-gabbro, olivine-gabbro, etc. It is abundant in some regions where basic rocks predominate. In California it is often associated with serpentine.

THE separation of zinc from the complex sulphide ores of zinc, iron, lead and copper, which have always defied every attempt, seems now to have been satisfactorily accomplished by various forms of electro-magnetic separators. There are hundreds of thousands of tons of ore of this character lying on mine dumps, where it has been deposited because it could not be handled to profit. In Colorado they may frequently be seen, and at the Broken Hill mines of New South Wales ore of this character has been accumulating from the extensive operations there for years.

THE fact that an ore body extends underground beyond the end lines of a claim, though not so appearing on the surface, does not permit the owner of the exposed outcrop to go beyond his end lines. Most ore shoots have a trend along the strike of the vein, the direction of which it is sometimes difficult to determine until a large amount of development has been done. The direction of trend as indicated at and near the surface is not always constant below. A distinction must be made between dip of the vein and trend of the ore shoot, along the course of the vein.

WORK done outside of a claim or group of claims, if done for the purpose and as a means of prospecting or developing the claim, as in the case of tunnels, drifts, etc., is available as assessment work, the same as if done on the claim itself. Where there are more than one claim in the group, \$100 worth of work must be performed for each claim of the group. In the same manner, where the work is all done on a single location for the benefit of all the claims in the group, this work may be applied as assessment work on all, \$100 being expended for each claim of the group.

THE American Institute of Mining Engineers had on Nov. 1, 1902—the date of the last official report—a total membership of 3262—honorary members, 11; members, 3094; associates, 157. The rules of the Institute establish the following as the essential qualifications for eligibility to membership: "Members and honorary members shall be professional mining engineers, geologists, metallurgists or chemists, or persons actually engaged in mining, metallurgy or metallurgical engineering. Associates shall include all persons desirous of being connected with the Institute, and duly elected."

MISPICKEL, the sulpharsenide of iron, is not uncommon in quartz veins. It is somewhat softer than pyrite, is tin white to steel gray, often tarnished. It pulverizes to a dark grayish powder, and is often auriferous. It is decomposed by nitric acid and when auriferous the gold may be recovered in this way. Though sometimes very rich in gold, it is often barren of that metal. It is an ore often difficult to handle and large sums have been spent in futile attempts to amalgamate a high percentage of the gold present. When the mineral also contains cobalt (replacing part of the iron) it is known as danaite.

THE Kearns senatorial amendment proposes that the United States mining law shall be changed so that mining locations shall be rectangular in form, not to exceed 1500x1500 feet, and shall convey "the right of possession and enjoyment of all surface included in the lines of the location, and of all veins, lodes, ledges and mineral deposits throughout their entire depth, which lie within such surface lines extended downward vertically." That is, there would be no following of the vein on the dip, no "extralateral rights." The bill was published in full and editorially discussed by this journal last summer. It comes up for discussion in this session of Congress. From our standpoint it should become a law, as it would help the prospector and miner and discourage the expensive litigation that has been the bane of every mining camp in the country.

Stamp Milling and Amalgamation of Free Gold Ores.

NUMBER V.

Written for the MINING AND SCIENTIFIC PRESS by DANA HARMON, San Francisco, Cal.

It has also been said that fragile sulphurets are badly abraided by the wide plate flow and that therefore the sluice should be used. In other words, the wide plate increases sliming and the 20-inch sluice avoids it.

Put your hand into any narrow sluice and you will find the sand and sulphurets trailing along on the bottom. Fragile sulphurets are not any worse off upon a wide plate than in a narrow sluice.

But they are not so fragile; they stand quite a bit of cuffing. By way of illustration on this point, examine the mill records of Black Hawk canyon, in Gilpin county, Colo. Here are sulphurets pulverized minutely through 50-mesh screens, in deep mortars. I am not defending this Gilpin county method of milling. But it did well serve its special purpose and solved a baffling problem in the early '70s. The mill saving, including the values in the concentrates, was 93.8% of the gold and 71% of the silver on ores worth approximately \$42 per ton. By amalgamation alone the saving was 70.4% of the gold and 39.7% of the silver. This was on a lot said to be typical of the camp. I am quoting from T. A. Rickard's admirable book, "Stamp Milling of Gold Ores." To facilitate further comparison, let me quote his following figures on these Gilpin county ores:

Weight of stamp, 550 pounds.
Height of drop, 16 to 18 inches.
Discharge, 13 to 15 inches.
Drops per minute, 26 to 30.
Screens, No. 1½ hurr slot (50-mesh).
Crushing per stamp, one ton in twenty-four hours.
Concentrates, 12% to 20%.
Tables, 4 feet wide by 12 feet long on 2½-inch per foot grade."

I am inclined to think that if some one will discover another Black Hawk canyon, the Gilpin county stamp mill will not be the method used to recover the gold. But the mill did prove that sulphurets can be concentrated after being so finely ground that 70% of the pulp would pass a 100-mesh screen, and all of it through 50 mesh. One need not worry over fancied plate abrasion. We have had the same proofs at other districts.

DON'T ADD WATER OUTSIDE THE MORTAR—I think one needs just the same amount of water inside the mortar as out, and there is no better guide as to how much water to use in the mortar than to use just enough as will move the pulp properly over the plates. No reliance can be placed upon stated formulae of so many gallons per ton of ore.

The quantity of water is vital, and, so far as my observation has gone, nine millmen in ten use too much. Not one of these nine will agree with me in this—which only shows how obstinate men can be.

One reason for the excessive use of water, so common, is that the table has too little grade.

The millwright turns over a table 1½-inch to 1½-inch grade to the foot. It should be 2½-inch to 3 inches.

Don't be afraid of steep grades, for it means less water and clean table; no danger of scour.

DISTRIBUTING BOXES.—These are an abomination. The holes get plugged up; they incite the millman to careless use of quicksilver when rubbing up; they are traps to gather quicksilver, and let it out in lumps on the plates; they don't distribute pulp as evenly as the splash boards. (Fig. 2)

Globules of free quicksilver on the plates should never be tolerated. If there is a distributing box, the millman can lay the blame to the box. Take away the box and roh him of his excuse.

DON'T TURN ALL THE PULP ON HALF THE PLATE AREA WHEN BRUSHING UP.—We have seen the 4-foot plate with partition strip in center and distributing launder at the head. The battery is not hung up when brushing the plates, but all the pulp is turned to one side of the strip, while the men are working on the opposite side.

There can be no logical defense for this custom. If 4 feet width is needed at any moment, it is for all the moments. To confine all the flow to 2 feet width must inevitably scour. The only excuse urged is that it does not pay to hang up. I hardly think it pays any better to scour—the richer the ore the greater the loss. Build another battery if the mine will stand it. The average mine will survive the shock of a little hanging up.

The champions of the never-hang-up theory seldom, if ever, sample tailings when brushing up. They don't know their own losses. It is a well-known fact that upon ore of only \$8 value the plate just before brushing up will be plentifully sprinkled with coarse bits of amalgam. I suggest, by way of proof, that three tailings samples be taken from the 4-foot plate width within the ten minutes preceding the rubbing up, and then three samples from the 2-foot plate width during the ten minutes of rubbing up. Do this for thirty days, making careful assays of all the sam-

ples. Note the per cent of assays abnormally high due to particles of amalgam.

It is not sufficient to reply that what is lost in amalgam is recovered in the concentrates.

Every concentrator passes more or less of amalgam and mercury over into the tail race.

Don't scrape main plates with chisels.

No globules of free quicksilver on plates.

It is essential to keep a well-silvered surface, sticky and pasty. The apron plate may require replating every three or four months. The lower plates should wear several years. The cost of replating varies with the ore. I have found it amounts to 1 to 1½ cent per ton crushed, using a plating of three ounces silver per square foot of plate on copper weighing five pounds per square foot.

Take off every morning the excess of amalgam, but never skin it closely. I am sure this is a better method than to let the amalgam accumulate to the close of the run. This applies to all except the lip plate. Rub up with a piece of coarse cotton domestic several folds thick, sprinkling the plate with quick from a small shaking bottle. I have seen used a beer bottle with quill through the cork; but this is malpractice. Use a small vaseline jar with a piece of cotton tied taut over the mouth, and have clear, tepid water in a kettle to dip the rag in frequently. Rub the plate briskly and thoroughly, being careful every day to remove all blisters of amalgam. These blisters eat out the silver, and therefore should not be permitted to form. In cold weather they are especially troublesome. If they stick too tight for the rag, they may be gently scraped off with a piece of No. 24 stovepipe iron shaped like a flat scoop 2 inches wide. Do not use a steel chisel. Finish with a final light sprinkling from the jar and thorough rubbing with the cotton rag, then brush over with a whisk broom.

The lip plates are never softened with quicksilver, but are every morning brushed off, or, rather, scrubbed off with the broom, to clean out the sulphurets. The lips will stand a good stiff brushing daily. A 17-inch wide lip plate, plus the splash plate over it, ought to catch about one-third of all the gold recovered outside of the mortar.

At 4 o'clock p. m. and at midnight my plates are again rubbed up, but no amalgam is taken off at these times. It therefore takes only a few moments for these two rubbings. I find that the running time on a 30-stamp mill is twenty-three hours daily because of this careful plate treatment. On heavily sulphuretted ores more frequent brushing up will be necessary.

There are never any globules of free quicksilver on the plates, top or bottom. If the ore is lean, feed less in the battery, and the rubbing up is so carefully done that it never leaves drops of quicksilver on the plates.

The quicksilver fed is weighed at every shift in troy ounces and a daily record kept. Never weigh out an allowance to a millman. They know what is expected and careless work reveals itself immediately on a plate. At clean-up there should be little or no free quicksilver in the mortars around the dies.

Battery water at 55° Fahr. will give good results; 65° to 70° is preferable and high enough. It is essential not to have sudden changes. I never saw a reliable mechanical heater. Perhaps, where oil is cheap, and an even heat can be had under the boiler, it would be possible to keep the temperature uniform in a battery feed tank.

I rely upon keeping the plate room warm because I am afraid of the sloughing off of amalgam, which inevitably follows a sudden rise of 20° to 30° of the water. The automatic stoker of wood or coal must be something that does not wear pants. All the mill hands I have tried fire irregularly.

AUTOMATIC SAMPLING.—The custom of sampling tailings with a dipper by hand every half hour, more or less, has but little to commend it.

It is to the owner's interest to know exactly what the tailings assay. It is to the millman's interest to keep the tailings low.

The hand sampler will soon learn how to sample judiciously from his point of view.

Nobody can coach an automatic sampler driven by machinery.

It is absurd to take off the sample by hand from the tail of the vanner.

There are several kinds of excellent automatic samplers in use which I will not take space to describe. However the sample he taken, it should be evaporated to dryness for the assayer. Do not pour off the clear water; you may use a siphon on the excess clear water.

CLEAN-UP APPARATUS.—To clean up I use: A wooden trough 5x2x2 feet; a man with the hoe; a 49 rocker 4 feet long by 16 inches wide; a clean-up board 5 feet long by 12 inches wide, with 3-inch side rails, covered with a silver plate; a Buck and a wedgewood mortar; a small iron screen ½-inch mesh.

Into the trough throw all the mortar dirt; sprinkle freely with quicksilver; turn in boiling hot water; then hoe the mass about thoroughly with hoe and strong four-tined rake or pick, so as to break up all lumps. The dirt is then rocked out and the resultant amalgam, iron scraps and fine sands dumped upon the clean-up board and the sand washed out with a hose stream. The iron is taken out by magnet. Grind

the amalgam a few minutes in the Buck mortar; rewash on the board, giving a final bath of quicksilver in a wedgewood mortar to skim off the dross. Don't omit this bath, especially where you sell the "sponge gold." If retorting is followed by melting, the bath is not essential. To make sure there are no lumps or bits of iron, copper or brass, strain through the ½-inch screen and regrind the lumps. Squeeze the amalgam into balls through stout domestic or twilling. Chamois skin is too expensive for this purpose.

I venture the assertion that by this process two men will in two hours clean up a 20-stamp mill and leave not over \$50 in the sands.

These sands are, of course, put back in the hatteries at the following run.

I would clean up a 100 or a 500-stamp mill by the same process, except that the mixing would be done by what the macadamizing men call a "rattler" or revolving trommel. Rattler and rocker to be driven by power.

Clean-up barrels and pans flour quicksilver and thereby entail unnecessary losses of gold.

The clean-up room should have a cement floor. All wash water should pass into settling boxes or tanks.

It is not good practice to work down the headings from several mortars in one. It is better to dump all the headings from each battery into the clean-up trough.

Before hanging up the battery the pulp in it should be run down by dropping the stamps slowly. As fast as the stamps begin to bounce on the die hang them up. Whether the dies and mortar liners are removed at every clean-up will depend partly upon the grade of the ore and partly upon how hard up you are.

At the Empire mill, in Grass Valley, Cal., there is an admirable cast-iron clean-up howl, set on an angle and slowly driven by a power belt. A small cannon ball is laid in the howl and the dirty amalgam thrown in. With a constant stream of water running in, the amalgam is quickly cleaned. Trap and other strippings and sweepings are also handled by this howl.

(TO BE CONTINUED)

Zinc Ore Concentration at the Payne Mine.

TO THE EDITOR:—The Payne mine, which for ten years has been a heavy producer of high-grade argentiferous lead ore, and has paid in dividends over \$1,500,000, is now producing argentiferous zinc blende, which is recovered as a by-product in our 200 ton silver-lead concentrator at the rate of 20 tons per day (twenty-four hours) and averages 45% zinc, with 15 to 20 ounces in silver. I am at present shipping this product to the Lanyon Zinc Co. at Iola, Kan., under a freight rate of \$11 per ton, but within a month or two I will have our new magnetic separating plant completed, which will enable us to make a 60% or 70% zinc blende with 16 to 20 ounces of silver values per ton and only 2% lead and 3% iron. One particularly interesting feature about our zinc is that the iron associated with it is a carbonate or magnetic spathic iron, which is readily separated from the blende by magnets, even without preliminary roasting, in which respect it surpasses the Joplin and Colorado ores. We have in the Payne mine sufficient ore on hand—partly blocked out at lower levels and partly contained in the old stopes as a filling material—to keep our concentrator supplied for more than two years. Besides its silver-lead values this large quantity of ore will average from 16% to 20% in zinc, of which at least 80% can be saved by jigs and Wilfley tables. Until about a year ago no efforts had been made to recover this valuable mineral and the old stope fillings and waste dumps are, therefore, full of zinc concentrating material, mixed with galena and silver values, and you will readily see the great future before the property when 20 or 25 tons is produced daily as a mere by-product in the mill.

Similar conditions exist in several other properties of the camp and throughout the Slocan rich deposits of zinc have been known for several years, but it is only at a recent date that the actual market value of these ores has been discovered, a fact which reminds one of the history of Leadville and Creede camps, where zinc values were discovered after the slump in silver a number of years ago. The Slocan has for the past three years been "up against it." Not alone has silver declined beyond all expectations, but lead, which is sold to local smelters per London quotation, less \$1 per 100 pounds, reached a point where it had to be mined at a loss for the sake of its high silver values. Only a few of the high-grade properties have, therefore, been able to operate. Out of nineteen concentrators in the district the Payne in Sandon and Highland at Ainsworth are at present the only plants running steadily. With the prospects of better prices for silver, also protection for the lead industry in Canada, now under consideration by the Dominion Government, together with the addition of a zinc product, it is sincerely to be hoped that the ensuing year will see new life infused into this highly mineralized and rich section of British Columbia.

ALFRED C. GARDE.

Sandon, B. C., Feb. 8.

The Fluor Spar and Zinc Mines of Kentucky and Illinois.

NUMBER 11—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by
F. H. HARWOOD

Until recently the only worked deposits of fluorite in the United States were in southern Illinois. The supply was very uncertain, owing to water in the mines, and poor roads, it being necessary to haul the spar by team to the Ohio river for shipping to market.

The increase in the use of fluor spar as a flux by the steel mills of Pittsburgh, Pa., and the iron furnaces of Birmingham, Easley and Bessemer, Ala., and the glass factories of Indiana, resulted in opening valuable and extensive beds or veins of

protoxide and 35.2% carbonic acid. The average returns from the shipments of this mine run from 43% to 47% zinc. Trainloads are shipped from Marion to the reduction works at Mineral Point, Wis., and Joplin, Mo. The engravings on this page illustrate this mine and vicinity.

THE SOUTHERN ILLINOIS FLUORITE DISTRICT.—In Pope and Hardin counties the geological conditions are similar to those in the western Kentucky district, the several veins trending in a northeast-southwest direction. The veins so far discovered are in the southwest part of Hardin county and northeast section of Pope county. Prospecting, however, is being carried on in all parts of the above counties and discoveries made of carbonate of zinc, galena and iron ore.

Golconda is the gateway of the southern Illinois fields. Until recently this point was without railroad communication. The extension of a branch line by the Illinois Central R. R. from Reevesville to Gol-

conda, crusher, bucket elevator, four sets of jigs, and a Griffin mill for grinding. The spar taken from this mine is mixed with galena and some zinc blende. The large lumps of pure spar are separated. The rest is crushed, screened to four sizes and jigged. The capacity of this mine is 100 tons of spar per day. The shipping is all via river to Evansville, Indiana, or Golconda, Illinois, from which points it is re-shipped via the Illinois Central R. R.

The Fair View mine was worked for lead fifty years ago, but has not been in operation for fifteen or twenty years. The workings extend along a vein several hundred feet, and are in the vicinity of the Rosi Claire property. Recently the property has passed into the hands of a company, who are dismantling the old workings and erecting new buildings and placing in operation the latest improved machinery. This mine is expected to become one of the largest producers of fluor spar in the entire district.

The Zinc and Fluor Spar Mines of Kentucky.

fluorite in Kentucky. This, with the improvements made in mining in southern Illinois, removes much uncertainty as to supply.

A study of the western Kentucky and southern Illinois fields shows that most of the fluor is found in veins, which gradually widen, and at a depth of 150 to 200 feet from the surface are from 15 to 20 feet in width. A marked feature of these veins is that they continue in straight lines, most of them in a northeast-southwest direction for several miles. This is indicated by observation of the fact that many of the mines and prospects already opened are on the same line, and that their veins trend in the same direction.

The Old Jim mine is the most noted mine in the district. It is owned and operated by Blue & Nunn, and is located 4 miles northwest of Marion, Ky., and is one of the largest carbonate of zinc properties in the world. The vein in places is 68 feet in width, solid carbonate of zinc. The mine is operated or worked by the open cut system. The ore is comparatively clean, but is run through a washer before shipping. This ore when pure contains 64.8% zinc

condita will facilitate the development of the mineral resources of both Pope and Hardin counties. Golconda is located on the Ohio river, and has 1500 inhabitants, with substantial business houses and handsome residences. The following mining properties are tributary to this point:

The Rosi Claire mine is situated at Rosi Claire, Hardin county, a small town on the Ohio river 12 miles northeast of Golconda. The property is owned and operated by the Rosi Claire Fluor Spar Co. and is the best equipped mine in either the western Kentucky or southern Illinois districts. The vein was worked many years ago for lead. Shafts were sunk 100 feet in depth, but little drifting was done. The present owners have been working the property ten years. The main shaft is 300 feet deep, having four levels, the first at a depth of 100 feet, levels being placed 50 feet apart. The levels have been driven 700 feet on each side of the shaft. At the depth of 300 feet the vein of spar is 20 feet wide. The plant is equipped with two large boilers and hoisting engines, and an engine for operating the washing

The Lead Hill mine is located 4 miles north of Cave-in-Rock, Illinois. Until a year ago it was not known that any fluor spar existed in that vicinity. During the past year extensive operations have been in progress. Here a tunnel has been run, 7 feet high and of about the same width, with roof and floor in fluor spar. The output of this mine is fifty tons per day. It is owned and operated by the Hardin County Mineral & Mining Co.

The Empire mine, operated by the Empire Mining Co. of Cleveland, Ohio, promises to become an important producer, not only of fluor spar, but also of carbonate of zinc and lead. This property was worked for lead a number of years ago, the fluor spar being used to macadamize driveways and roads around the mine. The nearest railroad point to this property is Golconda, the distance by turnpike being 15 miles, to which point the mineral is being hauled for shipping.

The Grand Pierre Lead & Zinc Mining Co. own valuable mineral lands in Pope county and are operating the properties for fluor spar, lead and zinc, all

of which are found in paying quantities. The mines are in the eastern part of Pope county, in the heart of the old Government mineral reservation. Shafts are being sunk at various points, and from present indications the same fissure veins exist as in the Kentucky district. The shipping point for these mines is Golconda.

There are other good properties in Pope county, but up to the present time little development has been done owing to lack of transportation.

There are thousands of acres of land still open to the prospector. Leases or options can be obtained on favorable terms.

The Breakage of Stamp Stems.

Written for the MINING AND SCIENTIFIC PRESS by M. P. BOSS.

Notwithstanding the stamp has been the subject of so much study by so many hard-headed practical men, it seems strange that the breakage of stamp stems should have received so little attention, for the writer knows of no one, outside of himself, who seems to have given any particular attention to it, and his experience harks back to 1869. It appears generally to have been fully accepted that the stem was entitled to break from crystallization, unavoidably incident to the dropping of the stamp, for which no relief could be expected.

An analysis of the drop of the stamp will show that vibration of the stem can in a measure be regulated, and vibration is the cause of crystallization.

We will start out by saying that an absolutely straight fall on a perpendicular line and landing on an even and level bottom will generate minimum vibration and the dropping of a stamp in such a way that gives the greatest lateral deflection of the stem will cause maximum vibration. This is given as an axiom.

Rigid and fairly close fitting guides are a factor in avoiding stem deflection. Another factor is a long stamp head as against a short one, as the long stamp head yields a more acute angle generating the deflection than does the short stamp head, hence it is less effective in deflecting.

But a greater factor than these is the distance of the lower guide from the stamp head. With a given lateral pressure at the stamp head the deflection of the stem will augment as it increases in length between the head and the guide.

Referring to the cuts, Fig. 1 is a scale drawing of

an average stamp with new shoe and new die, as commonly found in the market. Fig. 2 is a drawing to the same scale, of a standard stamp of the writer's pattern. Fig. 3 is a drawing showing in an exaggerated way the manner of natural deflection when the stamp falls upon a hard rock at one edge of the shoe.

It requires no elaborate explanation to make clear that the lateral deflection of the stem must be far greater with the stamp shown in Fig. 1 than with the stamp in Fig. 2, when striking at the edge of the shoe as shown, hence less crystallization. This train of reasoning was evolved by the writer so long ago, and practically applied by him, that it has long passed from the realm of theory and speculation to that of established practice, which has eminently succeeded in its object.

Guides of wood wear too fast to admit of keeping a close fit to the stem. They also accumulate grit and wear away the stem immeasurably faster than a soft cast-iron guide. The latter under proper treatment becomes smooth and polished upon its inner surface and retains no grit.

The stamp head in Fig. 1 when fully down is only 8

inches below the guide. This necessitates that the housing be made around the stamp head instead of around the stem, as is customary with the stamp shown in Fig. 1. This is not so simple a proposition but it is very effectively done.

Recapitulating, a properly proportioned stamp of good material should run for many years without breakage of a stem, when constructed and operated under following conditions:

Guides to be rigid in place and to be close fitting at all times; stamp head to be long; stamp head as close to lower guide as it is possible to run it; stamp never to fall iron to iron; stamp never to run too fast to complete its drop before being picked up again, and proper cam alignment. If a stem breaks in midway of its length it is due to too fast running or to improper cam alignment, assuming that the guides fit properly.

Hydraulic Mining in California.

Written for the MINING AND SCIENTIFIC PRESS by W. E. THORNE.

This is a short description of placer mining with the hydraulic elevator, in ground having a small grade, so that we were compelled to have an artificial grade.

In order to do this we installed an Evans No. 2 hydraulic elevator, and worked this with a head of 250 feet with 250 miner's inches and maximum lift of 25 feet. We found when working to maximum capacity that the elevator would handle about .75 of a cubic yard per minute. We worked four men on the day shift eleven hours and three on the night shift eleven hours, an average of twenty-two hours per day. We handled about 230 cubic yards per day, at a cost of 30 cents per cubic yard. This excessive cost was caused by the shallow gravel—7 feet average depth, also by the great number of logs, boulders, stumps, etc., all of which were handled by stone hoat, employing one man and horse during day shift, with the help of two other men about half the time. Labor, 25 cents per hour; water, 5 cents per inch per hour. Without logs or boulders, and with a full head of water, we could easily have doubled our capacity.

We used 300 feet of 22-inch pipe at the upper end of the line, reducing to 1000 feet of 15 inch, then a "Y" with two 11-inch legs. On one leg we used an 11-inch "Y" with two 11-inch legs. One 11 inch line ran direct to the east, while on the others we had 11-inch gates, each with two giants, only running one giant at a time, using the gates to direct the water from one giant to the other.

Our sumps for the east were 4 5 feet deep, 5 5 feet wide by 9 feet long and gave us plenty of room. We used a grizzly with openings 6 feet by 6 inches in the clear. Our angle of upcast was 80° from the horizontal. This gave the best results.

The sluices were made 12 feet long, with four collars to each box. Bottoms of two 2x12-inch planks, making the sluices 24 inches inside. The sides were formed of one 1½x18 inches and on this one 1x12 inches, making them 28 inches deep in the clear. The sluices were cut off square at each end, then fitted together, and held by a 6-inch strip of duck over the outside of the joint. This was secured by a collar of 2x6 inches formed in the following manner: Two pieces of 2x6 inches, each 43 inches long, were cut,

to place with the bolts. Then an upright piece of 2x6 inch, 29 inches long, was placed at the side of the joint, the head and foot being secured by the block at top and bottom, as shown in the accompanying sketch, and tightened with a wedge. By this method we had but a small amount of leakage.

In taking down the sluices, in order to move to a new set, the ends of our sluices were not split, and having both ends the same width, gave us an even flow of water with a minimum amount of clogging.

Our head sluice was made the same size as the others, only boxed in 5.5 feet high, held by collars of 2x6 inches, lined inside of top with iron, where the discharge from upcast struck the top to prevent wearing a hole in it.

Our sluices were set on top of a framework of round poles 4 5 inches at small end, set 4 feet from center to center of each, and 5 feet on the side, with 2x6-inch by 5-foot spiked across for sluices to rest on, using six supports for first two sluices and four for the balance. All posts held in place by 2x6-inch by 12-foot and 14-foot struts, spiked fast to each post. Each post was set on bedrock. We used five 12-foot sluices, making a 60 foot string, with an undercurrent under the last sluice. The opening cut in the sluice was 22x13 inches, with opening between grizzly bars of ¼ inch. Undercurrent, 4x12 feet, with 9-inch drop. Hungarian rifles were placed in the main sluices 3 inches deep, and in undercurrent 1½ inch deep.

Many pan tests of the tailings showed but very small amount of fine gold—approximately 3 cents per cubic yard.

Our tailings gave but little trouble by piling up at the lower end of sluices.

We found that for a good depth of gravel—say 20 feet of fine material, with small grade—the elevator is well adapted, but like many other processes, if all is not favorable we cannot reach the maximum capacity and maintain it.

Denver, Colo., Feb. 6.

How to Treat a Belt.

The man who will put resin on his belt is either a fool or a knave. The belt is less generally understood than probably any other staple mechanical appliance. No person ever bought a cheap belt that was a good belt. The utility of belts may generally be gauged by the price paid for them, and when you induce some one to sell you a belt at a lower figure than the price first quoted, you—not the dealer—are the loser.

Often belts are made uneven and with the best of care soon get out of shape. We sometimes find a belt that ordinarily runs easy on the pulleys suddenly inclined to run to either one side or the other of the driven pulley. Either the belt has been too slack or the load has been increased from want of lubrication or other cause. In either case it will run off if you insist on applying the power. The remedy would be to either take up the belt, thoroughly oil the journals or take off the extra load—maybe a combination of all.

Then the belt may run to one side of the driven pulley when the driven shaft gets out of line with the

Sketch Showing Construction of Collar on Sluice Box Joints.

each having a block 1x6x6 inches nailed flat and flush with the ends, increasing the thickness from 2 inches to 3 inches. Three inches from the end of each strip a ¾-inch hole was bored to receive a ¾-inch iron rod 38 inches long, having solid head, with thread, nut and washer at opposite end. The strips were placed opposite the joints in the flume, one piece above and one underneath. These were drawn

driving shaft. In this case the belt runs to the low side of the pulley.

If two shafts are parallel and there is a high place on the pulley, then a belt will run to the high place; but if the shafts are out of line and the face of the pulley straight, then the belt will run to the low side or that closest to the driving shaft. The remedy would be to line up your shafting.—Power.

Silver Mining and Smelting in Mongolia.*

By YANG TSANG AOO, Tong Shan, China.

I will endeavor to describe the methods of silver mining and smelting employed by the natives in Mongolia. Modern methods have been applied there, but with little success, and, since they are familiar to most members of the Institute, I will simply mention that the failure was due to the high price of coke used in smelting the ore in modern furnaces, and to the unsuitable mill machinery employed for concentrating the galena, which is finely distributed in the ore.

The Jehol silver mines are about 45 miles northeast of Jehol, the capital of Mongolia. They embrace two mines, 5 miles apart, the Ku Shan Tze mine and the Yen Tung Shan mine. They were first worked by natives fifty years ago, about the time when mining was so flourishing in other parts of the world—for instance, in California and Australia. The upper part of the vein is galena mixed with ironstone, and is 2 to 4 feet thick. At lower levels the vein is composed of silver-lead ore running between quartz porphyry walls. Limestone, talc and black shale, colored by graphite, are found in other parts of the mine. Crystalline limestone is found 1 mile northeast of Ku Shan Tze. Granite is encountered in the Yen Tung Shan mine.

MINING—The native method of working the mines is most primitive. The same method may have been employed a thousand years ago. A small inclined shaft 4x4 feet is sunk in the vein stuff where the appearances are most favorable. Another shaft is sunk 20 or 30 yards away, for ventilation. The shaft follows the vein in zigzag fashion in whichever direction the vein appears to be richest. Timber is used only in soft ground. Where the ground is hard the roof is cut into an arch form. In some places, instead of using ladders, steps are cut in the rock, just wide enough to hold one foot. The deepest native workings are 400 feet below the surface. As the workings are above water level very little water is met with. The water in the bottom of the workings is carried up to the surface in willow buckets by boys. When the water is abundant and requires several men each shift to drain the mine, sumps 3x2 feet are made every 4 or 5 feet along the inclined shaft. Men are placed at every sump to bail up the water to the next higher sump, and so on to the surface. Although labor is cheap in China, this method of draining a mine is very expensive. When fifty or more men are employed in bailing water from one mine, it would be much more economical to use steam pumps. Formerly black powder was used for blasting. Dynamite was introduced by European engineers in 1889. Since then the miners will not employ any ordinary explosives, but only dynamite, in hard rocks. Where the ore is rich the drill and hammer are generally used for picking out the ore. Blasting is resorted to where the ore is poor. Boys carry the ore up to the shaft mouth in round, shallow willow baskets.

The miners do not receive any regular wages. The owners of the mine supply them with board and lodging, and they receive a part of the proceeds of the smelting. If the ore is worth 150 to 200 ounces a ton, each miner may get \$20 to \$30 a month. In case the ore is poor, containing less than 80 ounces a ton, it would only pay for the fuel used in smelting, and for the men's board and the explosives. At one time, when a company was formed to work the mines, the company collected 30% to 40% of the proceeds of the smelting, according to the richness of the various workings, and the contractors received the balance as payment for the expenses of mining the ore and smelting it, including the explosives, tools, fuel and the miner's wages. The company had only to look after the general drainage of the mine and the timbering of the main levels. The highest output of silver was in 1894, amounting to 140,000 ounces. The yearly average is between 80,000 and 100,000 ounces.

SMELTING—The ore as it comes out of the mine is first dressed by breaking it into small pieces, about 1½ inch square, and picking out the waste rock. The waste ore is then concentrated by washing in a spoon-like pan (Fig. 1). The water used for washing

FIG. 1.

Concentrating-Pan.

is mine water pumped from the shaft. It is allowed to run into ditches 4 feet wide and 3 feet deep,

*Trans. Am. Inst. Min. Eng.

divided into two compartments 5 feet long, and lined with timber so that the sides will not cave in. The pan floats in the water, is held by both hands and a wavy motion is given to it. The heaviest particles settle at the back or bottom of the pan. The dressed and concentrated ore is then roasted in a primitive roasting furnace. It is simply a round wall of blue bricks, perforated at intervals to allow the escape of gases, as shown in Fig. 2. A space 3 feet wide is

FIG. 2.

Mongolian Roasting Furnace.

left open for a door. When the furnace is charged full the door is built up. The bottom of the furnace is composed of wood ashes 1 foot deep. The furnace is 5 feet high and 6 feet in diameter. A layer of charcoal is first laid in the bottom of the furnace, then a layer of ore, then a layer of charcoal and another of ore, and so on till the furnace is full. It requires a week's roasting before the ore is sweet.

When cold, the roasted ore is transferred to a small smelting furnace, as shown in Fig. 3. It is built of

FIG. 3.

Smelting-Furnace used in Mongolia.

sun-dried bricks, is 3 feet high and 1 foot in internal diameter, cone-shaped, and open at the top, so that the ore and flux can be fed in. Inside of the furnace there is a protrusion, so that the blast may be directed toward the ore. The bellows consists of a square box of wood, 4x3x1½ foot, with a valve at each end, as seen in Fig. 4. It is worked by two men

FIG. 4.

Bellows.

pulling a rope on each side of the bellows. The furnace is dried by heating with charcoal the night before using. The bottom is lined with wood ashes. A layer of charcoal is first put in and then a layer of ore mixed with a proper proportion of flux, which is composed of old cupel bottoms containing about 80% of lead oxide. The blast is put on. Ore and flux are added from time to time, till there are about 100 pounds of silver-lead in the bottom. The slag is taken out through a hole near the bottom of the furnace. When there is sufficient lead in the bottom water is poured into the furnace to quench the fire and cool the silver-lead. A big hole is made at the bottom of the furnace, and the lead is extracted in the form of a round cake.

It is cleaned and transferred to a crude cupel furnace, as shown in Figs. 5 and 6. The cupel furnace

FIG. 5.

Mongolian Cupel-Furnace, Front Elevation.

is about 4 feet long, 3 feet wide and 2½ feet high, and built of rough mud bricks. These furnaces are located in groups of a dozen or more, as occasion

may require. In appearance they resemble the adobe ovens used in Mexico. The cupel proper, or muffle, is 18x12x8 inches. The cupel bottom (Fig. 6) is com-

FIG. 6.

Cupel-Furnace, Showing Cupel in Interior.

posed of fine sifted wood ashes collected from kitchen fires. A pile of ashes is dumped on the ground and made into an oblong shape. It is hardened by pressing on it with one foot. The silver-lead is wrapped in coarse paper and placed on top of the ashes. Then a muffle is made over it by forming an arch with mud bricks. Charcoal is piled on top of the muffle and ignited. Mud mixed with straw is smeared over the charcoal, leaving a hole in the top for ventilation. The complete cupellation of the 100 pounds of lead takes about ten hours. When the silver brightens water is poured on and the silver is extracted with tongs, washed, and cleaned with brushes. It is then cut up and is ready to be made into sycee-shoes, which weigh from 5 to 50 ounces each. The fineness of the silver is 995.

It is a curious fact that almost every one in the neighborhood of the silver mines has some crude method of extracting silver from galena. All the stolen ores are smelted by the wives and children of miners. The smoke from their blast furnaces often gives a clue to the men sent out to arrest the people who smelt ores in secret.

Rule for Computing Maximum Revolutions for Flywheels.

By W. H. BOEHM, member American Society Mechanical Engineers.

Methods that shorten the labor of computation are welcomed alike by the busy engineer and the bustling office man. Short-cut rules are sought not only to save time, but also to minimize the chances of error. We give a handy rule for computing the maximum allowable number of revolutions for cast iron wheels of any given diameter.

The rule is based upon the current practice of allowing a rim speed of one mile per minute for well made cast iron wheels, and so does not take into consideration the difference in strength between solid and sectional wheels.

The rule gives very accurately the number of revolutions per minute at which the mile-a-minute danger point is reached. So far as we know the method is new and is as follows:

RULE.—To compute the maximum allowable number of revolutions per minute for cast iron wheels when given the diameter of the wheel in feet. Divide the number 1680 by the diameter. This is expressed by the following formula:

$$\text{Maximum revolutions per minute} = \frac{1680}{D}$$

EXAMPLE.—What is the maximum allowable number of revolutions per minute for a well made cast iron wheel 16 feet in diameter? Here we have

$$\text{Maximum revolutions per minute} = \frac{1680}{16} = 105.$$

That is, a 16-foot cast iron wheel should never be run faster than 105 revolutions per minute.

A Correction.

In the issue of January 24th, on page 56, appeared an illustrated article on the electro-magnetic separation of zinc blende from the sulphides of iron and zinc in ores. Near the conclusion of the article in a table of assays the lead content of the zinc concentrated product was stated to be 10.60%. This should have read 0.60%. The presence of lead in considerable quantity in the zinc product would be detrimental and it would be practically lost if sent to the smelter.

THERE are those who believe that gold nuggets are formed in the gravel of streams from gold-bearing solutions passing through the gravel. Those who advocate this idea are theorists, with little or no practical experience. No miner who has actually worked placer mines for even a few months believes this, as the evidences found daily in the mine lead to a different conclusion. Moreover, if gold-bearing solutions exist in the beds of streams there is no evidence that it has ever been detected by those competent to make such determination.

DURING 1902 the mines at Almaden, Spain, produced 1375 tons of quicksilver.

DISCOVERY of mineral in place, whether payable or not, must precede location of a claim. This discovery must be made at some place within the limits of the claim as subsequently located. It need not be in or near the center of the location, but the claim must be staked in such manner that the vein shall run as nearly as possible through its center.

"Formation of Nuggets."

TO THE EDITOR:—You recently published an article on the "Formation of Nuggets," the line of argument of the article being, in fact, that the nuggets grew—increased their size "by agglomeration"—stating that "if it is admitted that the gold was originally in solution, and, after finding its way into the gravel, was reduced to the metallic state," etc.

No placer miner who actually mined and took out

or quartz still adhering to the gold, being of an almost entirely different material from the surrounding gravel and sand in which the nuggets are found, clearly showing the character of the ore of the vein or lode filling from the eroded outcropping which contained the nuggets in a metallic state, from which by glacial or other erosion the nuggets were separated and afterwards, with other eroded material, formed the deposits generally known as placers. Because once in a very great while a so-called "composition nugget" is found which in an acid bath leaves behind iron, sand and smaller nuggets or

coarse gold (lode nuggets) lodes, at the sides and heads of many of the rich gold placers. In 1894 a six-ounce placer gold nugget was taken out of the Peabody placer in Gold Run. Above this placer are the Junho, Extension and Jessie gold lode mines. On July 23, 1887, the Tom's Baby (weighing 156 ozs. 11 dwts. 7 grs.) gold nugget was taken out of the Gold Flake lode mine on Farncomb hill, which is a few hundred feet up the hillside from the rich American gulch placers, which had produced many fine gold nuggets, some of which were of heavy leaf or wire gold that had been by glacial action rolled and pounded into comparatively solid nuggets. In cleaning such "rolled" nuggets their structure was disclosed—their origin—and a search uphill from the placers led to the discovery of the wonderful veins of the rich gold ores of Farncomb hill. Specimens of Farncomb hill's crystallized, wire, leaf, moss and "chunk" gold were exhibited at the World's Fair at Chicago, and the collection under the name of the "Collingwood Collection" was awarded a medal.

Gold is heavy and settles, at the first opportunity, to the bottom of a stream, unless a stratum of stiff clay prevents its reaching the bedrock. The nuggets and coarse gold are found nearest the lode whence the gold came, when the topography has been of a nature to afford them a resting place. Farther down stream the lighter flakes and small grains have been deposited as the stream widened and the force of the current abated. Fine flake and "flour" gold is often carried many miles down stream by the force of the water, which keeps them turning over and over and sliding along with the muddy water of floods or freshets. Metallic gold, wires and thick gold leaves have also been found in chunks of lead ore; also wires in copper and leaves in iron ore in the lode mines of Farncomb hill, showing plainly that the lead, copper or iron was found or deposited after the metallic gold had been made in the veins. Such specimens are much more worthy of the real scientists' speculation and research than the few hattered and partly "rusty" gold placer nuggets that may fall under their observation. The gold in the placers came from lodes.

Breckenridge, Colo., Jan. 28. R. J. A. WIDMAR.

The Flow of Water in Open Channels.

The measurement of water in open channels is a subject which has been given much attention by Western hydraulic engineers. This has been the outcome of necessity in the construction and operation of hydraulic mining plants, and several mining States have provided extensive facilities for observing the variations of flow of water in ditches and flumes. Numerous formulas have been devised which are calculated to make the measurement of flowing water easily practicable, but the great variation in the shape, size and grade of ditches and flumes has rendered most of these formulas relatively useless under the greatly varying conditions on the same canal or flume. Ditch lines built originally with greater or less uniformity as regards cross sections become greatly varied. The flow is reduced by percolation of water into porous sections, by evaporation, and by leakage. Slides of earth and rock occur, to some extent damming up the ditch and retarding the flow. Soft sides are cut away, changing the area of cross section and the velocity.

In his treatise on hydraulic mining A. J. Bowie gives the following formula for measurement of water in ditches:

$$Q = ac\sqrt{rs}$$

Q is the quantity of water which the ditch is capable of carrying in cubic feet per second.

a the effective area of cross section of ditch, as originally constructed, in square feet.

r the hydraulic mean depth in feet.

s the fall of surface in a unit of length.

c a coefficient covering all common losses.

Owing to the number of causes influencing the flow of water the coefficient is greatly variable. It has been possible, however, by means of a table of statistics, carefully compiled from the official records of several companies owning ditches, kept during a series of years, to gain valuable knowledge of the result of these disturbing factors in the variation between the quantity of water admitted at the head of a ditch and the amount delivered at its lower end, and to establish thereby a coefficient of loss from all causes, which was found to vary from 31 to 45. In some cases, as in well constructed new ditches and flumes, where some of the losses above indicated are comparatively low the coefficient is much higher, but in ditches constructed on rough mountain sides, in rocks more or less disintegrated, the coefficients are about as here stated for ditches on heavy grades of 40 miles length and flowing from 60 to 80 cubic feet per second. For ditches of this class Mr. Bowie gives the following formula:

$$Q = 31 \text{ to } 45 a\sqrt{rs}$$

In this the same value is given each factor as in the formula previously stated, with the exception of c, which is here determined to be from 31 to 45.

TWENTY-SECOND ANNUAL REPORT, PART I PL. XXIII

PROGRESS OF TOPOGRAPHIC SURVEYING.

placer nuggets of either gold or silver will admit that the nuggets were formed in placers from solutions. There are native silver nuggets found here in certain portions of the Blue mountains, in Summit county, Colorado, about 2 miles south of Breckenridge. A silver nugget weighing almost an ounce and many smaller ones have been washed out of the river gravel in placering for gold. In every placer mine here where nuggets are found (and the nuggets of gold found in the placer mines of the Blue river gold fields range in value from a few cents up to \$495) there are also found nuggets containing slate

grains of gold, some hook-learned expert sets up a theory that nuggets were formed from a solution or agglomeration in the placer where found. In a residence of nearly eighteen years in Summit county, Colorado, which is the hanner gold nugget producer of this State, I have never seen any of the iron-gold-sand "agglomerated placer nuggets," and have heard of but one—which was supposed to have been a chunk of rusty, hard amalgam. The theory that the gold and silver nuggets found in placers have come from nearby lodes is amply carried out in the Breckenridge gold belt by the discovery of gold, and

Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 3, 1903.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

SELF-DUMPING MINE CAGE.—No. 719,258; F. A. Ray, Columbus, Ohio.

In self-dumping mine cage, combination of fixed guide standards 1, lifting frame arranged therein and adapted to be elevated vertically, guide standards having inclined recesses 2 and inclined rails 4 leading from lower portions of recesses, of cage comprising platform 13 and standards 15 and 12 mounted to swing in lifting frame, shaft 16 on which upper portion of cage is journaled, elongated truck or wheel frames mounted on ends of shaft and wheels journaled in opposing arms of frame, wheels adapted to embrace opposite sides of standards 1 and pilot guide wheel journaled in upper end of each frame.

FILTER AND EXTRACTOR PRESS.—No. 719,438; J. G. Crossman, Watford, England.

Improved filter and extractor press comprising frame supporting sectional filter, hollow trunnions upon which frame is pivotally mounted, hollow press frames forming compartments of filter and holding material to be treated, corrugated intermediate partition plates disposed between press frames and carrying filtering fabric on either side of corrugated plates, annular bosses on press frames externally of filtering area of plates, bosses forming when several press frames and intermediate plates are closed together, continuous inlet pipe for conveying material to be treated to compartments of filter, two similar bosses on intermediate plates forming when parts are assembled, continuous inlet and outlet pipes for liquor to be treated, passages in one set of bosses leading from one pipe to one side of intermediate plate and passages leading from other pipe to other side of intermediate filter plate, connection from liquor inlet and outlet pipes to one hollow trunnion and connections from pipe formed by bosses of compartment frames leading to other hollow trunnion, means for allowing plates and frame of filter to be

separated or assembled, and means for securing them in position when assembled.

CHLORINATION BARREL.—No. 719,664; J. B. Hefernan, Colorado Springs, Colo.

In chlorination barrel series of pipes having numerous perforations throughout their lengths, arranged in parallel and lying close to inside wall of barrel, and having suitable connections with outside fluid pressure system.

APPARATUS FOR GENERATING STEAM FROM HOT SLAG.—No. 719,520; H. A. Seymour, Washington, D. C.

Combination with steam generator, of reciprocating and rotary plunger provided with slag receptacle and adapted to feed charges of hot slag into generator and to discharge them into body of water contained therein.

DREDGING AND EXCAVATING MACHINE.—No. 719,567; J. J. Conlin, San Francisco, Cal.

In dredging and excavating machine, combination with movable platform, dredging wheel mounted thereon for rotation in upright plane, means for raising and lowering platform, comprising fixed nuts in platform on opposite sides of axle, screw rods working through nuts, fixed bearings below movable platform in which lower ends of screw rods are fitted to rotate, power-driven shafts mounted on platform and gears connecting screw rods with shafts to rotate rods in unison, and adjustable counterbalance on movable platform.

GOLD SEPARATING APPARATUS FOR DREDGING MACHINES.—No. 719,582; J. H. Gray, San Francisco, Cal.

The combination with revoluble cylindrical screen

of plurality of aprons beneath screen having inclination laterally outward in opposite directions from ridge situated longitudinally under center of screen, an equalizing bar on lower end of each of aprons, adjustable gate between ridge and bottom of screen, means for setting and holding gate at varying angles in either direction from central position.

DRILL SHAPER AND SHARPENER.—No. 719,874; J. Retallack, Victor, Colo.

In a machine of the class described, set of radially movable clamping dies having V-shaped ridges in combination with independently movable trimming tools guided upon clamping dies and having V-shaped recesses engaging ridges, also engaging edges of tool that is being operated upon.

PROCESS OF PRODUCING ALUMINUM.—No. 719,698; H. F. D. Schwan, St. Louis, Mo.

Process of reducing aluminum compound, which consists in subjecting compound to action of reducing agent, of which sulphur is component, at temperature sufficient to effect reduction.

CINDER OR HOT METAL CAR FOR BLAST FURNACES.—No. 719,706; E. A. Weimer, Lebanon, Pa.

A cinder or other car having ladle provided with trunnion at each end, elongated seats or bearings on which trunnions are supported, toothed wheel on one of trunnions and revoluble member engaging toothed wheel; in combination with motor connected to member to impart lateral and revoluble motion to ladle.

Mining Summary.

Specially compiled and reported for the
MINING AND SCIENTIFIC PRESS.

ALASKA.

The steamship Valencia sailed from Tacoma, Wash., Feb. 8th, with 100 men, 75 horses and 400 tons of provisions, destined for the Mazina placers and the copper district 185 miles inland from Valdez. They are being sent by the Chitina Development Co., controlled by R. Biel, J. D. Menach and H. Meyer, who own 200 claims in the Mazina district.

ARIZONA.

COCHISE COUNTY.

The Arizona C. M. & S. Co. is preparing to work a group of claims near the Black Diamond Co.'s claims, 18 miles from Tombstone.

The Calumet & Pittsburg, near Bisbee, have their pumps in operation.

The plant of the Dragoon Copper M. & S. Co., near Tombstone, is in operation. The shaft will be sunk to the 750-foot level.

The Black Diamond Co., near Tombstone, has blown in its smelter. The Copper Crown Co. is making arrangements to further develop its claims and will put in machinery and use drills on the 275-foot level.

COCONINO COUNTY.

J. B. Giraud of the United Gold & Platinum Co. says the company will build a smelter below Beaver Falls, 9 miles below Supai. The water at Beaver Falls will be utilized for power by means of a turbine motor. An electric railroad will be built from some point on the Santa Fe or Grand Canyon Railroad to the plant.

GILA COUNTY.

The Old Dominion smelter at Globe closed down this week, having exhausted the available supply of ore. No ore has been hoisted for two months on account of water, but will resume by the 15th inst. Grading has begun for the four-compartment shaft at a point 600 feet north of the present shaft.

C. E. Force, secretary of the Gila-Pinal M. Co., formerly the Bohtail mines, says development machinery will be put in at their Mineral creek mines, near Globe. The shaft will be sunk 300 feet. A road is being built to the new shaft and grading being done for the engine and boiler house.

A. C. Slehoth, superintendent of the Arizona & Hancock M. Co., on Mineral creek, near Globe, says sinking will be resumed. The shaft, down 250 feet, will be sunk to 450 feet, and the ground below 250 feet opened up by levels.

The Hancock & Arizona C. M. Co. will take up the option which they hold on a group of eighteen claims in the Pinto Mountain district, 16 miles southwest of Globe. The shaft is down 250 feet and in sulphide ore, which assays 10% copper.

GRAHAM COUNTY.

The Detroit C. M. Co. at Morenci propose to increase the capacity of their concentrating plant from 500 to 800 tons. To determine the machine to adopt for treating the ore after it comes from the jigs, several styles of concentrators are being tried out. After the ore is sized, passing through jigs, it is ground into pulp and carried into a tub divided into four equal compartments. The tub is fed by a set of revolving pipes, through which the ore for test is sprayed, giving each compartment of the tub an equal quantity of the same quality of ore. From each compartment in the tub each machine receives its feed.

A strike is reported on the Sapphire mine, adjoining the Emerald at Morenci. A tunnel was driven to cut the Coronado dike, and at a point in 150 feet an 8-foot lead of sulphide ore was struck which assays 7% copper.

MARICOPA COUNTY.

E. Crimmon of Lehl is developing a group of claims 12 miles northeast of Mesa City, on the south side of Salt river. The shaft is down 50 feet and this spring power will be obtained from the Highland canal.

Secretary Nickerson of the Electra M. & M. Co., near Phoenix, reports to the company one shaft down 60 feet and the other 250 feet, with a drift 35 feet west and a drift 30 feet east on the 150-foot level, and a drift 90 feet on the 210-foot level west. The ore runs 2 to 5 feet wide, and an average of thirty-one assays taken across the ore gives \$17 per ton.

The Wickenburg M. & S. D. Co. has been incorporated at Wickenburg. G. Bellairs, F. Garcia, C. B. Burson are the officers. They have bought the La Union mine, near the Grijalva, and will start development work this month. A

30-foot shaft on the ledge shows a 2-foot vein at the bottom, carrying gold values. An option has been taken on the Golden Banner group, north of the Vulture.

Superintendent Franklin of the Uncle Sam M. Co., in Blue Tank district, near Wickenburg, says the shaft will be timbered and a gasoline hoist installed and sinking continued to the 500 level.

MOHAVE COUNTY.

J. C. Nohle will work the Climax mine, Union basin, owned by J. Dundon, of Corhat. The shaft is down 100 feet.

E. T. Loy is putting up a hoisting plant on the Mother Lode mine, at Chloride, and sinking the shaft will be resumed.

The Gold Standard M. Co., recently organized to work claims at the south end of the Chemechevis mountains, has suspended operations. It is said the shaft work done so far has averaged \$27 per foot in cost.

In the Wallapai mountains the Enterprise M. Co. is developing a group of prospects and the main shaft is down 110 feet. A parallel ledge has been cut by tunnel at a higher elevation. There are six claims in the group and the company has bonded the Iowa, Texas and Big Six mines, says Superintendent L. White.

PIMA COUNTY.

The American Smelting & Oil Co. is organized at Tucson to absorb the Sunshine Paraffine Oil Co. and the smelting company. L. V. Navarro is president.

PINAL COUNTY.

The Golden Pinalades group of mines, west of Casa Grande, has been sold to Boston men.

Superintendent Brownell of the Producer M. Co., near Casa Grande, will put in a hoist and an air compressor and machine drills. Brownell has bought the Jack Rabbit mine, and will begin development this month.

YAVAPAI COUNTY.

(Special Correspondence) — The Cash mine, near the summit of Los Prietas range, 12 miles southeast of Prescott, is developed to a depth of 700 feet, having two shafts 500 and 700 feet respectively, and a third shaft sinking. The ore is a heavy sulphide with relatively small amount of silica. Zinc blende is abundant, and values chiefly in gold. The ore is crushed in mortars with low discharge. The pulp passes over 12 feet length of silver-plated copper plates, in three 4-foot sections with 1-inch drops. Concentrating tables separate the zinc and silica from iron, lead and copper sulphides, there being five tables to ten stamps of 900 pounds each. The mill crushes forty tons daily through 40-mesh screen. A large percentage of the gold is obtained by amalgamation and two separate shipping concentrated products obtained. H. Blauvelt is superintendent.

Prescott, Feb. 7.

(Special Correspondence) — The Poland mill at Poland is running twenty stamps, banding eighty tons of ore per day.

The Express group of Poland has a drift 500 feet, which gives them 450 feet depth on the vein 8 to 18 inches wide, running \$25 to \$75 per ton. They have shipped twenty-five carloads in the past three months to the smelter at Valverde and are now raising to the surface. The raises will be used as a shaft when finished; working thirty men; M. Hoveck, superintendent.

The Poland Extension M. Co. employs thirty men. The Rookery tunnel is in 610 feet, with a drift on the ledge 375 feet. On the Fitzhugh Lee the shaft is down 110 feet, with 540 feet of drift on the vein, which averages 18 inches and runs \$18 in silver, lead and gold. The Heller tunnel is in 327 feet with a winze 50 feet, in 5 feet of ore worth \$9 gold, copper and silver. The same company is running a tunnel on the Vassar group. The lower tunnel is in the ledge. The upper tunnel is in low-grade ore, no waste. It runs \$11 in gold, silver and copper; John Gray, superintendent.

The Oriental M. Co. at Providence owns twenty-five claims, including mill-site. The claims are in three groups. The tunnel on the Lottie is in 3300 feet and is to be 6000 feet, and will gain a depth of 1100 feet. Work has been suspended since last April, but the company is now making contracts for work. They will erect a mill at mouth of tunnel when completed. There are several miles of drifts in the property. This company is also operating the Postmaster group in Big Bug canyon, where they have a mill with thirty-five to forty tons capacity. Crushers and concentrators are used in the mill.

Poland, Feb. 9.

President C. J. George has made final payment on the McKinley and Vassar groups of claims, near Prescott, for the Poland Extension Co., near Phoenix. They have fifty men at work. A mill

will be erected for the reduction of ores of the Poland Extension and the two adjoining claims of the Gold & Copper Co., of which C. J. George is president. A gasoline hoist will be put in next month at the Fitzhugh Lee, one of the claims of the extension. On the Poland Extension proper a crosscut has been run 500 feet and from that point drifting done for 600 feet. The Extension Co. has eighteen claims in four groups. John Gray is superintendent.

At the Sloan mine, located in Grapevine district south of Yeager canyon, near Jerome, the Yeager Canyon C. Co. report having struck a body of ore carrying gold, copper and silver, at a depth of 800 feet.

Eighty stamps are dropping in the mill of the Congress mine, near Wickenburg, crushing an average of 300 tons daily.

CALIFORNIA.

AMADOR COUNTY.

At the Onelda mine, near Jackson, the shaft is down 2200 feet. A small hoist has been set up at the 2000 level, and the rock hoisted from below is dumped into skips and sent to the top by the regular hoist. The recent rains have necessitated three hours extra pumping daily.

CALAVERAS COUNTY.

The Lloyd gravel mine at Central Hill, 4 miles west of San Andreas, is being operated by F. F. Ames of San Andreas.

The Buffalo mine in Chile gulch, near Mokelumne Hill, has been bonded to D. M. Reardon of San Francisco for nine months for \$30,000. This property comprises 160 acres of patented land. There is a mile of gravel channel.

Manager F. F. Hammon of the Hammon & Carnduff Co., prospecting bonded ground in and along the Calaveras river, near Jenny Lind, says they will build a dredger and begin working the gravels.

EL DORADO COUNTY.

The El Dorado C. M. Co. has bought several additional mining claims near Georgetown.

An aerial tramway will be built by the Eureka Slate Co. from Kelsey to Placerville for transportation of slate from the Eureka slate quarry.

INYO COUNTY.

The Ratcliff mines at Ballarat, a group of twelve claims in Pleasant canyon, Panamint mountains, are reported sold for \$250,000 to Eastern men. One vein, 60 feet wide, is of milling ore. M. Garbut of Los Angeles is manager.

KERN COUNTY.

The Charter Oil Co., a lessee of the Queen, near Bakersfield, will resume, O. S. Hickey having a contract to deepen the well.

The Gilt Edge Oil Co., in Sunset district, will sink its well to 1700 feet, being down 1500 feet.

The New York-Pacific Oil Co. will drill in the San Emidio district, on the Los Lohos ranch, 7 miles southeast of Sunset.

MONO COUNTY.

In West Walker district, near Bridgeport, at the Cuban Prince mine, owned by F. Owens and R. Terry, they are driving a 100-foot tunnel — Owens will start sinking a shaft on the Blue Bird in April.

NEVADA COUNTY.

Superintendent J. C. Roberts, at the Peabody mine, near Grass Valley, has men at work timbering the drain tunnel. A holler will be put in and pumping started.

Several tons of ore, taken out by H. Harris & Co. from the shaft at the Union hill, near Grass Valley, 1000 feet below the main works, last week gave returns at the Orleans mill of \$13 per ton.

ORANGE COUNTY.

It is locally reported that a smelter is to be built at Newport, 8 miles south of Santa Ana, on the coast, with the intention of establishing a market for custom ores.

PLACER COUNTY.

The Peckham hill tunnel of the Big Channel Con. M. Co., in Snyder canyon, near Forest Hill, is in 400 feet, says Superintendent Ramsdell, and it is expected to cut the channel in 400 feet more.

G. Bisbee has a full head of water and is working his claims on point Lookdown and at Shenanegan hill, near Forest Hill.

PLUMAS COUNTY.

R. E. Carswell, secretary of the Cataract G. M. & P. Co., operating the Indian Bar Con. mine on the North Fork of Feather river, 3 miles below Rich Bar, Quincy, says the company has 10 miles of old canal along the canyon of Yellow creek to the North Fork, which will be repaired to carry water for hydraulicking. They have bought 800 acres of gravel channel.

Monitors will be used in washing gravel to the elevator being put in and an electric plant will be installed.

RIVERSIDE COUNTY.

W. Haarlo, Jr., president and manager of the La Crescenta M. Co., below Needles, on the Colorado river at Riverside mountain, says the company will put up a smelter at their mines.

SANTA BARBARA COUNTY.

The Loma Oil Co. of Los Angeles will begin drilling for oil on the Fox ranch at Graciosa next week.

SHASTA COUNTY.

The ending of the strike has brought many men to Keswick in search of work, when there has not been enough for the union and non-union men already there. The Mountain Copper Co. is not discriminating against the strikers, but is not reopening the smelter full blast. Of five furnaces only one has been blown in. The pumping plant, converters, foundry, machine shops, three brick machines and eleven rotary roasters are still idle; one railroad crew is running and no ore is coming down from the mine, and the smelter will not be in complete operation until shipments are made from the mine.

A strike of ore was made last week in the Central mine, in the Old Diggings district, near Redding, says Superintendent A. A. Anthony, in the lower tunnel. The ledge is 300 feet below the surface.

The general and assay offices of the Balakiala mine, near Kenrett, were destroyed by fire on the 9th inst., says Superintendent W. W. Adams. Loss, \$1000.

United States District Attorney Woodworth and Special Agent Pryor of the General Land Office are at Redding on business concerning the damage to Government timber by smelter smoke in the vicinity of the Mountain Copper Co.'s plant at Keswick. The company has assured the representatives of the Government of its readiness to meet every just demand upon a proper showing of the actual damage incurred. J. J. Pryor, the special agent, has recommended that the injunction suit be dismissed and that the Government take action to secure damages.

SIERRA COUNTY.

The Sierra Buttes mine, near Sierra City, has closed down and forty men are idle because the company refuses to discharge the boarding house cook.

SISKIYOU COUNTY.

A strike is reported in the Advance mine on the Salmon river. C. White, L. Michelson and J. Davison located the claim last July. They found the ledge in the face of a drift they were driving, and in three days time took out \$2800 with a hand mortar.

A strike of free gold ore was made last week in the drift in the Advance mine, on Chinagulch, in the Salmon River country, near Sawyer's Bar. The mine is owned by C. White, L. Michelson and J. Davison. They report having pounded out \$2800 in three days with a hand mortar. The Advance until recently was worked in open cuts, one of which is 85 feet deep. The ledge in the face of the drift shows 3 feet wide.

TRINITY COUNTY.

The report that the Bully Chooch mine has been closed down on account of a strike is incorrect. The plant was closed by reason of the last heavy storm. There is 10 feet of snow on Bully Chooch mountain, where the mine is located, and the ditch that furnishes the mill with water is frozen up. W. B. Gester, general manager, says that when weather conditions are such that he can proceed with the work he will do so with a full force.

The east end of the Unity M. Co. dam on the east fork of Stewart's fork, near Weaverville, went out during the recent storm. The dam was 40 feet high and built four years ago.

L. H. Willis reports a good clean-up on the Hansen ranch placer claim, near Weaverville, which he has been operating this winter. It is reported a prospector recently picked up a nugget worth \$408 near the mine.

A. Mansfield, operating the Gold Bug quartz mine on Karick gulch, near Weaverville, a quarter of a mile from the Mason & Thayer mine, says several prospect holes have been sunk on the ledge, uncovering a shoot of ore which assays \$60 per ton. The ledge is 20 feet wide with 2½ feet of pay. He is building an arrastra and also drifting under the old town of Canyon City, where he is finding coarse gold in paying quantities.

TUOLUMNE COUNTY.

The Ryan-Mackay copper mine, west of the Jumper mine at Stent, was bonded last week to the Payne Smelter Co. of San Francisco. The two shafts will be

unwatered to determine at which point operations can be best conducted. A hoist and other development machinery will be installed, the shaft widened to double-compartment and sunk 500 feet. The Sierra Railway Co. will run a switch to the mine from a point below Jamestown and bunkers will be erected. The ore carries values in gold and silver, as well as copper.

At the Longfellow mine, Big Oak Flat, a shoot of ore has been struck carrying \$30 per ton in gold, says F. H. Partington superintendent.

The Century G. M. Co. of West Virginia has bought the Gagnere quartz mine and millsite near Tuttle town. — L. Kahl has bought the Darrow one-third interest in the Beynon and Darrow placer mine on Mormon creek. — The Vivian mining claim has been bonded to W. S. Wilhelm for \$13 000, payable before Dec. 4 1905. W. S. Wilhelm has bonded the Concord quartz mine for \$10,000.

The mill at the Mount Jefferson mine at Groveland is shut down pending repairs, says Superintendent J. H. Gilmore.

YUBA COUNTY.

O. H. McConoughy, of Chicago, superintendent and owner of the Crystal mine, near Brownsville, has men at work reopening the mine.

COLORADO.

BOULDER COUNTY.

Manager C. F. Lake of the Boulder County M. & M. Co. at Cardinal, in the Grand Island mining district, 3 miles from Eldora, says it is planned to enlarge the mill to 100 tons daily capacity. Work will be resumed on the 3000-foot crosscut tunnel, which will cut the vein at a depth of 1700 feet. A compressor plant, machine drills and aerial tramway will be installed. The vein carries a shoot of smelting ore, with gold and silver. The average for the entire vein is \$10 a ton.

The Alaska tunnel in Ward district will cut the veins on the Utica Hill G. M. Co. claims at a depth of 1200 feet. The mouth of the tunnel is 3000 feet from the Utica Co. shafthouse. A body of high-grade ore has been cut, and the opening of the Utica by this tunnel will reduce the cost of mining by the Utica 45%, it has been estimated. Their ores are treated by cyanide.

A concentrating mill will be built at the Hooser at Sugar Loaf this spring to treat tungsten ore.

CHAFFEE COUNTY.

The Salida G. & C. M. Co., incorporated to operate the Sedalia copper mine near Salida, will install a 100-ton mill to treat the ore by leaching process, independent of the smelters.

CLEAR CREEK COUNTY.

Reiley & Haggart have opened up 3 inches of ore in their lease on the Egan on Democrat mountain, near Georgetown, which mills without sorting 250 ounces in silver per ton.

E. W. Williams has bought the Kohlnoor and Donaldson properties above Idaho Springs, including the Champion and Trio lodes and the mills and water power on Clear creek above Idaho Springs. Work has begun on the Trio through the tunnel, which will cut the Champion when driven 200 feet farther at a depth of 800 feet.

A body of high-grade ore has been opened in the lower level of the Sunhurst mine of the Red Oak Co., near Georgetown, in an upraise. This strike is 300 feet lower than the main level, where the upraise is connected between the main level of the Sunhurst and the Sceptre tunnel. The ore from the Sunhurst will be taken out that way to the tramway.

The Mendota mine and mill, near Georgetown, J. Old manager, says the zinc product for the last month equaled that of the concentrates of lead, silver and gold. Shipments are made daily from the mill. The zinc is shipped to the smelter at Canon City.

At Yankee, Manager Seeman of the Yankee Con. M. & T. Co. in driving a tunnel on their Lomhard extension claim 1500 feet below the upper tunnel to prospect for the Lomhard-Polaris vein, cut the ore body at 110 feet last week. With this additional find the company will increase its milling facilities.

CUSTER COUNTY.

E. Morrison, working a group of claims 12 miles southeast of Westcliffe, on Look-out mountain, in Boneyard park, says on one of the claims he has opened a 7-foot vein between schist walls which carries uranium at a few feet depth from the surface.

There are 100 men at work in and about the Bassick mine, near Querida. Manager A. W. Warwick says a new ore body has been found in the 1600-foot level, carrying gold and silver values. A cyanide

mill and an electric-light plant are being installed.

FREMONT COUNTY.

The shaft of the coal mine at Rockvale has been repaired and operations resumed. The entrance of the emergency outlet is being cleared.

GILPIN COUNTY.

Shull & McLeod, working the El Dorado mine at the head of Leavenworth gulch, near Central City, are taking out smelting ores from a depth of 100 feet, which assay \$70. They are shipping milling ore.

Manager M. D. Draper reports finding free gold ore in the 330 foot west level of the East Notaway mine, near Central City, which is being worked by the Town Topics G. M. Co. Regular shipments are made to the smelter at Golden.

A Nevada mine company will operate the Ute mines on Quartz hill under a lease and bond to T. and J. Chappel, J. and K. Eva, A. Curnow, N. Tregear and J. Trembath. The main shaft is down 400 feet.

The Brooklyn mine, near Lake View, south of Central City, has resumed. From the bottom of the shaft down 600 feet crosscuts will be driven north and south. The property is being worked by R. Cleary of Denver, the owner, with J. Faulkner, superintendent.

The West-Calhoun and Jefferson mines in the Quartz hill and Russell gulch district, have consolidated. The property is controlled by the Gold Mining Investment Co. and will be cut by the tunnels now being run in from South Clear Creek, at depths of 2000 to 3000 feet.

The water is being lowered in the Bates-Hunter mine on Bates hill in Gregory district and a number of sub-lessees will begin work in the lower levels. Other lessees are at work above the 300-foot levels, and they are taking out smelting ores as well as ores for amalgamation. The group is operated by H. Becker, under a lease from the Eastern owners.

Russell Gulch parties are working the Gem property on Quartz hill and taking out ores from a depth of 150 feet. A recent shipment gave values of five ounces gold per ton. Among the regular shippers in this district is the Hamlet, worked by the Hillside M. Co. under a sub-lease. Ores are taken out from three levels, both of milling and smelting grades.

During the last week of January there were shipped from the Black Hawk depot of the Colorado road 111 cars, or 2220 tons of smelting and crude ores, tailings and concentrates, making a total of 361 cars, or 7220 tons for January, and in comparison with the same month of 1902 an increase of 1200 tons.

The St. Louis-Justice mine in Lake district is being operated under lease by Valero & Co. of Colorado Springs, and they have sunk the shaft to 700 feet. On the 500 and 600-foot levels they are taking out both milling and smelting ores, the last lot of smelting grade going three ounces gold per ton at the sampling works.

Leidinger & Co. are taking out surface ores from the west end of the Prompt Pay mine in Russell district, and it is being sent to the stamp mill.

Manager J. McMillen of the Ann Rutledge G. M. Co., operating the North Star mines in Vermilion district, 6 miles west of Central City, says the North Star shaft, through which the group will be worked, is down 150 feet and will be sunk to 400 feet.

The Colorado & Tellurium M. Co. have a lease and option on the Freedom and Bueno mines in Gregory district for three years for \$35,000. W. W. Emmett is superintendent.

Denver and Eastern men interested in the Ann Rutledge G. M. Co. have resumed operations at the North Star group in Vermilion district, 6 miles west of Central City. The shaft, down 125 feet, will be sunk 300 feet deeper this winter and other development work done. J. McMillen is superintendent.

C. Pishon and D. Zancanella, working the Traction mine on Missouri flats, near Russell gulch, at a depth of 100 feet made a shipment last week of 1½ cords to the Gilpin mill and have a shipment of sulphide ore to send to the sampling works.

GUNNISON COUNTY.

The Maid of Athens, near Pitkin, is shipping regularly. A 500-foot tunnel reaches the ore body, which is being worked in both directions.

The Beaver M. & M. Co., operating a group of claims on Cameron mountain, in Tincup district, are shipping. The upper workings show a strong vein of ore which assays \$15 in gold, says J. W. Carpenter, superintendent and manager.

The Wilkinsburg M. & P. Co. is operating in the Last Chance gulch in the Gold Brick district, near Gunnison.

T. Sharpe is developing the Calumet lode above Ohio City, and last week shipped ore averaging \$60 per ton, gold.

The Homestake group in McIntyre gulch, adjoining the Cortland mine, is being developed by S. M. Tarkington, et al., of Ohio City.

The Golden Age group, owned by M. Kelleher at Vulcan, has opened up in one claim a 5-foot vein, between schist and porphyry walls, and carries copper oxides with \$5 in gold and a few ounces silver per ton.

HINSDALE COUNTY.

(Special Correspondence). — The new shaft being sunk on the Ute & Ulay is down 375 feet, the contract calling for 400 feet, when a sump 20 feet deep will be sunk, a station cut at 400 feet and drifting commenced.

The Red Rover mill is running steadily, turning out a good grade of lead concentrates, which are shipped to the Salda smelter. This is a Boston company. D. A. Farrell is manager.

The owners of the Isolde, in Burrows Park, have a bond and lease on the Inez & Hollister, adjoining their property. Rich ore has been mined from the Isolde and considerable shipped from a small stope near the surface, which was worked up to the side line. The vein passes into the Hollister ground.

The Hidden Treasure Co., near Henson, are developing and blocking out ore, but owing to cold weather and shortage of water their 100-ton concentrator is idle.

The concentrating mill of the Henson Creek Lead Mines Co., near Capitol City, is nearly completed, but will not be run until spring. P. T. Hewitt is in charge.

Watkins & Kilvert, who have a lease on a block of the Golden Fleece, also on the mill of the same company, are running the latter whenever they can get ore hauled from the mine. The roads are in bad condition.

Mr. DeRemer, inventor of the De Remer water wheel, recently inspected the power plant of the Red Rover Co., where one of his wheels is in operation, and made some changes in the nozzle, increasing the power materially. The Tobasco Co. at Sherman also have De Remer wheels in their plant.

The Hotchkiss Mountain M. & R. Co., owners of the Black Crook group on Hotchkiss mountain, have twenty men employed on development work.

Lake City, Feb. 7.
The Inez-Hollister group in the Burrows Park district has been bonded to the Dupre G. M. Co. of Lake City for \$80,000. This secures to the Dupre Co. the ground through which the Isolde vein may be reached at depth. Development continues on the Isolde, but with the opening of spring more men will be put on and the Inez tunnel driven ahead and made the main working tunnel.

HUERFANO COUNTY.

The Hesperus G. & C. D. Co. has incorporated at Walsenburg; F. E. Clary, J. B. Hawes, A. M. Nye, F. W. Kinney. M. Bird, of Walsenburg, is manager. The company will develop property in the Ojo and Blanca districts.

LAKE COUNTY.

From the Morocco shaft of the Home Extension M. Co., near Leadville, Manager A. M. Galles is shipping two carloads a day of manganese, which nets them \$3 per ton.

H. C. Burlett, operating the Hopkins mine on Mount Sheridan, is taking out lead ore which he is storing and will begin shipments in the spring.

The lead-zinc sulphide dump of the R. A. M., near Leadville, is being shipped to the Empire Zinc Co.'s works at Canon City at the rate of seventy-five tons per day. A large tonnage is also coming from the mine, principally zinc sulphide shipped to Belgian smelters.

MINERAL COUNTY.

Operations have begun on the Union group, owned by the Captive Inca Co. at Creede, and Manager W. Boyle has men sinking a new shaft north of the United Mines and on the Amethyst vein. The shaft will be sunk 600 feet.

OURAY COUNTY.

The Newshy M. & M. Co., near Ouray, is opening up a body of high-grade ore near the breast of the 1600-foot tunnel. Shipments will be resumed. All the low-grade ore from the Newshy is being placed upon the dump pending the building of a mill.

SAN MIGUEL COUNTY.

The management of the Alta M. Co., near Telluride, has issued a statement showing the production of the Alta mill for the past five months. The mill produced 1610 tons of concentrates of an average value of \$33 35 a ton. This output will be doubled after March 1. The value of the ore, 1609 tons, was \$53,666 at the mine.

Lessees White and B. Chadwick, on the Blue Lake mining claim in Bridal Veil

basin, near Pandora, are driving a tunnel on the Blue Lake vein, being in 160 feet. They have opened up 18 inches of gold and silver ore, assaying \$200. A vertical depth of 60 feet from the surface is attained by the tunnel. The Blue Lake group comprises seven claims.

SAN JUAN COUNTY.

The Golden Eagle mine, near Eureka, is bonded to F. S. Shaw of Chicago for \$60,000.

The Pearl mine on North Mineral creek, 5 miles from Silverton, has been leased to T. W. Miles, M. A. Tenny et al. of Denver. The property is developed by a 240-foot crosscut and drift, which opens up two shoots of silver ore aggregating 13 inches in width.

The Big Five M. Co. is receiving bids for the driving of 1000 feet of tunnel on their mines near Howardsville. On the Union, which heads north from Howardsville into Tower mountain, 500 feet will be driven, and the other 500 feet will be run in the new tunnel heading east into Galena mountain.

The lower tunnel to cut the Champlon vein on Sultan mountain, near Silverton, is in 760 feet. Patterson & Johnson are the owners.

J. D. Wells, operating the Pearl mine in Shofly basin, a mile from Burro bridge, near Silverton, has opened up the vein with a 200-foot crosscut and drifted on it for 50 feet. The vein shows two streaks of ore, 4 inches wide and 9 inches wide, carrying silver, zinc and gold.

SUMMIT COUNTY.

The Mono group of three claims on Mineral hill, near Breckinridge, owned by J. Miller and F. Brown, is in ore. The vein was cut after running a crosscut 400 feet, opening up a body of lead, gold and silver.

The Marcelle M. & M. Co., near Montezuma, is driving its tunnel both north and south on the vein cut last month. On the north drift, where it is supposed to be barren ground, two streaks of smelting ore are showing in the face and they are approaching each other.

TELLER COUNTY.

Lessee Darnell, operating on the War Eagle mine, Cripple Creek, reports a strike 4 feet east of the main vein and beneath the shaft house. A drift has been run on the ore for a distance of 15 feet, and ore averaging \$30 to the ton opened up. A winze has been sunk from the 60-level in ore.

M. Hoskins et al. have a lease on block 16 of the Roxanna mine, Cripple Creek district. Patton Bros. have a lease on the North Star block of the same company. Lessees on the Climax No. 1 of the Little Puck Co. are sinking and drifting with machine drills, and ore is being saved from both shaft and drifts which assays \$25.

The Last Stake G. M. & L. Co., adjoining the Gold Coin, Cripple Creek district, has its shaft down 600 feet and cutting a station, after which crosscuts will be started.

H. L. Niedringhaus, manager of the Hilderbrandt G. M. Co., owning a group on Grouse mountain near Cripple Creek, says he will install a plant of machinery. The shaft is down 400 feet and development will be extended. Pay rock has been found on several levels of the mine.

N. Ostron & Co., leasing on the Ramona on Bull hill, Cripple Creek, report the old workings having opened a new vein, showing 2 feet of \$40 ore.

Hoisting ore has begun through the new three compartment shaft of the Zenobia mine of the Stratton-Cripple Creek M. & D. Co., on Bull hill, Cripple Creek, says Manager W. G. Rice.

The Hanover Co. has granted a two years' lease on the Hanover mine on Bull hill, Cripple Creek, to Deadwood men, and G. W. Tynan of Independence, Colo., is superintendent. A shaft will be sunk to 200 feet.

Nine sets of lessees are operating the Acacia ground at Cripple Creek. Lessees Wyatt & Sharp, on the Morning Star, last week made a shipment of ten tons of three-ounce gold ore from the Pinnacle vein in the 250-foot level east of the shaft, the values being principally in the screenings. They have opened the junction of a small rich vein that crosses the main vein at that point. The lessees on the Robinson shaft have taken out forty tons of pay rock from the Fitch & Robinson vein in stoping above the 80-foot level, where 1 foot of ore assays four ounces. Lessees Rogers & Mullins, operating in the old shaft this week made a shipment of \$40 ore from the 200 foot level. Lessee McKinsey, on the south end of the Burns claim, has stopped drifting and is extracting ore from the Shurtloff vein, where he has proved up a shoot for 65 feet.

During the month of January the shipments from the Pharmacolite mine, on Bull hill, Cripple Creek, amounted to 200 tons of ore that averaged \$30 per ton. The

property is being operated by four sets of lessees, all of whom are shipping.

Wilder & Co., operating on the Jerry Johnson, on Ironclad hill, Cripple Creek district, shipped a total of 125 tons of ore during January that averaged \$70 per ton in gold. The ore is principally from the 300 level.

H. M. Booth has taken a lease on a portion of the 500-foot level of the Granite mine on Bull hill, Cripple Creek.

An experimental cyanide plant of ten tons daily capacity will be erected on the property of the Boston & Cripple Creek Co. on the northeast slope of Tenderfoot hill, Cripple Creek district, by W. Kirk of Denver.

The Mohawk Belle, on Raven hill, Cripple Creek, has been bonded and leased to Denver men, with R. M. Leshar as superintendent. A lease has been granted on the southern 450 feet of the War Eagle claim on Bull hill to the Gold Cord Co. They are putting in machinery. Work will begin in the 80-foot shaft. The Blue Flag Co., operating the Blue Flag claim on Raven hill, have begun upraising preparatory to enlarging the shaft.

Grant et al., operating the Currency group between Beacon and Guyot hills, Cripple Creek district, have struck ore at a depth of 85 feet, showing 18 inches width.

A steam plant is being installed on the Henry Adney claim on Beacon hill by lessees M. V. Burk et al. They intend to cut the extension of the C. K. & N. vein.

Wyncoop et al., on the Little Besse claim on Beacon hill, have their shaft down 225 feet and will continue to 400 feet, at which depth the lessees expect to crosscut for the El Paso vein and ore shoot.

Four new leases were granted last week on the Trail claim on Battle mountain, Cripple Creek district, belonging to the United Mines Co., to L. W. Rope, P. Wilson and N. Edwards, who secured two blocks adjoining.

Manager J. K. Bruner of the Sand Burr G. M. & M. Co. of Kansas City, owning 140 acres of patented ground at the junction of Oil and Four Mile creeks, north of Gillett, says they are driving a tunnel to cut a mineralized dike opened at the surface, and are in 1195 feet. The ore is of low milling grade and will be cyanided. They expect to cut the vein at 1600 feet. It is planned to build a mill on Four Mile creek, which would furnish the power. The company has a steam power plant installed and is generating its own electricity, using an electric drill in the headings.

The Federal Mines Co. has bought the extension of the Blizzard claim, and also the Saturn, of the Gold Dirt district. The company will cut the extension of the Gomez, Lexington, Blizzard and the Iron Crown vein.

L. W. Terrell & Co. have taken a lease on the Kittle Wells on Tenderfoot hill, Cripple Creek district, and will install a cyanide plant.

The daily output of the Portland mine at Cripple Creek is 250 tons. With the exception of a little high grade it is all treated at the company's mill at Colorado City.

The Sitting Bull of the Keystone Co., near Cripple Creek, is being worked under lease to Kinsle & Co. There is a shaft 350 feet deep on the property.

F. Johnson is putting in cyanide tanks to handle the tailings of the Gillett mill. He says the material will average \$7 per ton.

Sinking is resumed in the three-compartment shaft of the Delmonico at Cripple Creek, on Bull hill, owned by the Union Co. and operated by leasers. They are down 200 feet and will go to the 500-foot point. Ore shipments continue.

The lessees operating the Beacon hill ground of the Old Gold mine, Cripple Creek, are down 200 feet.

C. Perkins, operating on the Compromise mine, Bull hill, Cripple Creek, at a depth of 35 feet struck two veins that cut through the blanket vein, from which ore has been taken, both from that property and the Deadwood, adjoining. The shoot occurs at the junction with the blanket vein.

Sullivan & Jamieson, leasing on the Bison claim of the Free Coinage Co., Cripple Creek, have opened an ore shoot at a depth of 25 feet that is 2½ feet wide and averages \$50 per ton.

The St. Louis M. Co., operating 3 miles south of Cripple Creek, has found an ore body in the shaft at a depth of 200 feet, says Manager P. Lahey.

The Economic mill at Cripple Creek completed its annual cleanup last week and has resumed regular treatment. The mill is handling 150 tons a day, the bulk of which comes from the mines of the Woods Investment Co. Aside from the output of the War Eagle mine little custom ore is treated.

The Taylor & Brunton sampler at Cripple Creek reports more ore in sight

than for many months. This plant is handling on an average 600 tons of ore every twenty-four hours. The value of the ore handled by this plant the last three months has shown an average value of \$41.30 per ton.

L. W. Tirrel & Co. have taken a lease on the Kilty Wells on Carbonate hill, near Gillett. They have a large body of low-grade oxidized ore and will put in a cyanide plant.

G. Hummer, operating through the Sweet shaft of the Gold Bond Co., on Gold hill, Cripple Creek district, is shipping 100 tons of ore per month that averages \$4 per ton gold. The ore is being broken in the first and second levels from a 2-foot shoot.

The El Paso Con. Co. have begun driving on the drainage tunnel from the south drift at the depth of 600 feet in the old shaft with three shifts. The company is driving from four headings in the tunnel. The shaft sunk to 50 feet is finished and driving started both ways from the bottom. In the El Paso a bulkhead has been placed north of the new working shaft, so that pumping will not be necessary to handle water from the drive being made south to connect with the drift below. The deeper shaft is down 225 feet.

IDAHO.

BLAINE COUNTY.

W. G. Page, manager Croesus mine, in the Wood River district, near Halley, has twenty men at work and will sink another shaft and put up a hoisting plant.

CUSTER COUNTY.

A body of ore has been struck in the Albert tunnel on the White Knob Copper Co.'s mine at Mackay, giving assays of 15% in copper, says Superintendent W. H. Cox. The smelter will be blown in in the spring. The electric road connecting the mine and smelter is at present blocked with snow.

SHOSHONE COUNTY.

The Powhatan M. Co., operating a silver-lead property on Big creek, east of Wardner, has decided to sink a shaft on the vein. At present men are drifting on the leads along the hanging wall from the lower crosscut tunnel and a crosscut exposed 16 feet of concentrating ore.

A 10-stamp mill will be installed at the Ozark group of mines, near Pierce City. The Ozark and Red Cloud groups, 3 miles northeast of Pierce City, are under bond to L. H. Prather and C. S. Jennings of Spokane, Wash., with J. J. Wieland, J. T. Penn and Eastern men. A 3-mile ditch will be built.

E. C. Young, secretary of the Silver Cliff copper mines on Stevens peak, near Wallace, says several of the companies in that district will jointly buy a diamond drill outfit to prospect their properties.

MICHIGAN.

HOUGHTON COUNTY.

The Osceola mine, near Houghton, has fifteen drills in operation from No. 5 shaft. The Kearsarge branch is running full time.

Sinking in the exploration shaft on the Abmeek, between the North Kearsarge and Mohawk mines, near Houghton, has been suspended temporarily at a depth of 100 feet. Explorations will continue from the bottom of the shaft with jumper drills. The Abmeek is controlled by the Bigelow Syndicate, and this work is being done to locate the Kearsarge amygdaloid.

The Mass mine, near Houghton, is opened on the Evergreen and Butler lodes, and the Adventure mine adjoining is opened on the Knowlton and Merchants' lode. The production of the Mass mine for the last two weeks of January was: Average of rock stamped per day, 462 5 tons; average mineral obtained, 6 9 tons; average per cent, 1.483. The ore also contains silver.

Shipments of refined copper from the Lake Superior district average over 300 tons daily. All the smelters in the district are handling an increased tonnage and none of the mines are accumulating stocks of refined copper. The activity in the smelting industry and the volume of shipments by rail indicate a good demand for copper.

All the railroads entering the Lake Superior copper country have entered into a joint tariff of 35 cents per hundred on copper consigned to Milwaukee or Chicago, a reduction of 15% to 20% from the former rate, and will tend to increase rail shipments.

The third head of the Champlon mill, Houghton, is in operation and the fourth head of the Baltic is released, the Baltic mill running full capacity on Baltic rock.

The eighth furnace was placed in commission at the Calumet & Hecla smelter the first of the month.

The Miswabik Development Association has been organized at Lake Linden to develop 600 acres of land 1½ miles from the

Mohawk. The property is said to carry the same lode as the Mohawk. The officers are C. Smith, J. Bosch and A. Guck.

At the Champlon mill of the Copper Range Con. Co., near Houghton, two heads are being run tandem, the low pressure head being compounded with the adjacent high pressure head. This is said to be the first experiment of the kind tried at the lake mines.

A 1400 H. P. engine has been set up by the Calumet & Hecla, at Houghton, to drive the generator which will furnish electric power for the new stamp mill. The motor for driving the 60-foot sand wheel is of 700 H. P.

MONTANA.

BEAVERHEAD COUNTY.

The Tombstone M. Co., which recently bought a group of claims in the Vipond district, near Dillon, will put up a 10-stamp mill.

G. Knapp and M. Shaffer are leasing on the Midnight mine, near Argenta. The mine has a shaft 300 feet deep and in the workings the leasers have struck two bodies of gold ore. In one the ore shoot is 18 inches wide and the other 2 feet, and they are taking out twenty sacks a day.

FLATHEAD COUNTY.

A controlling interest in the Flathead-Rambler M. & M. Co., owning mines on Grouse mountain, 8 miles south of Troy, has been sold to Grand Rapids, Mich., men. C. W. Taylor is manager and J. Tholke superintendent. Manager Taylor says hoisting machinery and a concentrator will be installed. The ore carries lead, silver and gold values. There has been 1000 feet of development in tunnels and shafts.

GRANITE COUNTY.

C. J. Smith, president the Montana G. M. Co. mines, 12 miles from Flint, shipped last week a retort of gold weighing 100 ounces, the result of a six days' run with a small Huntington mill at the Sunday mine. The company has taken up its bond on the Sunday claim for \$20,000. It is the intention of the Montana G. M. Co. to increase its ore crushing capacity.

MEAGHER COUNTY.

At the Copperopolis mine at Copperopolis, near White Sulphur Springs, Superintendent W. W. McDowell has pulled the pumps and abandoned the mine, acting on orders from the company.

MISSOULA COUNTY.

The Pennmont G. M. Co. has incorporated at Missoula, C. H. and F. C. Van Slorch, E. A. Clark of Scranton, Pa., and T. S. Letterman, L. J. Knapp of Missoula, to operate placer mines near Lolo and four quartz claims near Nine Mile.

The Oro-Monarch G. M. Co., operating near Deborgia, propose to install a 100-stamp mill in the spring, says Manager Wing.

PARK COUNTY.

D. L. Wing says he will work the placers of Emigrant gulch, near Chico, with steam shovels and dredgers.

NEVADA.

ESMERALDA COUNTY.

W. Grozinger, owning coal lands 19 miles southeast of Candelaria, has let a contract to sink a shaft 200 feet below the lowest workings.

HUMBOLDT COUNTY.

J. A. Lathrop of Boston, Mass., reports having an option on the Rye Patch mine, near Lovelock.

LINCOLN COUNTY.

(Special Correspondence)—The Keystone mine, Yellow Pine district, was in the early nineties a producer, but the ore body was lost and the property supposed to have been worked out. In May, 1901, C. Anderson examined the property and recommended work which resulted in the discovery of a new ore shoot. Sixty thousand dollars was produced during the latter half of 1902 with one 5-foot Huntington mill. A new hoist has been installed and a new shaft is being sunk, now completed to the 200-foot level. A large ore bin has been built at the mine and the mill, which has been shut down since December 15, owing to necessary delay in using the old hoist while the new one was being put in place, will be started the latter part of February.

Sandy, Feb. 5.

G. E. Oils has bought the Little Brown Jug mine, near Searchlight. This claim parallels the Cyrus Noble on the south.

At the Mendha, near Ploche, Superintendent T. J. Osborne is opening up the ledge, which averages \$30 in gold.

LYON COUNTY.

The Douglas M. & S. Co. is incorporated

to operate the Douglas group of mines, near Yerington. A. B. W. Hodges of San Francisco, Cal., is manager. Development machinery will be installed.

NYE COUNTY.

The Tonopah M. Co. at Butler has its Siebert shaft down 600 feet. The drift on the 300 level, connecting the Siebert with the Desert Queen, is completed. The Queen shaft has cut through 24 feet of ore running \$40 per ton. A station has been cut at the 614 foot point. On the east 500 level of the Mizpah ledge the ore body is 12 feet wide, value \$80 per ton. A winze has been started on the east 300 level, which is opening up 6 feet of \$80 ore. In the east and west drifts at the 340-foot level of the Valley View the ledge is 6 feet wide.

The New York-Tonopah M. Co. at Butler have resumed sinking from the 500-foot point and will go to 1000 feet.

The power question at Butler is to be settled by the bringing in of 6000 H. P. from Owens river by electric transmission—a distance of 80 miles from Tonopah. There are forty shafts being sunk in and around Butler.

At the Montana-Tonopah, near Butler, the high-grade ore in the bottom of the shaft has widened to 5 feet on the north side. The north drift at the 400 level is in pay ore. Sinking continues at the rate of 2 feet per day. The first carload of ore was shipped this week.

At Stone Cabin, near Butler, they are drifting and crosscutting on the 300 foot level. Sinking will be resumed. The two-compartment shaft at the Rescue is down 25 feet. Last week several stringers of ore were cut in the shaft of the Midway, down 225 feet.

At the Halifax group, owned by Kelth & Kearns, the hoist is in operation.

The Indiana-Tonopah Co. is sinking a two-compartment shaft on their Owl claim, near Butler. The group consists of sixteen claims.

The main shaft on the Rescue Co.'s mine, near Butler, is down 100 feet and in porphyry. Several quartz stringers in manganese gouge and carrying values have been cut.

The hoist at the shaft of the West End mine, near Butler, is in position and sinking resumed at the 220-foot point, and will go to 1000 feet deep.

The shaft of the Tonopah & Great Western M. Co. at Butler is down 135 feet. Machinery will be put in and further development begun.

STOREY COUNTY.

At Virginia City Superintendent J. R. Ryan says that at the Con. California & Virginia the total extraction of ore for the week ending Feb. 7 was 163 cars, assaying on a basis of gold value \$14.20. At the best & Belcher, at a point in the south drift 100 feet south of the raise, a west crosscut was started and extended 20 feet through porphyry.

NEW MEXICO.

SIERRA COUNTY.

J. B. Taylor has recently completed a contract of crosscut work on the Emporia mine at Grafton. B. S. Phillips, having an option on the property, will put up a mill.

T. Scales has men at work driving a tunnel to cut the Confidence vein in the Cuchillos.

TAOS COUNTY.

L. Rogers, of Waco, Tex., and H. J. Luce, of Red River, have taken up their bond and lease on the Jayhawk group of mining claims at Red River. This property consists of three patented and two unpatented claims. The Jayhawk has a 100 foot tunnel, 100 feet of crosscut, one shaft 45 feet and another 50 feet deep. The lead is 27 feet wide and gives mill returns of \$12 per ton in gold. The National has a 150 foot tunnel with a 7-foot lead. The Palo Alto has a 60-foot tunnel, and the Buena Vista a 40 foot shaft sunk on the lead which runs \$7 per ton. The Jayhawk G. M. Co. has, under the new management, bought the June Bug mill, 4 miles from the Jayhawk mine.

OREGON.

BAKER COUNTY.

A body of milling ore has been opened on the Midway group, recently bought by the Midway Con. G. M. Co., near Sumpter. The ore is in a blind lead, which was cut while drifting on the Midway or Anululu vein. The crosscut shows the ore body 22 feet wide, assaying \$6 per ton, says Manager Hendryx.

The Listen Lake Co. has a quantity of copper ore on the dumps of its Iron Dike claim, near Sumpter, ready for shipment, says Superintendent F. O. Bucknum, and as soon as the smelter is ready to receive ore they will ship. The Iron Dike shaft, at a depth of 30 feet, shows ore assaying 10% copper and \$8 gold. Recently the

company bought the McNamee gulch placers, five claims, and 300 inches of water for power. The placer work will be a side issue.

Operations will be resumed in the E & E mine, near Bourne. A contract has been let for driving a 450-foot drainage tunnel. Shafts and tunnels will be retimbered, and pumps, hoisting and sinking machinery put in.

F. D. Smith, manager of the Snow creek mines in the Greenhorns, near Sumpter, says the crosscut tunnel is in 650 feet. An upraise has been made, connecting with a new shaft. The face of the tunnel is 225 feet in depth from the surface.

The Constellation M. Co., which owns a group of mines at Cable Cove, 14 miles north of Sumpter, has reorganized as the Constellation Con. M. Co. J. Higgins of Cambridge, Md., is manager. It is intended to sink on the ore shoot developed and block out reserves before the erection of reduction works. The ores are a concentrating proposition, assaying \$15 in gold.

A cave occurred at the Columbia mine on the 5th inst. which will close down the mine for sixty days. As the morning shift was changing, the cage with the men had reached the top of the shaft when the main shaft caved for 200 feet from the collar down.

DOUGLAS COUNTY.

The Continental G. M. Co. has incorporated to develop and operate the Continental mine in the South Myrtle district, near Myrtle creek.

GRANT COUNTY.

Work will be resumed on the Climax group, 3 miles north of Granite, owned by the Eastern Oregon G. M. Co. of Spokane, Wash. Superintendent W. Wade of Granite will put in air pipes and machinery required to ventilate the crosscut tunnel, now in 300 feet and which will be driven 300 feet farther to strike the main vein.

The Scandia tunnel, on the north slope of Quehec mountain, near Alamo, is in 2160 feet and being driven with hand drills. It is the intention to continue until they cut the veins proven on the surface or run the entire 3000 feet allowed as a tunnel site.

JACKSON COUNTY.

N. Herbert, operating a quartz property near Gold Hill, in Water Gulch district, has opened up a shoot of free gold ore, 18 inches wide.

Hillis Bros. are operating their hydraulic mine in Pleasant Creek district.

The Opp mines, 1 mile from Jacksonville, have been sold to Eastern men, with W. de Warlia as manager, for \$150,000. A 40-stamp mill is to be installed as soon as the mines are opened up. The Rogue River Valley Railroad will run a branch from Jacksonville to the mine.

It is reported that the Bouden mine, near Gold Hill, will resume. S. McClenodon and L. F. Jordan, controlling the mine, have bought the Braden stamp mill and equipment on Rogue river, opposite Gold Hill, for \$10,000.

N. Herbert, who recently bonded the E. Ray mine, near Gold Hill, sank 50 feet in the old shaft and reports a 19-foot vein, 2 feet of which is rich in gold and tellurides.

JOSEPHINE COUNTY.

In the northwestern part of the county the St. Helens & Galice M. Co. are working on Dutch Boys bar, near Galice, gravel that prospects 50 cents to the pan, says Superintendent A. B. Cousin. This company owns and is operating, by hydraulic, 300 acres of placer ground, on the upper part of Galice creek on both forks.

SOUTH DAKOTA.

CUSTER COUNTY.

The White Cloud G. M. Co. has incorporated at Custer; J. A. Collins, J. E. Pitcher and A. Wilcox. The company has twelve claims 4 miles north of Custer, on Laughing Water, southeast of the Gold Fish group.

Superintendent D. Hensault of the Crown mica mine, near Custer, has resumed operations and is getting out mica for shipment.

The Extreme M. & M. Co. has organized to operate the Golden Mortar, Provo and London groups. It is intended to build a plant on the London group, 3 miles from Custer, the process to be either cyanide or chlorination. J. N. Wright of Custer is manager.

The Interstate G. M. & M. Co. has begun development of its mines, adjoining the Roosevelt group of the Grantz Co., near Custer. T. F. McLaughlin is superintendent.

A carload of mica a month is the output of the Black Hills Porcelain, Clay & Marble Co., operating near Custer.

LAWRENCE COUNTY.

At the Tykoon mine, near Deadwood,

the shaft is down 115 feet and a station is being cut at 100 feet. A crosscut to the lode will be driven. G. Bertschy is superintendent.

Work is resumed at the Titanic mine, near Carbonate camp, west of Deadwood. Machinery will be put in at the shaft, consisting of air compressor and pump. The company owns 1000 acres of land and will explore the quartzite measures. The shaft is 280 feet deep and drifting begun in the quartzite.

The Jupiter M. Co. has bought the Gustin mines, in Blacktail gulch, near Deadwood. The company is installing a cyanide annex to the Minerva mill, which they have bought. The capacity will be 125 tons daily. J. W. Douty of Colorado is mine superintendent. The material in this mine is gold-bearing conglomerate.

An air compressor will be put in by the Big Four M. Co. in their shaft on Deadwood gulch, 4 miles above Deadwood. The company is working in the phonolite belt and has opened up a high-grade ore body. A mill will be built in the spring. The company is composed of Hamburg, Iowa, men.

The Cleopatra M. Co., R. B. Hughes superintendent, will put in an air compressor and machine drills at the mine on Squaw creek, near Deadwood.

The Hidden Spanish Co.'s property, near Brownsville, south of Deadwood, is being developed, with E. H. Darrows superintendent.

The Glover G. M. Co. is setting up a steam hoist and pump at the shaft on Nevada gulch, 2 miles east of Terry. The shaft, 370 feet deep, shows ore that assays \$11. From the bottom of the shaft is a crosscut in 10 feet. It is the intention to continue the shaft and at the 500-foot level drive another crosscut.

The cyanide plant of the Horseshoe M. Co. has a capacity of 1000 tons daily. Ore will be delivered from the mines by aerial rope tramway.

The reduction plant of the Hidden Fortune G. M. Co., 3 miles below Deadwood, is completed. It is arranged for amalgamation and cyaniding. The stamps weigh 1050 pounds each and the plant has a capacity of 300 tons per day. The pneumatic cyanide process will be used. The power is sufficient for a 600-ton daily capacity and it is expected to utilize it to this extent in the spring, says Director H. J. Mayham of Denver, Colo.

PENNINGTON COUNTY.

At the Inca mine, near Mystic, J. Harrington has men drifting on a vein of smelting ore at a depth of 250 feet.

The Fraternity G. M. Co., near Hill City, are sinking the main shaft and are down 100 feet.

The Deer Creek group, 18 miles west of Rapid City, is being developed by J. Keenan and M. Maguire of Rapid City. Nine shafts have been sunk, all of them in ore, some free milling and others of smelting grade, the latter showing values of \$25 a ton. There is one body which is copper pyrite.

R. M. Maloney of Deadwood, of the Maloney Blue Lead C. M. & S. Co., says a copper smelter will be built on their property in this county, near Sheridan.

TENNESSEE.

POLK COUNTY.

Manager R. Adams of the Tennessee Copper Co. at Copper Hill, reports for the fiscal year ended Dec 31, 1902, as follows:

Profits from royalties, merchandise department, tolls and copper production.....	\$303,012
Expenses for bond issue discount, bond issue reserve interest and discount and depreciation.....	71,903
Balance.....	231,109
Add last year's profit.....	55,725
Total profit and loss surplus.....	286,834

The production for the year was 8,103,534 pounds fine copper, in the form of pig and ingot. Sales: Pig copper, 4,349,487 pounds at 10 71 cents net; 866,079 pounds ingot copper at 11 12 cents.

UTAH.

The month of January in the ore and bullion market for Utah closed on settlements aggregating \$2,036,810, the settlements for the corresponding period in 1902 amounting to \$1,138,356, notwithstanding the heavy weather and the reported lower values in some localities. This is exclusive of the tonnages of bullion forwarded by the independent smelters to the Eastern refineries.

BEAVER COUNTY.

(Special Correspondence).—J. M. Callow has been engaged to make the designs for the 1000-ton concentrator and power plant for S. Newhouse's Cactus mine. J. Dedrichs is the contracting engineer. Frisco, Feb. 8.

Manager Farnsworth of the Horn Silver reports the mill at Frisco crushing 140

tons ore daily, with usual tonnage of copper ore marketed.

P. A. Franklin of the Blackbird M. Co., in Copper gulch, near Frisco, says sinking will be resumed in the triple-compartment shaft, now down 280 feet.

The Utah Southern Co., in Beaver Lake district, is running a crosscut for the vein at a depth of 122 feet and expects to cut it in 15 feet more, says F. A. Earls, manager. There are fourteen claims in their group.

W. Hurst and P. S. Martin have opened a deposit of fireclay on their group of claims near Shauntie. It will be tested at the smelter.

CARBON COUNTY.

Superintendent O. H. Bossert of the Raven M. Co., near Price, has sixty men at work (forty being miners), and is shipping 175 tons a month of elaterite, extensively used in the manufacture of electrical insulating apparatus, and also being experimented with as a substitute for hard rubber.

GRAND COUNTY.

W. R. Wheat, superintendent the Grouse Mountain M. Co., near Basin, has begun operations.

The Tornado M. Co., recently organized in Salt Lake, Manager W. S. Larsen, will begin operations on the Tornado at Basin March 1st. The Tornado is on Gold hill, east of the Iowa. A mill will be built. The Iowa tunnel is in 130 feet, with a few feet more to go to cut the vein in the Gold hill contact. A tunnel is being started on the Gold Hill group, adjoining the Iowa on the west, by W. J. Gardner & Co., of Cripple Creek, Colo., owning four claims in the south gold belt.

JUAB COUNTY.

The Dugway M. Co. has been incorporated, A. M., J. M. and E. M. Cannon, M. C. Chamberlain, G. J. Taylor, L. M. Cannon directors. The company has a group of claims in Dugway mining district in the Deep Creek, near Fish Springs.

The Victor and Boss Tweed companies in the Tintic district, near Eureka, will consolidate as the Victor Con. M. Co. Work has resumed through the Victor shaft, with J. Treloar as superintendent. G. Adams, president and manager of the Northwest M. Co., near Eureka, has arranged for a consolidation of the interests of his company with the Dagmar. The working shaft has been sunk 175 feet on the ledge. The company has a hoist with a capacity for sinking to 1000 feet.

Manager Joseph of the Carls M. Co., at Tintic, says lessees have uncovered 6 feet of ore, showing 10% copper, \$2 gold and forty ounces silver per ton. The find is in the Spy and in a faulted channel, which was recovered after driving 30 feet through a stratum of limestone. The company has started a drift to cut the same channel 100 feet below the lessees.

SALT LAKE COUNTY.

The Utah Con. smelter at Bingham forwarded 481,200 pounds of bullion to the East for the week ending Jan. 31. The smelter of the United States M. Co. sent 241,201 pounds, three furnaces being operated. The Bingham Con. did not forward any bullion, although the plant continued to treat 500 tons of rock daily.

J. S. Grow says at the Glenwood Co.'s mine in Polson's canyon, on the north side of Little Cottonwood, near Bingham, the tunnel is in 85 feet on the vein, which is 4 feet between walls. At this point a shoot has been found on the hanging wall which shows 15% copper, nine ounces silver and \$2 gold per ton.

The Mascot tunnel being driven into the Dalton & Lark group at Bingham has passed the 5300-foot station, and next month will tap the Brooklyn ledge at 6000 feet from the portal. From this station they will drift on the Brooklyn. The tunnel will continue across the country to the Lark vein, which will be cut at 7000 feet, and then to the Lead mine ledge at 7600 feet from the mouth of the tunnel.

SUMMIT COUNTY.

Assistant Manager E. Bamberger, of the Daly-West at Park City, says the damage to the Quincy shaft by the recent snowslide is not so great as was at first expected. It will cost \$2000 to put the shaft-house again in repair. The greatest damage will be in shutting off part of the supply of high-grade ore for a time. The output of the Daly-West for January was 8000 tons, valued at \$35 per ton.

Manager Lawrence says the main incline on the Scottish Chief mine, near Park City, has broken into the main ore body.

Manager H. C. Brownlee of the St. Louis-Ontario of Park City says he will put in a hoist to further develop their lower levels.

L. A. Jeffs, superintendent the Wolverine mine, near Park City, says the main tunnel is in 1220 feet with crosscutting. Drifting is in progress, and 427 feet were made last month with two machines.

WASHINGTON COUNTY.

Manager G. Snyder, the Utah & Eastern M. Co., near St. George, has thirty men at work, and the smelter will be blown in on February 25th. An ore body carrying 15% copper has been opened in the shaft and another in a crosscut.

WASHINGTON.

FERRY COUNTY.

J. King of Keller says of the mines at that camp: The Gold Chord, on the east side of the San Poll river, has twelve men at work crosscutting the 325 and the 150-foot levels, and blocking out ore for shipping and for the concentrator which will be put up by the company in the spring. Adjoining the Gold Chord on the west are the Caledonia and the Yellow Jacket. On the Summit the Summit M. & M. Co. has resumed sinking and have begun drifts and crosscuts at the 100 foot level. The shaft follows a ledge 4 feet in width between a schist, hanging and quartzite foot wall. The ore assays \$15 in gold, silver and copper. South of the Summit, at the Silver Hill lode of the Silver Hill M. & M. Co., they are down 80 feet and drifting. On the Malachite, of a group owned by the Lorraine M. & M. Co., a tunnel is being driven to tap the vein at a depth of 260 feet. On the west side of the San Poll, at the Manila, the owners are crosscutting at a depth of 240 feet. The owners of the Iconoclast have bought adjoining property and are putting up buildings.

The California mine, near Republic, shipped three carloads of ore last week to the smelter at Nelson, B. C. Twenty men are employed in the mine and the shaft is being retimbered preparatory to sinking below the 500-foot level. Superintendent Delbridge says a larger hoist, an air compressor and power drills will be put in.

C. Thels has been given an option on the Lone Pine-Surprise mine, in San Poll gulch, north of Republic, for \$150,000. Thels will put in machinery and develop the property.

OKANOGAN COUNTY.

The prospect of railroad transportation by the extension of the Great Northern branch from Curlew through Bolster and to the Okanogan has caused a renewal of mining operations around Bolster. The Lookout property, 1/2 mile southwest of Bolster, under bond to Tacoma men, is being worked by two shifts. Smelting ore is being opened up and assays show values in gold. H. Baldwin, who has a bond on the Grant claims, is working two shifts exploiting that copper property. The Blaine group is being worked by two shifts, says Manager Blaine. Manager Smalley of the Oregon has let a contract for sinking 40 feet deeper in the main shaft.

Work is resumed on the Security group of claims, on the west slope of Palmer mountain, near Loomis, and the tunnel is being driven ahead.

SKAMANIA COUNTY.

The Dixie Queen M. Co. have bought sixteen mining claims in the St. Helena district, near Stevenson. Four of the claims are in the Mountain King group, on which are 75 feet of tunnel, showing a vein 20 feet wide carrying copper sulphides, with small values in gold and silver. Seven of the claims are in the Star King copper group and three in the Star Queen group, on a vein of galena running 20% in lead, with silver values.

WHATCOM COUNTY.

(Special Correspondence).—The Henrietta group is an extension of the Great Excelsior. Nature has done the development work. The ledges, exposed by the cutting through of Wells creek and the Nooksack river, stand several hundred feet above the ground and from 50 to 300 feet wide. Men have been working on the Henrietta preparatory to the erection of a mill. Many assays have shown \$9 50, \$12 and \$16. The Bellingham Bay & British Columbia Railroad will run close to this mine. An extension of the railroad will be completed and running to within 6 miles of this mine about March 1, 1903. Rails are being laid. A further extension will be made over the divide into the Slate creek country. Seattle, Feb. 10.

WYOMING.

ALBANY COUNTY.

The Strong Copper Co. has bought the Strong-Laura group of lode claims in Horse Creek district, northeast of Laramie, for \$1,000,000.

BIG HORN COUNTY.

On Wood river, at Kirwin, near Meeteetse, the Wyoming M. & M. Co., with C. L. Tewksburg manager, have the shaft down 150 feet and showing up a lead of copper ore.

CROOK COUNTY.

The Wyoming-Black Hills R. R. Co.,

recently organ'ed by Twin City men, to develop the coal lands of north-eastern Wyoming, have let a contract for driving a tunnel at the coal mines, west of Sundance.

LARAMIE COUNTY.

It is reported that Omaha men will build a 300-ton smelter on the Platte at Guernsey, says C. A. Guernsey, who is interested in the iron mines in the Sunrise district near there. The Omaha Co. is the owner of the Green Hope copper mine. There are deposits of lime, iron and other minerals used by a smelter near, while coal can be had at Glenrock and coke at New Castle.

FOREIGN.

BRITISH COLUMBIA.

Shipments from Rossland camp for week ending February 7, and for year to date, are as follows:

	Week.	Year.
Le Roi.....	4,369	20,026
Centre Star.....	1,620	8,900
War Eagle.....	990	5,615
Giant.....	50	270
Velvet.....	160	916
Kootenay.....		225
Le Roi No 2.....	260	1,204
Homestake.....		90
Totals.....	7,389	37,246

It is reported G. H. Collins has the Charming claim (Golden Fleece), in the southwestern part of Deadwood camp, under option for \$10,000.

The following figures of output of British Columbia for 1902 are from an official source:

Placer gold.....	\$1,000,000
Lode gold.....	4,600,000
Silver.....	4,600,000 oz.
Copper.....	30,000, 00 lbs.
Lead.....	26,000,000 "
Coal—Crow's Nest.....	441,000 tons.
*Coke—Crow's Nest.....	112,000 "
Coal—Vancouver Island.....	1,290,315 "
*Coke—Vancouver Island.....	15,800 "

*Included in the coal mined.

In upper Pine creek, near Atlin, Loup, Green & Co. are working in ground yielding \$1 to the pan, drifting from a shaft 75 feet back from the creek, and have run in 90 feet. B. Davis & Co., below Loup & Co., are drifting up stream from a shaft 23 feet deep.

The Con. Spruce Creek Placers, Ltd., intend placing a plant on their claims near Atlin this season, says Superintendent Hirschfeld.

J. Lieberman of the Rocky Mountain D. Co., west of the Blood reserve, near New Denver, says they have completed one well, tapping oil at 1020 feet deep. Other wells will be drilled.

Since Porter Bros. began their contract with the Granby mines at Phoenix last summer, stripping from the surface of the Knob Hill and Old Ironsides claims, they have removed 15,000 cubic yards of material. The ore body is exposed for 750x250 feet, not counting the space still in process of stripping on the upper part of the hill.

A strike of copper and silver ore has been made at the Silver King mine, on Toad mountain, near Nelson, by M. S. Davys, lessee. The property is owned by the Hall Mines, Ltd.

The third payment on the Eva mine, Lardeau district, has been made by the Calumet and B. C. G. M., Ltd., amounting to \$10,000, a total to date of \$16,000.

The main shaft on the Iron Horse, Sloan district, is down 300 feet. The closing of the Enterprise has deprived them of power for drills.

The Le Roi No. 2 Co. at Rossland will install an experimental concentration plant and the first tests will be on the low-grade ores of the Josie and No. 1 mines.

The Onward claim, on Kethley creek, near Ashcroft, worked by Velth & Bolland, is producing pay gravel.

C. Chapman has men working deep placer ground on Flindley creek, near Fort Steele. A steam dredger is being put in on Perry creek by the Kootenay-Perry Creek M. Co. H. W. Ross will begin work on the Roaring King gold mine, on Perry creek.

The manager of the Union Jack mine at Ymir says a payshoot of galena has been cut at 165 feet in on the lower tunnel, the ore averaging \$32 a ton. Previous to this strike the vein faulted.

The official returns for 1902 of the Lardeau mining district show: Free miners' certificates, 273; mineral claims recorded, 198; certificates of work, 557, and certificates of improvement, 9.

Superintendent J. L. Parker is sinking the shaft at the North Star mine, near Fort Steele. The St. Eugene mine and concentrator are in operation. The Sullivan mine will resume next month. H. W. Ross is developing the Silver Queen mine on Lost creek, 8 miles from Fort Steele.

MEXICO.

CHIHUAHUA.

The mill of the Adela mine at Santa Barbara is finished, but will not be in operation till March 1, as the aerial tramway of a mile in length is being built, says W. Pett, manager and part owner.

The first payment of \$38,000 gold has been made on the Perros Bravos group of mines, near Parral, by Pittsburg men.

F. McDonald & Co. are working a number of mining properties in Terrazas camp and the Santa Alicia in Victoria camp, 6 miles west of Terrazas. This mine consists of twenty-two pertenencias, from which the ore runs fifty ounces silver.

Dale Bros. & McDonald are working the Guadalupe lead mine at Terrazas. The vein is in porphyry and deposits are found in the horizontal planes. At 65 feet a plane was struck showing ore running 100 ounces silver, 35% lead and some gold.

At Maguarichic, southwest of Miñaca, the Sunset M. Co. will install a lixiviation plant of sixty tons daily capacity.

The Matulana mine at Ocampo, is sold to D. Minahan, of the Belen M. Co., for \$10,000.

Manager N. Lease, of the San Ramon Gold, Ltd., at Ocampo, says operations will be resumed on the San Ramon mine.

DURANGO.

The Mexican National Iron and Steel Co. is building a 100-ton blast furnace and two fire-brick stoves at its plant, a mile north of Durango, at the foot of Iron mountain.

GUANAJUATO.

The Minas de la Casa Real, near Guanajuato, have been sold for \$1,000,000 Mexican money. The sale includes the houses and reduction works in the city of Guanajuato.

SONORA.

(Special Correspondence).—The Creston-Colorado Co. is reported to have disposed of its interests, the control passing Jan. 1, 1903. G. J. McCarty is retained as general manager and J. G. Hardy is assistant general manager.

The 10-inch hole being sunk by the Grand Central Co. near their side line to catch the new ledge in the Creston on its dip is down 800 feet. Work on it is stopped for the present—cause unknown. The Grand Central mine and mill have been shut down for months and the mine dismantled of rails, pumps, etc.

La Colorado, Feb. 8.

A gold strike is reported south of Douglas, Ariz., in the Terres mountains, 40 miles from Cos, terminus of the Nacozari railroad. E. M. Sturges & Co. claim to have taken out several thousand dollars in gold in the last six weeks.

SOUTH AFRICA.

TRANSVAAL.

The mine owners have labor agents in Europe and arrangements are reported made for 6000 Italian laborers. It is also reported that a large number of laborers will be secured in southern Russia.

The total gold output of companies making returns to the Rhodesian Chamber of Mines at Bulawayo for the month of December amounted to 16,210 ounces, an increase of 287 ounces as compared with the previous month, and an increase of 1036 ounces over the corresponding period of 1901. The monthly returns for 1902 have been as follows:

	Ounces.
January.....	15,955
February.....	13,204
March.....	16,891
April.....	17,559
May.....	19,698
June.....	15,842
July.....	15,226
August.....	17,747
September.....	15,164
October.....	16,849
November.....	15,923
December.....	16,210

Total.....194,268

The Chamber of Mines has decided to raise the rate of wages paid to Kaffirs to the scale in force before the war.

Obituary.

CARL BINDER died in Chicago, Ill., on the 4th inst., aged 50 years. He came from Germany in 1884 and attained prominence as a constructing engineer. A widow and two daughters survive him.

F. A. HAYES, superintendent of the Big Five tunnel at Howardsville, San Juan county, Colo., was caught in a snowslide, February 2, while coming from the tunnel and killed. Deceased was 37 years old and leaves a wife and four children.

PERSONAL.

F. C. ROBBINS, E. M., is now located in Los Angeles, Cal.

S. NEWHOUSE of Salt Lake City, Utah, has gone to Europe.

J. C. ROBERTS is superintendent Peabody mine, Grass Valley, Cal.

ED. S. CAMPBELL has returned to Prescott, Ariz., from Chicago.

O. H. BOSSERT is superintendent of the Raven M. Co., near Price, Utah.

J. B. FARISH, a mining engineer of Denver, Colo., is in San Francisco, Cal.

G. M. HAYS president of the Balhinch M. Co., near Eureka, Utah, is in Denver, Colo.

G. S. ANDUS of Globe, Ariz., is consulting engineer of the Gila-Pinal Co., near Globe.

G. MITCHELL, general manager of the Cananea Con. M. Co., is at Cananea, Mexico.

N. LEASE is manager of the San Ramon Gold, Ltd., at Ocampo, Chihuahua, Mexico.

J. W. DOUTY is mine superintendent of the Jupiter M. Co., near Deadwood, South Dakota.

W. H. HANNON of the Indiana-Tonopah mine, at Tonopah, Nev., is in San Francisco, Cal.

C. T. GADSEN, superintendent New Mines Syndicate, Yogo, Mont., has gone to London, Eng.

ALGERNON DEL MAR has gone from Pasadena, Cal., to Pine Grove, Esmeralda county, Nevada.

W. SMITH is assistant superintendent of the Kennedy mine, near Jackson, Amador Co., Cal.

C. T. ROUNER, chief engineer the Electric mine, near Grass Valley, Cal., is in San Francisco, Cal.

W. G. SCOTT, superintendent of the Black Oak mine, Soulsbyville, Cal., is in San Francisco, Cal.

G. W. TYNAN of Independence, Colo., is superintendent of the Hanover mine, Cripple Creek, Colo.

J. GREEN, of Park City, Utah, formerly of the Naylor mine in Utah, is in San Francisco, Cal.

R. D. HUNTER, Western agent Sullivan Machinery Co., has returned from South Africa to Denver, Colo.

C. A. HOLLAND is superintendent of the Altadena mine, near Columbia, Cal., vice J. Filmore, resigned.

J. H. HAMMOND is consulting engineer of the Tonopah M. Co. of Philadelphia, with mines at Butler, Nev.

MANAGER W. C. WYNCOOP of the Liberty mines at Butler, Nev., returned last week from Philadelphia, Pa.

S. LEVY, superintendent the Sampson mine of Bingham, Utah, is in Nevada examining mining properties.

A. I. GOODELL, superintendent of the Sunset smelter near Phoenix, B. C., is in Montreal on company business.

PRESIDENT E. L. WHITE of the Bingham Con. M. Co., Bingham, Utah, has gone to New York on a business trip.

J. FAWCETT, part owner of the Psyche mine, near Sumpter, Or., has returned to Omaha, Neb., from a visit to the mine.

W. J. MCGOFFIN, of Lead, S. Dak., president the United Ruby G. M. & M. Co., is in the East on company business.

J. B. GIRAUD of Prescott, Ariz., is chief engineer of the United Gold & Platinum Co. at Supai, Coconino county, Ariz.

H. H. HELM of Prescott, Ariz., has accepted a position with the Guggenheim Exploration Co. at Santa Barbara, Mexico.

F. D. ADAMS has resigned as superintendent of the Gila-Pinal M. Co., near Globe, Ariz., and has gone to Oakland, Cal.

G. W. LAMOS is putting in machinery for the Mine & Smelter Supply Co. of Denver, Colo., at Grand Encampment, Wyo.

SUPERINTENDENT W. W. WARREN of the Butte-Tonopah mine, near Butler, Nev., is in San Francisco, Cal., on business.

GEO. H. STRONG of the patent firm of Dewey, Strong & Co., has returned to San Francisco, Cal., from Honolulu, Hawaii, U. S. A.

J. DOYLE, manager of the Giant Tonopah M. Co., returned last week to Butler, Nev., from a business trip to San Francisco, Cal.

F. G. STEVENS, a mining engineer of Rossland, B. C., has returned from a two months' visit to Halifax and other Eastern points.

CARL ANDERSON will act as consulting and managing engineer for the Nevada Keystone M. Co., Yellow Pine, Lincoln county, Nevada.

CHAS. F. HENDRIE, treasurer The Hendrie & Bolthoff Mfg. & Supply Co., has returned to Denver, Colo., from an extended European trip.

F. O. CHAMBERLAIN of Bakersfield, Cal., vice-president of the Butte-Tonopah M. Co., near Butler, Nev., will take up his permanent residence at Butler.

E. HAWLEY of New York has been elected a member of the executive committee of the Greene Con. Copper Co., of Cananea, Mex., vice A. Romer, resigned.

L. HARRIS, formerly manager of the Revenue mine, in Montana, is manager of the Sunshine M. Co.'s mines and mill at Sunshine, Utah, vice G. Moore, resigned.

GODFREY DOVETON, metallurgist of the Camp Bird mills, Ouray, Colo., will establish an office in Denver, Colo., about the 20th inst., resigning from the Camp Bird.

G. MOORE has resigned as manager of the Sunshine M. Co.'s mines and mill at Sunshine, Utah, and gone to Milford, Utah, to examine a group of copper properties.

S. F. PARRISH, formerly manager of British Columbia mine, in Summit camp, near Greenwood, B. C., has gone to Rossland, B. C., to take the position of manager of the Le Roi mine at Rossland and the Le Roi Co.'s smelter at Northport, Wash.

Commercial Paragraphs.

J. H. GIBSON has opened offices at 944 Monadnock building, Chicago, Ill., furnishing mine and smelter supplies.

NORMAN A. ROOT, formerly with Henshaw, Bulkley & Co., is now established as an engineer and machinery commission merchant at Room 403, 519 Mission St., San Francisco, Cal.

THE C. O. Bartlett & Snow Co., Cleveland, Ohio, write that they are in receipt of a large order for fertilizing machinery from the West Rand Fertilizer Co., Krugersdorp, Transvaal, South Africa.

THE Stilwell-Bierce & Smith-Valle Co., Dayton, O., write that Geo. W. Ingalls has been appointed direct representative of that company with offices at 11-13 First street, San Francisco, Cal. Associated with Mr. Ingalls, and in charge of the water wheel department, E. G. Dewald will be permanently connected with this office. The company state that they will be prepared to make estimates on water wheel units from 10 to 16,000 H. P. from 6 to 2000 feet head.

THE J. H. Montgomery Machinery Co. of Denver, Colo., report having sold during the past week to the Rex Cobra Mining Co. of Chloride, Ariz., the Keystone Bank of Keystone, S. D., H. S. Merrill of Gold Hill, Colo., and the Golden Banner M. & M. Co. of Custer, S. D., one each of their Common Sense steel whips, with hoisting rope, buckets, cars, etc., and that they also outfitted the Colorado Springs Pressed & Fire Brick Co. with belts, shafting, etc. They report the prospects for next season bright and that they are making figures for several large cyanide and concentrating mills.

MANY of the largest cement manufacturers of the country, appreciating that the Griffin mill gives satisfaction as a cement grinder, are buying large numbers of these mills. Among the new orders booked by the Bradley Pulverizer Co. during the month of January have been the following: Penn Allen Portland Cement Co., Allentown, Pa., entire grinding machinery for their new works; Lehigh Portland Cement Co., grinding machinery for 2000-barrel plant to be erected at Ormrod, Pa.; Quaker Portland Cement Co., grinding machinery for their 4000-barrel plant to be erected at Stockertown, Pa.; also additional mills for the Lehigh Portland Cement Co. at their mill D in Mitchell, Ind., mill A, Ormrod, Pa., mill B, West Copley, Pa.; additional grinding machinery for the Iroquois Portland Cement Co., Caledonia, N. Y., and also for the Wolverine Portland Cement Co., Coldwater, Mich., and the Bronson Portland Cement Co., Bronson, Mich.

Books Received.

Bulletin No. 7, being a general review of mining in British Columbia, has been received. It contains much valuable information regarding the mines of that province. Bulletin No. 9 of the same department treats of the undeveloped regions of the province.

"The Diamond Mines of South Africa," by Gardner F. Williams, is the title of a handsome volume (edition de luxe) containing 681 pages, with several hundred illustrations, many of them of superb design and execution. The book deals with the subject in every phase from which it can be viewed: Historical, technical, practical and scientific. It describes in detail the interesting geological occurrence of the diamonds of South Africa, the means formerly employed to recover them, and the present practice as developed under the direction of the author himself. The mining, milling and washing processes are fully described. The chapters devoted to modern mining methods as applied to these mines are very interesting and instructive. The surface plants, steel head-frames and works are also given the space their importance deserves. Cutting and polishing the diamond is described in all its interesting detail and considerable space is devoted to the social and political life of South Africa. Not the least interesting portion of the book is the description of the late war in South Africa, and its effect on the diamond mining industry. The volume will take its place in the classics of mining literature. Price, \$10; The Macmillan Co., New York and London.

Catalogues Received.

The fourth edition of the Farrell Ore and Rock Crushing Machinery Catalogue, from Earle C. Bacon, Havemeyer building, New York, is replete with illustrated information of the various styles and sizes of such machinery made by that company. It is finely produced and, besides other data, gives many handsome views of large crushing and milling plants.

Catalogue No. 75 from the Jeffrey Manufacturing Co., Columbus, Ohio, is devoted mainly to the Barney Brick Conveyor system, profusely illustrating and describing its manner of operation. The Century belt conveyors, bucket elevators, chains, screens, mixers, water elevators, horse powers, electric storage battery locomotives, excavators, loaders and other labor-saving appliances made by the Jeffrey Manufacturing Co. are also illustrated in their handsome treatise.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

DOUGH CUTTING AND WEIGHING MACHINE.—No. 719,923. Feb. 3, 1903. H. P. West, San Francisco, Cal. This invention relates particularly to that class of machines which are designed for the weighing of plastic materials, such as dough, and the object is to provide a continuously operating machine into which a mass of dough may be fed and which machine will automatically separate the desired quantity from the mass and weigh and deliver the same.

STACKING LUMBER.—No. 719,663. Feb. 3, 1903. F. M. Hazleton, Sierraville, Cal. This invention relates to improvements in stacking lumber, and is especially designed for the care of the "sit kers," so-called, which separate the lumber, and the protecting roof boards. It consists of a series of posts set between each of the lumber stacks and having transverse bars or sections attached at intervals between the top and bottom for the purpose of holding the stacks. These posts also have caps at the top which receive joists across the two ends of the stack, and these joists serve to carry a roof or covering to protect the lumber from sun and weather. The object of this is to provide a means for preserving the roof boards and stickers and holding the latter in place for convenient use.

OIL BURNERS AND FEED MECHANISM THEREFOR.—No. 719,716. Feb. 3, 1903. John W. Anderson, San Francisco, Cal. This invention relates to improvements in hydrocarbon burners for use in boiler furnaces and the like, in which steam and oil or kerosene are coming fed to form the inflammable vapor. Its main object is to provide a burner of simple construction suitable for low grade oils, and which will give an equable distribution of heat in the fire-box without the use of baffle walls. Another object is to effect improvements in the manner of attaching the burner to the furnace door, and in means of connecting the burner with the source of fuel supply, whereby the burner may be withdrawn from the furnace simultaneously with the opening of the door.

BAKE OVEN.—No. 719,551. Feb. 3, 1903. C. P. Dowd and J. H. Coleman, San Francisco, Cal. This invention relates to improvements in bakers' ovens of the type commonly known as "cracker ovens," in which the heated products of combustion are discharged directly into the oven chamber and in

which chamber is a revoluble reel or wheel with pendant trays carrying the articles to be baked. The object of the invention is to adapt these ovens to the use of oil fuel and to secure better means of heat distribution and control than has heretofore been possible. The object is effected by a certain arrangement of flues and dampers, and by using crude oil as fuel we can at all times regulate the fuel feed to the amount of heat necessary in the oven chamber and can distribute the heat therein according to the nature of the articles to be baked.

SKIRT SUPPORTER.—No. 719,555. Feb. 3, 1903. J. H. Griswold, Oakland, Cal. The object of this invention is to provide a simple, artistic, economically constructed holder which can be quickly engaged with or disengaged from the skirt, and which will not tear or otherwise injure the finest fabric. It consists of a skirt holder comprising a tubular handle, a wire passing the end thereof, in which members the folds of a dress are adapted to be engaged, the ends of said wire encased within the handle and having a sliding movement therein whereby said clasp members may have a limited movement to and from each other.

APPARATUS FOR MAKING HOLLOW ARTIFICIAL STONE BLOCKS.—No. 719,555. Feb. 3, 1903. Secondo Ciletti, San Francisco, Cal. This invention relates to improvements in devices for forming hollow blocks, tiles and the like used in building construction. Its object is to provide a mold with a contractible core, which can be readily withdrawn after the block has been cast about it. The invention comprises the combination, with a suitable mold, of a core having its walls pivotally connected by radially disposed links, with a lever extending centrally through the core whereby the walls of the core may be expanded or contracted, according as the links are operated in the act of inserting the core into the mold or withdrawing it therefrom.

OIL BURNER.—No. 719,555. Feb. 3, 1903. J. J. McDonald, of Berkeley, and A. D. McLean, of San Francisco, Cal. This invention has for its object to provide a burner for low-gravity oil and suitable for use, particularly with marine boilers. It consists essentially in the combination of a casing or shell, an oil pipe extending centrally through the casing, a jetting beyond the front end of the casing, an annular steam chamber formed between the casing and said pipe, an annular beveled-edge partition adjustable on said pipe and adapted to form an annular steam passage with the end of the casing, a cap or second casing member supported on the extension of the oil pipe, an annular oil chamber formed between said cap and pipe, and an oil outlet between the adjacent edges of the cap and partitions.

PORTABLE FOOT AND BODY WARMER.—No. 719,638. Feb. 3, 1903. F. Battier, Tillamook, Or. This invention relates to a device which is designed to be carried or worn by individuals under conditions where the natural heat of the blood is not sufficient or in which there is intense exterior cold against which the person should be guarded. It consists in the combination in a portable heating apparatus of a case secured to the person, a heater contained within the case, a plurality of pads applied to the extremities, cuffs or pipes connecting the heater with the pads, return pipes and receivers within the case into which said pads discharge, and through which the circulating medium is returned to the heater, and a valve located between the receiver and heater and mechanism, by which it is intermittently opened or closed.

WALL OR CHIMNEY CONSTRUCTION.—No. 719,679. Feb. 3, 1903. J. F. Lyman, San Francisco, Cal. This invention relates to improvements in the construction of walls, chimneys, and like structures. It consists in a means for building such structures, as concrete with one or more hollow tubular openings formed within the structure and extending from the bottom to the top. In the construction of chimneys having one or more flues, or of walls for buildings in which such passages are to be made, either to be used as chimneys or for the convenient laying of gas and water pipes, a electric and other conductors, wires, or for heat passages for furnaces, it is desirable to form such walls by building them up continuously of concrete and simultaneously forming the open passages from bottom to top. In order to build the walls and continuously extend these passages forms or molds are employed, between which the concrete is tamped and within the space between the walls are other forms, which are placed as to form the continuous openings between the walls.

New Patents.

DEWEY, STRONG & CO'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR THE WEEK ENDING FEBRUARY 3, 1903.

719,716.—OIL BURNER—J. W. Anderson, S. F.
719,632.—RAILWAY SIGNAL—C. P. Bass, Portland, Or.
719,638.—FOOT AND BODY WARMER—F. Battier-Tillamook, Or.
719,563.—PURGLAR ALARM—I. S. Bunker, Free water, Or.
719,738.—LOADING FISH TRAP—A. C. Burdick, Seattle, Wash.
719,746.—FLUID CLUTCH—B. B. Chandler, Jr., Nevada City, Cal.
719,751.—SPIRAL ELEVATOR—D. E. Condon, S. F.
719,567.—EXCAVATOR—J. J. Conlin, S. F.
719,651.—BAKE OVEN—Dowd & Coleman, S. F.
719,652.—SMOKE FLUE—D. Elstein, S. F.
719,655.—HOLLOW STONE BLOCKS—S. Giletti, S. F.
719,582.—COLD SEPARATOR—J. H. Gray, S. F.
719,656.—SKIRT SUPPORTER—J. H. Griswold, Oakland, Cal.
719,663.—STACKING LUMBER—F. M. Hazleton, Sierraville, Cal.
719,810.—FRUIT RECEPTACLE—J. J. Jones, Los Angeles, Cal.
719,675.—MASSAGE MACHINE—F. King, S. F.
719,477.—TRAMWAY CARRIAGE—F. H. Lamb, Hoquiam, Wash.
719,478.—CAHLEWAY—F. H. Lamb, Hoquiam, Wash.
719,679.—WALL CONSTRUCTION—J. F. Lyman, San Francisco, Cal.
719,688.—OIL BURNER—McDonald & McLean, S. F.
719,488.—PROCESS—Geo. Mitchell, Naco, Ariz.
719,905.—SEEDER—J. Thooljian, Del Rey, Cal.
719,923.—DOUGH MANIPULATOR—H. P. P. West, S. F.
719,930.—SALES BOOK—H. H. Winslow, Portland, Or.

Latest Market Reports.

SAN FRANCISCO, Feb. 13, 1903.

METALS.

SILVER.—Per oz., Troy: London, 21s 15d (standard ounce, 925 fine); New York, bar silver, 47½¢, refined (1000 fine); San Francisco, 47½¢; Mexican dollars, 38 @39¢ San Francisco, 37½¢ New York.

The above quotations show a small raise in price over a week ago, but are of no particular importance.

COPPER.—New York: Standard, \$12.50; Lake, 1 to 3 casks, \$12.75; carload lots, \$12.00; Electrolytic, 1 to 3 casks, \$12.85; carload lots, \$12.50; Casting, 1 to 3 casks, \$12.75; carload lots, \$12.50. San Francisco: \$14.00. Mill copper plates, \$17.00; bars, 18@24¢. London: 257 5s spot per ton.

The enormous consumption of copper in 1902 is indisputable, and it is recognized that the demands for 1903 cannot be other than great. This fact alone might furnish a specific explanation for a large measure of the sanguine tone regarding the future of the market, although other potent forces are tending in the direction of securing more normal conditions. Production is large and on the increase at some sources; but, notwithstanding all the growth in output during the past twenty years, the available free copper left over on January 1, 1903, amounted to a comparatively small percentage of the total production for the two decades ended with 1902. United States copper production from 1883 to 1902, inclusive, amounted in the aggregate to 7,215,944,524 pounds; and taking the very highest estimate of stocks existing at the beginning of this year, among all the published statistics, the quantity of copper available in this country was less than 4½% of the above-named production, including imports also during the period named.

LEAD.—New York, \$4.12½; Salt Lake City, \$3.50; St. Louis, \$4.00; San Francisco \$4.50, carload lots, 4½¢ 1000 to 4000 lbs.; pipe 5½, sheet 6, bar 5½¢; pig, \$4.75. London: £11 8s 9d per long ton = 2.47¢ per lb.

SPELTER.—New York, \$5.05; St. Louis, \$4.60; London, £20 7s 6d per ton; San Francisco, ton lots, 6½¢; 100-lb lots, 7¢.

ANTIMONY.—New York, Cookson's, 9½¢; Hallett's, 8½¢; San Francisco, 100-lb. lots, 10¢; 300 to 500 lbs., 11¢; 100-lb. lots, 13@15¢.

TIN.—New York, pig, \$29 30@29 35; San Francisco, ton lots, 31¢; 500 lbs., 31¢; 200 lbs., 31¢; less 3¢; bar tin, \$1.35 @37½¢. London, £132 7s 6d spot.

PLATINUM.—San Francisco, crude, \$18.00 per oz.; New York, ingot, \$19.00 per Troy oz. Platinum ware, 75@80¢ per gram.

QUICKSILVER.—New York, \$45.50@46.00; large lots, London, £8 15s; San Francisco, local, \$45.50 per flask of 7½ lbs.; Denver, \$49.50. Export, \$43.50.

BABBITT METAL.—San Francisco, No. 1, 10¢; No. 2, 7¢; No. 3, 6½¢; extra, 17½¢; genuine, 35¢; Eclipse, 37½¢.

ALUMINUM.—New York, No. 1, 99¢ pure ingots, 35¢; No. 2, 90¢, 30¢ to 34¢.

SOLDER.—Half-and-half, 100-lb. lots, 20¢; San Francisco, Plumbers', 100-lb. lots, 16 65¢.

NICKEL.—New York, 50@60¢ per lb.; ton lots, 45@48¢.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$21.85; gray forge, \$20.50; San Francisco, bar, 3¢ per lb., 3½¢ in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$30.00; open hearth billets, \$31.00; San Francisco, bar, 7¢ to 12¢ per lb.

Special rates for carload lots.

GENERAL SUPPLIES.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15¢; less than one ton, 17¢. No. 1*, 60%, carload lots, 13¢; less than one ton, 15¢. No. 1** 50%, carload lots, 11¢; less than one ton, 13¢. No. 2, 40%, carload lots, 10¢; less than one ton, 12¢. No. 2* 35%, carload lots, 9¢; less than one ton, 11¢. No. 2** 30% carload lots, 9¢; less than one ton, 11¢. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2 per keg.

CAPS.—3x, \$5.50 per 1000; 4x, \$6.50; 5x, \$8; Lion, \$9, in lots not less than 1000.

FUSE.—Triple tape, \$3.60 per 1000 feet; double tape, \$3.00; single tape, \$2.65; Hemp, \$2.10; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10½¢ per set; 14 oz., 40s., 9½¢.

CEMENT.—Germania, \$2.50 @ 2.75; Hewmore, \$2.90; Trowell, \$2.90; Portland, \$2.50 @ 2.75 per bbl.

LIME.—Santa Cruz, \$2.25; Roche Harbor, \$2.25 per bbl.

OILS.—Linedseed, boiled, bbl., 56¢; cs., 61¢; raw, bbl., 54¢; cs., 59¢; Lucid oil, boiled, bbl., 50¢; cs., 55¢; raw, bbl., 48¢; cs., 53¢. Kerosene—Pearl, per gal., 22½¢; Astral, 22½¢; Star, 22½¢; Extra Star, 25½¢; Eocene, 24¢; Elaine, 27½¢; Water White, in bulk, 16¢; Mineral Seal, iron bbls., 18½¢; wooden bbls., 21¢; cs., 24¢; Mineral Spermin, cs., 26½¢; Deodorized Stove Gasoline, bulk, 17¢; do., cs., 23½¢; 86° Gasoline, bulk, 21¢; do., cs., 27½¢; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 16¢; do., in cs., 22½¢; do. Lard Oil, E. W. S., bbl., \$1.00; cs., \$1.05; Neats-foot Oil, pure, bbl., 75¢; cs., 80¢; cs., No. 1 bbl., 57¢@60¢; Spermin, crude, 50¢@60¢; Natural White, 65¢; Bleached do., 70¢; Whale Oil, cs., 50¢@55¢.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6¢; less than 500 lbs., per lb., 6½¢; in 25-lb. tin pails, 7¢ per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, 7¢ per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6¢; do. in kegs, 6½¢.

RED LEAD.—500 lbs. and over at one purchase, per lb., 6¢; less than 500 lbs., 6½¢.

LITHARGE.—Pure, in 25-lb. bags, 8 @9¢ per lb.

BONE ASH.—Extra No. 1, 5@6¢ per lb. No. 1, 4@5¢.

BORAX.—Concentrated, 7@9¢ per lb.; powdered, 9@12¢; fused, 25@30¢.

BISMUTH.—Subnitrate, per lb., \$1.60.

BONE ASH.—4¢ per lb.

BORAX.—Crystal, 7¢; calcined, 25¢.

COPPER.—Sulphate, 5@7¢.

MANGANES.—(90% and over) per lb., \$1.25.

MOLYBDENUM.—250. 3 grammes; 1000 grammes—2½ lbs.

CHROMIUM.—(90% and over) per lb., \$1.25.

SODIUM.—Metal, per lb., \$1.25.

MERCURY.—Bichloride, per lb., 90¢.

PHOSPHORUS.—(American) per lb., \$1.00.

SILVER.—Chloride, per oz., 90¢@1.00; nitrate, 55¢.

URANIUM.—Oxide, per lb., \$3.50.

ZINC.—Metallic, chemically pure, per lb., 50¢; dust, per lb., 10¢; sulphate, per lb., 10¢. (These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

Types of Head Frames.

The designing and construction of head frames are always matters of interest to the miner and engineer. Often the situation has an important bearing upon the type of frame selected, though under more favorable economic conditions some other type of frame would have been chosen. This is particularly exemplified in Fig. 3, which illustrates the head frame built at the Moon-Ancor mine, Cripple Creek, Colo. The timber obtained from local sources is inferior in quality and cannot be obtained in long sticks. The cost of Oregon pine being high, owing to railroad transportation, it was determined to build a structure of the timber cut in the neighborhood, and the frame shows clearly what ingenuity in design and mechanical skill can accomplish under difficulties like those mentioned. All of the timbers employed are short and knotty, requiring much splicing and extra bracing, but the frame is sub-

Fig. 1.—Head Frame Congress Mine, Arizona.

stantial and will answer every purpose. In the early history of Leadville millions of dollars worth of ore were hoisted from some of the richest mines in the district by employment of small hoisting plant and "tripod" frames—the simplest possible construction—but they answered the purpose at the shallow mines on Fryer hill. Fig. 4 illustrates a modern head gear in course of construction at the Wolfstone mine, on Carbonate hill, Leadville; and, though possibly from the standpoint of an engineer it does not represent the highest type of engineering skill, it has the merit of the smallest amount of material possible in a frame of its kind, in which respect it is in decided contrast with that at the Moon-Ancor mine of Cripple Creek. Fig. 2 represents a two-post frame at Cripple Creek. It is of simple construction and of a type in much favor in Montana and South Dakota, and more recently in California. A frame of this type can be employed at either a vertical or inclined shaft. Fig. 1 represents a third type of frame. Here, owing to lack of dump, the frame has been built upon a substructure of posts and caps. An unnecessary amount of material and labor has been wasted on this frame, which has little to recommend it beyond the fact that it is substantially built. It is at the Congress mine, Arizona.

Head frames should be constructed as cheaply as possible and of the best material available, but there is a great deal of difference in the design of frames, even in the same district. Some of the types most commonly seen have been adopted because they require less engineering and mechanical skill than others of a better and really simpler

type. In the four-post frames so often seen at least two of the main members of the frame are relatively useless, taking little or none of the resultant strains when hoisting is in progress. These two members are the two posts forming the front of the frame. The construction of the two-post frame fully illustrates this. Another important matter often overlooked is the necessity that the strain, the direction of which is between the upright posts and the hoisting reel, should fall inside the back braces.

Fig. 4.—Four Post Frame, Wolfstone Mine, Leadville, Colo.

THIS is the 2222nd issue of this journal. It looks different from the 1111th issue, and the 3333rd issue will, doubtless, look different from this one. It is interesting to note in the old files the history of mining and metallurgy through the years and the progress therein, an advance in which this journal has so prominent a part. A present thought in connection with the two thousand two hundred and twenty-second issue of this journal is the increase in the number of publications devoted to the allied industries that this journal has represented for nearly forty-three years. Time was when there was but one—the MINING AND SCIENTIFIC PRESS—in the whole country. Then one was established in New York City in 1866, another in Denver, Colo., in 1873, and now there are few mining centers west of the Missouri that have not a mining paper, sometimes two or more, a gratifying fact, showing what prominence the mining industry has assumed with the growth and development of the country; showing, too, that all this growth and development is consequent upon the nation's mineral wealth, and that if it were not for its mineral resources the west half of the United States would be a century behind what it is. Where none but the daring started and none but the strong survived the foundations of the great mining commonwealths were laid in the years when a few scattering stage coaches carried the MINING AND SCIENTIFIC PRESS to isolated mining camps. That is a vanished era replaced by the busy hum of mining industry that has reflex in the pages of the present issue.

EXCESSIVE capitalization of new mining enterprises is not nearly so deplorable as misstatements of fact concerning the extent and real value of ore bodies, and other conditions having a direct bearing on the value of the proposition.

The Valuation of Mines.

When a mining engineer is called upon to examine and report upon a mine he takes upon himself a responsibility which may be far-reaching in its consequences, for upon his report money is likely to be invested or withheld from investment. He should not only make a careful investigation of the resources and condition of the mine, but should state every fact in any way having a bearing upon the cost of operating the property. It is comparatively easy for an experienced engineer to sample a mine, and by this means arrive at the gross value of the various blocks of ore as exposed in the workings, having the estimate on the average value of samples and the amount of ore "in sight," and many reports containing this sort of information neglect to give the cost of operations.

In addition to gross values of ore in sight should be given the cost of extracting the available ore, and of converting it into bullion, but some engineers do not give these figures, though offering no reason for failing to supply them. It is true, in some isolated cases, arbitrary costs may be difficult to arrive at, but ordinarily this is not so, there being sufficient precedent upon which to have approximate estimates, in the cost of operating other properties in the neighborhood.

Undoubtedly some engineers hesitate to give figures of probable cost for fear that those who may subsequently have the management of the property may work on different lines from those suggested in the report, with a consequent difference in cost, which may or may not be complimentary to the engineer making the estimate, but if the report is based upon the actual conditions and costs obtaining at the time the report is made, the engineer need feel no hesitancy in expressing his own conclusions. Some noted records have been made by engineers, who, having rendered a report on mining property, including statement of cost, and being placed in charge of the property, have made the expense account correspond so closely to their previous estimate of cost as to cause much favorable comment on the part of the owners.

Viewed from another standpoint, the person employing the engineer may desire to have the cost of mining and reduction omitted, as without the costs the report makes a favorable showing, owing to the large amount of "ore in sight," but if the cost of mining this ore and reducing it accompany the report, the most favorable statement would prove the property incapable of producing a profit. A noted engineer reported on a gold property some years since, and in his report stated that there were four millions of dollars in sight. Another engineer was sent to verify the report, and did so, but added that it would require five millions to get it out. This case is directly in point, and shows the necessity of a careful engineer making a report so complete that whoever may have occasion to read it may comprehend the situation in all its details, and from a business standpoint be able to judge of the commercial value of the property for themselves.

Timber on Unsurveyed Lands.

Unusual activity in the land department at Washington, D. C., has resulted in the seizure of a large amount of cord wood and mine timbers at Republic, in Washington. This timber has been cut on the unsurveyed lands in the northern part of the Colville reservation. The mining companies did not cut the timber, but as the men who did the cutting are poor and unable to pay for the trespass, the government agents are calling upon the mining companies for a settlement. The same thing has occurred many times in the past elsewhere, and in each case the government has shown a disposition to make the assessment as light as possible, as the fact is recognized that the timber is absolutely essential to the operation of the mines. The usual practice has been to fix a nominal price on the timber cut, as determined by the stumpage, without assessing additional charges as penalties. There is said to be no timber available other than that on the unsurveyed land of the government, and should the authorities deal harshly with the mine owners it would probably result in a suspension of mining operations there. The timber lands of that section of the State cannot be taken up

under any of the laws regarding timber lands, owing to the probability of its proving to be mineral land. In view of the circumstances, a satisfactory adjustment of the difficulty may be anticipated.

The Department of Commerce.

The new Cabinet Department of Commerce has begun its work with Secretary Cortelyou, the latest addition to the President's Cabinet. This journal had hoped that when a new department was created it would have been a Department of Mines, and did some energetic work in that direction, but public opinion east of the Rockies had not crystallized sufficiently, and the necessary recognition of the importance of the nation's greatest basic industry is deferred. However, next to the creation of a Cabinet Department of Mines and Mining, the most favorable governmental act affecting the development of the country's mineral resources is the new Cabinet department that begins its work this week, as it directly aids in the advancement of American manufactures, and thus indirectly in the advancement of the country's developed mineral wealth. In this regard it is to be observed that Secretary Cortelyou, the ninth addition to the President's official assistants, will direct the greatest commercial interests on the globe. His department has jurisdiction over the internal commerce of the country. This aggregated two billion dollars in 1850; three and one-half billions in 1860; six and one-fourth billions in 1870; seven and three-fourths billions in 1880; twelve billions in 1890; eighteen billions in 1900, and this year exceeds twenty billions. That is, it has increased ten-fold in fifty-three years. During the same period the population of the United States increased from twenty-three millions to eighty-two millions. So that while the country's internal commerce has increased ten-fold, the population has not increased four-fold. This is largely due to facilities of transportation, the inventive genius of our people, the richness of the country, and the development of our mineral wealth. In this increase of commerce the miner is a foremost factor. And not only in the production of mineral wealth, but in its manufacture, the mining States show gratifying advance. Take the one State of Colorado, which in 1890 showed a total of manufactures of \$42,480,205, and in 1900 produced a total of manufactures of \$102,830,137. Similarly may be cited the State of California, which in 1890 manufactured to the extent of \$213,403,996, and in 1900, \$302,874,761. Other commonwealths show equal proportionate advance, illustrating that mining and manufacturing go together, and that the ancient and honorable order of miners and metallurgists ever foster and encourage manufactures and the creation of industrial wealth. Hence it is with pleasure miners everywhere note the creation of the new Cabinet department, and with confidence look forward to the day when there shall also be a Department of Mines and Mining.

THE usual amount of State mining laws is before the State Legislatures. In Colorado the principal measure is a proposed eight-hour law for underground workers, which stands good show of being enacted. In California the bill establishing a State mine inspector is probably destined to the same defeat it has had before. Idaho has an eight-hour measure and a bill taxing the net profit of mines, which will apparently become a law. Oregon is trying to get needful appropriation for a State mining bureau. In Montana a bill has been introduced looking to the abatement of the smoke nuisance. The only way in which this may be wholly accomplished is by closing the smelters, and it is to be hoped the bill may not become a law. In Utah a bill has passed the Senate making it a misdemeanor for any mine operator to store in the mine any high explosive more than sufficient to supply the mine for twenty-four hours.

REPRESENTATIVES of the Utah Legislature J. H. Johnson and D. H. Morris are in Phoenix, Arizona, for the purpose of conferring with the Arizona Legislature on annexing that portion of Arizona Territory north of the Grand canyon of the Colorado to the State of Utah. For topographical reasons, if no other, this might be of some benefit, as the territory north of the canyon is practically inaccessible from the south side.

CONCENTRATES.

THE appearance of tin reported in the slags of Leadville blast furnaces may possibly be traced to the tin scrap used as a flux.

THERE is no standard price on manganese ore. The demand locally usually has an important influence on cost. Ore containing but 30% is low grade. Sixty per cent ore in San Francisco, Cal., is worth about \$10 per ton. It is sometimes bought by smelters for flux.

A MILLSITE cannot be patented separately unless it has on it a mill or other works for the reduction of ores, but in such case the millsite must be claimed independent of any lode claim ownership. Proof of the non-mineral character of the land must also be furnished.

METALLURGICAL PROCESSES which work well on a small scale in the laboratory do not always work well on a commercial scale, and experimenters should proceed cautiously, increasing the quantities employed in experiment until there is no doubt of the application of the laboratory process to commercial practice.

WHERE a mining company owns several claims on one hill or emulsion, but these claims are separated by other claims intervening, the owner of a tunnel, the mouth of which is located on the side of the hill, cannot reach the higher claims by driving through the intervening claim in which he has no interest, although he would be greatly benefited by such privilege.

THOSE seeding questions to "Concentrates" which involve possibly conflicting claim boundaries, extralateral rights, or any controversy over claim lines or disputes, can make the case much more comprehensive if they will send with their questions a sketch showing the relative position of claims, outcrop, dip, etc. The answers can then be made more intelligible and there is less likelihood of misunderstanding.

THE occurrence of fine placer gold with fine gravel, and of coarse gold with coarse, heavy gravel, is due entirely to the sorting action of water, the finer gold being carried farther, together with the finer gravel, than that which is coarse and heavy. The working of placer streams proves this abundantly, the fine gold being carried much farther than the coarse. The size of all the material in streams decreases with increasing distance from its source.

MINIUM, a natural oxide of lead, is found in some of the mines of Leadville, Colo., recently in the oxidized zone of the mines of the Progressive Mining Co. The presence of minium in the ore deposits of Leadville was recognized in the early history of the district. It is a mineral of relatively rare occurrence and is more valuable for cabinet specimens than as a commercial ore. It is of vivid red color, sometimes mixed with the yellow oxide, and occurs pulverent or in crystalline scales.

THE pounding in an engine cylinder may be due to defective valve setting, but it may usually be ascribed to some other cause. If the machine is properly set and in line and well keyed it is not likely to pound. The frequent breaking of the pinion teeth is probably due to defective alignment. An engine cylinder a small fraction of an inch out of line with the crank disc will always give more or less trouble when long continued—that is, steady running, such as is usually done when unwatering a mine is necessary—and will heat the boxes under such conditions.

NEXT to quartz the most important rock-forming mineral is feldspar, particularly in eruptive rocks. The names of many igneous rocks is determined by the predominance of certain feldspars. The most important feldspar is orthoclase (potash feldspar), of which there are two kinds, orthoclase and sanidine. The former occurs in the Archæan and intrusive rocks and sanidine in the extrusives or those eruptive rocks which reach and overflow the surface, as trachyte, andesite, etc. This latter is usually associated with lime-soda feldspars of the plagioclase group.

PITCHSTONE contains no pitch or other carbonaceous matter. It is a compact, natural glass, with greasy resinous lustre. It occurs in beds or sheets, dikes and bosses. Hyalite is a glassy form of silica found in transparent and colorless form in basaltic lavas. Opal is an amorphous silica combined with water. It differs from ordinary quartz in being soluble in caustic potash, from which it can be precipitated by ammonium chloride. It occurs as an infiltration in vesicular cavities in trachytic rocks. It also occurs in "petrified wood," where the cellulose of wood has been replaced by the soluble silica.

FOR convenience in calculating the results of assays the assay ton is employed. It was devised by Prof. C. F. Chandler of Columbia College, New York. As ores of the precious metals, as well as those of base metals, are weighed by the avoirdupois system, while gold and silver are weighed in ounces troy, the basis of the system is the number of troy ounces in a ton avoirdupois of 2000

pounds, which is 29,166.66 ounces. The assay ton contains 29,166.60 milligrams. Hence if one assay ton of ore is taken for assay and a button obtained weighing 320 milligrams of gold, the ore contains 320 ounces of gold per ton, as each milligram in the assay ton is equivalent to an ounce troy per ton avoirdupois.

OF the seventy-one elements given in Dana's Mineralogy, five of them: oxygen, hydrogen, nitrogen, chlorine and fluorine, are gases; bromine is a volatile liquid; mercury is also a liquid, but all others are solids under ordinary conditions. The elements are divided into metallic and non-metallic classes. Metals are those having metallic luster, are malleable, opaque, conductors of heat and electricity, etc. The non-metals have none of these physical characteristics, being brittle, often transparent, and poor conductors of heat and electricity. The semi-metals, such as arsenic, antimony, bismuth, etc., have some of the physical characters of a metal, but are more or less brittle, and often take the part of an acid element in their combinations.

WHERE A locates a claim in Arizona in December, 1900, and performs the necessary "location work," records notices, etc., as required by the Territorial statutes, he is secure in his title until December 31, 1901, at midnight; but if he has performed no assessment work in 1901, as required by United States mining law, his claim is open to location at the date and hour above mentioned, and B locating in April, 1902, acquires the rights relinquished by A through failure to comply with the law. The subsequent return to the claim by A and the performance of any amount of work will not reinstate him in his forfeited rights. Had he, however, resumed work at any time in 1902, prior to the claim having been taken by B, he would have been secure.

HOUSEHOLD FILTERS are not often satisfactory. They must be cleaned frequently, and this with the ordinary home-made filter means a complete renewal of the entire filter bed. A filter when new will prove an excellent thing, but once fouled the filtered water is far worse than it would be without the filter. A filter made of sized gravel (coarse on the bottom) and charcoal makes a good household filter, but it must frequently be renewed. Little dependence can be placed on the various forms of stone and sponge filters, as they merely act as strainers and are quickly contaminated. Placing various chemical substances in water is too slow in its action to make it valuable. The best general remedy for water about the purity of which there is a doubt is to boil it.

WHERE tailings are permitted to run without obstruction onto the lands of others they become the property of the owner of the land, and where they accumulate upon unclaimed land they are subject to location in the same manner as placer claims. Where the deposit of mill tailings in a stream works an injury to another the case is actionable for damages sustained, but it is questionable whether under all circumstances a court of equity would find just cause for injunction. The court will consider the importance of the mining proposition and necessity for depositing tailings in the stream, as well as the injury done by them to others. While the miner is entitled to the free use of the stream to carry away his tailings, he has no right to fill the channel with debris, causing the stream to overflow and thus deposit the sand on the land of his neighbor.

It is difficult to prescribe a remedy to prevent "floured" quicksilver forming in a stamp mill without knowing all of the conditions under which the mill is operating. This must be learned by careful investigation. Some of the causes for this fine sub-dividing of the "quick" are too high discharge; too rapid drop of stamps, and consequently too violent churning of pulp in the battery; grease in the mortars from stems or elsewhere; overfeeding of "quick," with resulting soft plates; arsenical compounds in the ore, or in the water used; black oxide of manganese flours "quick." Sometimes mine water is employed in the mill, and causes the mercury to "flour" and "sicken." This was the case with a mine on Osborne hill, near Grass Valley, Nevada county, Cal., some years since, when mine water was employed in milling. Ore from the same stope sent to another mill gave good returns.

WHERE, in the progress of stoping ore from a vein or other mineral deposit, the workings reach the end line of a claim, the party removing the ore in the stope is required to give to his neighbor lateral support—that is, take such steps as seem necessary to prevent caving of the vein or ore body at the party line. Subsequently, should the face cave, and if the ore left standing falls into the stope previously excavated in the adjoining property, this ore is still the property of the person originally owning it; and should the party making the stope remove the ore and convert it to his own use, he is responsible to the proper owner for the value of the ore thus taken. The owner may remove the ore, however, through his own workings, even though obliged to go into the adjoining stope to recover the caved ore. Municipal law is the reverse of this, and the owner of a building adjoining an excavation must support his own walls and building.

IN steam boilers the usual value given to the term

"horse power" is the evaporation of thirty pounds of water at a temperature of 100° F. into steam at seventy pounds pressure above the atmosphere. The quantity of coal consumed in generating one horse power varies greatly, depending on the kind and condition of coal used, the size and kind of boiler, and to no small extent upon the method of firing—the personal equation being a large one where a mechanical stoker is not used. The most common causes for complaint in inefficient steam plants are poor draft, insufficient grate surface, poor coal, furnace not adapted to kind of coal, bad setting of boiler, leaks of air through brick work, improper firing, boiler too small, which means insufficient heating surface, bad water, and lack of water heaters and dampers in stack. The amount of coal burned per square foot of grate surface varies greatly. For instance, with good coal and a good boiler eight pounds of coal consumed per hour will require .43 square foot of grate surface per horse power generated, and forty pounds per hour will require but .09 square foot of grate surface per horse power generated. Thus it will be seen that power will be generated much more cheaply in a large boiler than in a small one. The cost per horse power of electricity depends entirely upon the power employed in generating it. The cheapest is undoubtedly that which is generated by the employment of free water power, and the most expensive that generated in a plant having inefficient boilers, poor quality of fuel and bad management.

THE table of hardness of minerals as given in "Dana's Mineralogy" is as follows: Talc 1, gypsum 2, calcite 3, fluorite 4, apatite 5, orthoclase 6, quartz 7, topaz 8, sapphire 9, diamond 10. The hardness is measured by the resistance which a smooth surface offers to abrasion. The degree of hardness is determined by observing the comparative ease or difficulty with which one mineral is scratched by another, or by a file or knife. When testing for hardness crystalline varieties with smooth faces should be taken as far as possible. Minerals of grade 1 have a greasy feel to the hand; those of grade 2 are easily scratched by the finger nail; those of grade 3 are readily cut by a knife blade; of grade 4, scratched by a knife; grade 5 is scratched with difficulty by a good knife; grade 6, barely scratched by a knife, but distinctly by a file. Minerals of this hardness will scratch window glass. Quartz, which has a hardness of 7, and all the minerals harder than quartz scratch glass readily, but are little touched by a file. The chemical composition of minerals seems to bear a direct relation to their hardness. Compounds of the heavy metals, as gold, silver, copper, lead, mercury, etc., are all soft, their hardness seldom exceeding 2.5 or 3. The compounds of the common metals—the sulphides (arsenides) and oxides of iron—are relatively hard, pyrite 6 to 6.5 and hematite 6. Nickel and cobalt are included in this class. The minerals which are conspicuously hard are found among the oxides and silicates, many of them being compounds containing aluminum, as corundum or sapphire, diaspore, chrysoberyl. The most common minerals having a hardness near or greater than 7, and having unmetallic luster, are quartz, garnet, tourmaline, spinel, topaz, corundum and diamond.

THE statutes of the State of Nevada provide as follows in the matters of making amended locations, or changes of boundaries: "If at any time the locator of any mining claim heretofore, or hereafter located, or his assigns, shall apprehend that his original certificate (of location) was defective, erroneous, or that the requirements of the law had not been complied with before filing; or shall be desirous of changing his surface boundaries, or of taking in any part of an overlapping claim which has been abandoned; or in case the original certificate was made prior to the passage of this law, and he shall be desirous of securing the benefits of this act, such locator or his assigns may file an additional certificate, subject to the provisions of this act; provided, that such relocation does not interfere with the existing rights of others at the time of such relocation, and no such relocation, or the record thereof shall preclude the claimant or claimants from proving any such titles as he or they may have held under previous locations." The law does not require that in making an amended location that the relocater shall state for what purpose he makes an amended location, but simply gives him that right, but does not permit him to appropriate any portion of a claim located by others, either prior to his original location or subsequently. Any rights or privileges obtaining under the original location extends to the amended location. All the assessment work for a group of claims may be done on one of them, but the work must be for the benefit of all, as a shaft on one of the claims where the same vein runs through all of the group. It is doubtful if the law would permit the work to be done on one claim where the several claims of the group were located on separate veins. The work may be done in a single tunnel to develop a number of veins lying beyond, and which are covered by several locations, as such tunnel development will manifestly be for the benefit of all the claims of the group. The discovery of a new or "blind" vein within the limits of a claim already located does not permit the owner of such claim to take anything beyond the boundaries of his original location, and in case of an amended location his privileges are confined to those lines. In no case can he encroach upon his neighbors. He obtains the extralateral right, however, the same as upon his originally discovered vein.

The Law of Faults.

Written for the MINING AND SCIENTIFIC PRESS.

The direction of throw of a faulted vein is not always easily distinguishable. Where the hanging wall and foot wall of the vein are wholly different, as lime on one wall and porphyry on the other, the direction of displacement is easily determined, but where both walls are similar, as slate or amphibolite schist, nothing but some sign of the direction of movement, such as the inclination of the contortion of the folds of the rock, or fragments of the faulted vein in the plane of faulting, affords a means of determining the direction of faulting. Faults are of two kinds, normal and reverse. In the former the hanging wall sinks relatively to the foot wall; in the latter, as the name suggests, the direction of displacement is reversed, and the hanging wall moves upward. This type of fault is also called a "thrust." Normal faults are of very common occurrence in sedimentary rocks, though reverse faults are also frequently observed. In crystalline rocks, however, the reverse or thrust fault is of very common occurrence. Sometimes faults stand vertical or nearly so, and the direction of throw in these is determined in the same manner as inclined faults. Faults do not always pursue a straight course, but change their direction in both strike and dip. In mines the veins are sometimes displaced by faults which have every appearance of veins, with gouge, crushed quartz and infiltrated calcite, etc., but contain no values. These the miners call "crossheads." The only distinction between a fault of this type and a vein is the lack of values in one of them, and the evident fact that one of them, usually the so-called "crosshead," is the younger—intersecting the older vein.

Veins are sometimes abruptly cut off by barren fissures and their continuation beyond is never discovered, but in most instances this is not the case. Faults are caused by internal stresses within the earth's crust, and the forces which produce the fissures which subsequently become veins by infiltration of gangue minerals and sulphides of the base metals, together with gold and silver, are the same as those subsequently producing the faults.

Such stresses are often evidenced along the plane of veins subsequent to their formation, this becoming apparent by the formation of heavy gouges, and polished surfaces in the quartz of the vein. Often this movement along the plane of the vein results in crushing the hard quartz into a mass of fragments, which become recemented by silica with more or less of the fine material derived from the walls of the vein, producing a mottled appearance. Rock of this description seldom has much value. At the side of a vein of this brecciated material may often be seen a banded, perfectly formed vein, that has apparently not been disturbed since its formation, and this may carry payable values in gold, both free and in auriferous sulphides. Veins of this description are not infrequently seen in California mines.

The stresses producing faults are not always sufficient to cause the rock to fracture, and in this event a line of torsion is the result. An instance of this character is found in the Ready Relief mine at Banner, San Diego county, Cal. There the rocks, mica slates, are contorted in a most remarkable manner, the result of a severe compressive stress, sufficient to crumple the slates, but not enough to cause an abrupt fracture. Along this line of crumpling and abrupt folding silica has been deposited in large quantities, in some places 20 feet wide, and with it gold and auriferous sulphides. In these "rolls" the structure of the original slates may usually be distinctly seen. Had this stress proceeded much further it would have resulted in the formation of a perfect type of fissure, having a dip of 45°, through a formation standing at about 70° from the horizontal. This folding must be the result of a long-continued pressure, for the rocks are not fractured, but bent and rolled upon themselves.

Were it not for the faults at Leadville, Colo., it is doubtful if the ore deposits there had ever been discovered. The ores occur in strata of limestone, intruded by dikes of porphyry. Other porphyry is injected in flat sheets between the several layers of the limestone and the quartzites of the region. The ore bodies are extensive, covering a large area, and occur at several geological horizons. It is believed that these ore bodies were formed at a depth of approximately 10,000 feet beneath the surface, then uplifted and the greater portion of the overlying strata eroded. The local faults displaced and folded the rocks of the district, bringing the ore beds to the surface in a series of steps, as it were, and it was the erosion of the exposed edges of these bedded deposits that furnished the carbonates of lead and galena to the placers of early days, the gold probably being mostly derived from the large ore bodies in the intrusive rocks lying east of the principal lead-silver mines.

Leadville owes much to the faults which made the deposits of ore available. The condition in that district is essentially the same as at Aspen, and in the northern portion of the Black Hills in South Dakota, and in some other mining districts where silver-lead ores occur in limestone with intrusive sheets and dikes of porphyry.

Faults are sometimes the result of local pressure,

as the mass of a mountain. A vein having its apex along the flank of a high hill or mountain and finding insufficient support on its lower side to sustain the weight of the mountain may be fractured and displaced from this cause. The Hillside mine in Yavapai county, Arizona, furnishes an illustration of this type of fault. The vein approaching the vertical in its dip is dislocated by a fault dipping westward at about 45°. This has resulted in the hanging wall side of the fault moving downward along the plane of the fault nearly 40 feet. At one place in the main gangway the fault was seen to displace the vein, but on the upper side of the fault plane was observed a vein within 2 feet of the vein below the fault. This upper section was apparently the upward continuation of the fractured vein beneath the fault, but had this been the case it must have been the result of a reverse fault. The condition of the wall rocks adjacent to the vein indicated that the fault was a normal one, and the section of the vein found above the fault plane was consequently considered as belonging to another vein lying to the eastward. A crosscut run subsequently determined this to be a fact. The wall rocks of the Hillside mine are in most part a light, silvery gray phyllite, dipping a few degrees from the vertical. Along the fault plane the folds of the rock were flexed by the movement, those on the upper or hanging wall side of the fault bending to the eastward, and those underneath the plane turned to the westward, so that in the face of the drift the formation locally had the appearance of lying flat.

Veins are frequently found displaced in mines, but, as previously stated, occasionally, unless some physical index remains to show the direction of "throw," it can only be determined by actual exploration. There is no "law of faults" which can be relied upon. The miner must study the indications as developed in his workings, and if these indications are lacking he must necessarily work out his own salvation. A knowledge of geology is very useful in studying faults. A great deal of time and money have been wasted by fruitless search for a dislocated vein by seeking in the wrong direction.

Natural Hydraulic Cement.

Natural hydraulic cement is made by burning lime rock which contains lime, silica, alumina, besides magnesia, iron, alkalies, etc., varying in quantity within tolerably wide limits.

The proportion of clay (silicate of alumina) combined with the lime in natural cement, it is claimed, should be 35% to 40%. Analyses of some of the best grades of natural cement are shown in the accompanying table.

The rock is quarried, broken and burned in a manner similar to that used in the manufacture of lime, but the burning is carried to higher temperatures. The burned material is ground to fine powder—the finished product—which, when properly mixed with water, will set, making a rock of stony hardness, and will endure for a long period either in air or water. It must be true, however, that a natural cement would ordinarily contain inert an excess of one or more of the substances used in its production, since the true combining proportions of a hydraulic cement can vary only within narrow limits.

An enormous quantity of natural cement is produced annually and used in all kinds of construction where hydraulic cement is in demand.

ANALYSES OF HYDRAULIC LIMES AND NATURAL CEMENT.

No.	Silica	Alumina	Iron Oxide	Lime	Magnesia	Carbonic Acid Water and Loss	Alkalies
1	24.33	1.92	...	71.91
2	29.71	5.35	3.29	59.53	9.95
3	28.39	11.71	2.29	43.97	2.21	2.44	9.00
4	26.69	7.21	1.30	43.12	19.55	1.00	1.13
5	30.00	11.00	1.50	34.00	16.00

1. Hydraulic lime, Lyme Regis, England. Used in the construction of London docks.
2. Eminent hydraulic lime, Hollywell, Wales. Used in the construction of the Liverpool docks.
3. Cumberland hydraulic (natural) cement, Cumberland, Md.
4. Akron hydraulic (natural) cement, "Cummings," Akron, N. Y.
5. Average natural cement. From Architects' Hand Book on Cements.

THE most widely spread of the iron bearing rocks of Ontario, as well as of the adjoining States, are siliceous, commonly of jasper or chert or white or gray granular silica, finely interbanded with magnetite or hematite, the whole usually more or less crumpled or brecciated and standing nearly vertical. The unchanged iron range rock seldom carries iron enough to be an ore, running usually below 35%, though some magnetic banded ores seem almost rich enough to be mined. The siderites often associated with them are not considered pure enough to be used as ores, since they are generally siliceous and contain considerable quantities of pyrites.

Stamp Milling and Amalgamation of Free Gold Ores.

NUMBER VI—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by DANA HARMON, San Francisco, Cal.

CONCENTRATORS.—Concentration is too broad a question to be discussed here; so much depends upon the characteristics of the metals and the gangues. In too many mills the crew is inadequate, so that both batteries and vanners suffer alternately as the solitary millman plods up and down stairs vainly attempting to do the work of several men. I have never seen a dozen belt vanners in any mill all working right for over five minutes at a time. For the average mill, and especially for the small mills, the concentrator should not be oversensitive; there is a wide difference in this respect between the various belt vanners. Don't pay much attention to the advertised competitive test records. What is wanted is a machine that will not go awry at every little variance of pulp, and that will carry a heavier load. The belt vanner requires some experienced hand at its side all the time.

I am glad to note that during the past two years there has been marked advance along the lines of the shaking tables of the Wilfley type. There are now on the market several styles, rectangular or circular, similar to the Wilfley, and the latter is itself a much better made machine to-day than it was two years ago.

Manifestly concentrators of this type, with the wide range in load of twenty to forty tons, will not be going wrong every five minutes. By supplementing them with classifiers, it is now possible to handle a hundred or more tons per day with greater precision and less trouble than we could ten tons formerly.

Where machinery is going constantly, the fewer parts to the machine and the fewer machines the better for the business. This is precisely the modern tendency in concentration. It would look as though the oil process of concentration was destined to satisfy some conditions where water concentration wholly fails.

COSTS.—Costs are always interesting as being the final test of value to our efforts and theories. I may therefore be permitted to give the results of one year of my work on a free milling ore with twenty stamps crushing 22,000 tons: Two amalgamators at \$3 50 each, and four helpers (includes rock breaker men) at \$3 each. Power water was bought; battery water came from the mine; in a deep snow country—4600 feet altitude. The quicksilver loss includes the mechanical losses from retorting, cleaning up, etc. The ore averaged \$4 65 per ton, only three of the twelve cleanups exceeding \$5 per ton. The tailings averaged about 15 cents per ton:

Water power—rock breakers	0093
Water power—batteries	0745
Labor, all including repairing	2112
Shoes and dies	0701
Mortar liners	0077
Replanting	0143
Rock breaker jaws, tappets, bosses, belting, extras, etc.	0287
Oil, lubricating	0031
Oil, lighting	0065
Screens, tin No. 2	0033
Quicksilver loss, .15 troy oz. per ton	0050
Firewood for stoves	0095
Sundries	0079

Total per ton..... 4491

The rock breaker costs were excessive because the ore was very tough as well as hard and the rock breakers were not as large as the ore required—they were therefore under heavy strain at all times. This is not an uncommon difficulty at a large number of mines, and should be at none.

RECAPITULATION.—To recapitulate; my argument runs in about this wise:

Use a stamp mill because no better machine for the purpose in hand has been invented.

Use a heavy stamp because it won't waste time and can be run slow enough to save wear and yet fast enough to churn and therefore amalgamate.

Have large shoe and die areas, so as to embrace plenty of rock at every blow.

Crush and also amalgamate, the limit of your crushing to be taught by the tailings assays.

Extract all the practically recoverable gold. If more stamps are needed, build them.

The speed and drop suitable can only be determined by assaying tailings.

Catch the gold close to the die.

Renounce chock blocks.

Don't slime by too fine crushing.

Beware of too much water.

Don't crowd the plate with too much pulp.

Have the plate sticky and pasty with amalgam, and never dripping with quicksilver.

Use a broad, steep plate and hang up when rub-

bing up; note the use of the word ruh, not wipe. Put elbow grease, and none other, on the plates.

Don't be parsimonious about replating.

Keep the quicksilver clean.

Sample automatically.

Battery water temperature not below 50° Fahr.; better at 65° or 70°. Use clean water only. Avoid slum water if possible.

Let your millman swallow all the patent medicines his stomach craves, but don't let him work off any nostrums and acids on your plates.

The Development of High-Pressure Centrifugal Pumps.

Written for the MINING AND SCIENTIFIC PRESS by
JOHN RICHARDS.

It is common opinion throughout the Eastern States that centrifugal pumping has reached a more advanced stage on this coast than in other parts of this country, and this is certainly true in respect to many, if not most, of the varied uses to which these machines are applied, especially as to an early use of the high-pressure type that is now engaging especial attention in all countries.

The writer has been several times requested to explain this matter and give some of the facts relating to this "evolution," especially in respect to what are called high-pressure centrifugal pumps. This I cheerfully do, because the principal facts and data are ascertainable, and in a few years will be lost, as is common in such cases; also for the reason that some legal proceedings now being conducted in the East involves the origin and progress of these pumps in this country.

Down to 1880 there had not been any regular manufacture of centrifugal pumping apparatus on

of the San Francisco Tool Co., of this city, was called upon to examine a pumping plant employed to drain one of the San Joaquin islands, near Stockton, that belonged to some of the shareholders of the San Francisco Tool Co.

The machines in use were found to be imperfect, and the writer recommended that a new and better pump be procured from one of the Gwynne firms, at London, with whose work he was familiar. There was no time for this, however, and he undertook the construction of a cheap centrifugal pump, which, with a new steam engine, removed the water and at the same time reduced the coal consumption from 4500 pounds to 1800 pounds per day.

This circumstance led to a contract with the city of Sacramento for a vertical draining pump to clear the surface water at the southeast end of the city; and this again to other pumps, especially for irrigating purposes, until a regular business was established, the San Francisco Tool Co. being sole makers on this coast.

Up to 1883, it was a common belief, even yet entertained by many people, that centrifugal pumps can not be operated against a head exceeding 40 feet; but, in October of that year, Dr. Chapin, who held the position of State Entomologist in California, called at the works to ascertain whether he could not procure a series of such pumps to raise water 83 feet on his ranch near Santa Clara, Cal.

I had little faith then, and now, in series pumps operating at different levels, and proceeded to design a pump, as shown in Fig. 1, in which the water passed consecutively through two impellers without being diverted from its plane of revolution normal to the axis.

Working drawings and a pump were made from this sketch and the pump was started at the Tool Co.'s Works in Stevenson street, by A. F. L. Bell, now of this city, first as a single pump, with one impeller left out.

The pressure attained at the speed arranged was

there, and a mechanic with whom a contract was made to construct a large two-stage pump to operate against 90 feet of head and raise 750 gallons per minute. This pump is shown in Fig. 2 and it is to be questioned if there has ever been another made with more precision and the same care in workmanship.

The work done by the San Francisco Tool Co. was at that time of a very high grade, mostly on machine tools, and the pump was as well made as an iron lathe or planing machine. It was erected in a narrow pit 80 feet below the surface, in a fixed position, and the season being a very dry one the water rose over the pump and there remained for ten years or more, the pump running each year from two to three months, night and day, raising sometimes at the rate of 1000 gallons per minute, and receiving during this time no repairs whatever, not even examinations, being submerged and inaccessible.

This is an example of endurance that proves the advantage of good work and strong proportions, but is by any standard a strange result. In 1898, after fourteen years of service, this pump was dismantled and raised to the light again. All the bolts and attachments had to be cut away because of corrosion, but the main parts were preserved by Louis Booksin until the present month, and have been purchased by the Turbine Pump Co. of New York, as a memento of early practice in stage pumping. The drawing, Fig. 2, was made from these parts.

In 1885 I went to Europe and made there some investigation and inquiry respecting centrifugal pumping, but found that no stage pumps were in use at that time, and it is a fair inference that the pumps above referred to were the first to be practically and continuously operated.

With the exception of some special pumps designed between 1885 and 1900, I gave no special attention to centrifugal pumps until the advent of the stage pumps of Messrs. Sulzer Bros. of Switzerland, who produced a refinement in such machines by a purely scientific treatment of construction that differed in respect to water ducts of careful proportions, a great increase in the rate of rotation and in the diffusion of water from the impellers that converted its kinetic energy into pressure.

This was an important advance; one that called for accurate and intricate workmanship, that however easy it might be attainable in this famous works was not attainable in common shops. In that year I set about an attempt to balance the impellers of stage pumps, to simplify and cheapen their construction, also attain an equal pressure on the sides of the impellers to prevent circulating leakage.

After several years of experiment these things have been accomplished in such degree that a new type of high-pressure pumps will soon be so far perfected that their construction can be submitted to the world through the usual channels.

Engineering effort in this direction on the Pacific coast is to a great extent a sequence of the extended use of water-raising and impelling machinery demanded by the physical circumstances of the country and its industries.

San Francisco, Cal.

Pyrites Deposits in Alameda County, California.

Written for the MINING AND SCIENTIFIC PRESS by
R. P. MCLAUGHLIN.

The Leona Heights pyrite mine is situated 4 miles east of Oakland, Cal., in a region commonly supposed to be worthless from the miner's standpoint.

A body of massive iron pyrites about 50 feet wide has been opened to a depth of 100 feet by two tunnels and a winze. The country rock is the metamorphic sandstone commonly found in the Coast Range of California, having been much folded and crushed. The hanging wall is black and schistose and soon crumbles upon exposure to the air. About a foot of white clay gouge frequently lies between the ore and hanging wall. The foot wall is soft, white clay. The sulphide is soft and crumbling on the foot-wall side of the ore body, but is hard and has to be blasted on the hanging wall side.

The mine has been substantially timbered. The walls stand well in most places, but in the ore body close lagging is usually required. Where stoping is going on square sets are put in. Fifteen men are employed in the mine. No inconvenience is experienced from water, the mine being dry.

The ore was formerly trammed out in cars and dumped into a bin, from which it was drawn into wagons, but a wire rope tramway has recently been installed, which will convey the ore about a quarter of a mile to the electric road running to Oakland. An endless 1-inch cable carries twenty-five automatic dumping buckets having a capacity of a quarter of a ton each. Power for the tramway is supplied by an electric motor situated at the upper end of the system.

The pyrite is treated at works on the shore of the bay. The chief demand is for the manufacture of sulphuric acid.

Several other localities in California furnish pyrites, notably the Iron Mountain Copper Co. of Shasta county and the Spenceville mines in Nevada county.

FIG. 1.

FIG. 2.

this coast. A great many of a cheap kind were imported here to replace reciprocating pumps for irrigating purposes, because the water when drawn from the gravel strata was filled with sand and fine gravel that soon cut away packing and destroyed sliding joints of any kind exposed to the water.

It was soon discovered that centrifugal pumps had no sliding contacts, no valves, and were not affected by the sand and gravel, and besides could be employed for large quantities of water. This and other reasons lead to the manufacture of such machines here, the circumstances being as follows:

In 1880, the writer, then a director and manager

30 pounds per inch. The second impeller was then put in and the pressure rose to double, or 60 pounds per inch, and a telegram was sent to Dr. Chapin saying the company would contract for a pump to operate at a head of 85 feet.

This pump was made, and erected in February or March of 1884 by C. H. Gorr, of San Jose, and was perhaps the first stage-centrifugal pump set in practical operation in this country having the distinct features of present practice, including the division plate and return passages between the impellers.

This pump attracted the attention of Henry Booksin, of San Jose, a prominent fruit grower

An "All-Fire" Method for the Assay of Gold and Silver in Blister Copper.*

By WALTER G. PERKINS, Grand Forks, B. C.

As this particular product holds a place by itself, it seems desirable to give a paper dealing especially with it. The process is first to convert the metallic copper into matte by the addition of sulphur, allowing the two elements to combine at the bottom of the crucible when heat is applied. The flux then acts on the sulphides, oxidizing some of the copper which goes into the slag, while the gold and silver are collected in the lead-button reduced by the sulphur. These buttons are combined and scorified twice, for the purpose of concentrating the values and eliminating the remaining copper, thus reducing cupel absorption-loss to a minimum.

CHARGE FOR A 20-GRAM CRUCIBLE.

Sulphur.....	800 0	mg.
Cu (approx.).....	0 083	A.T.
Na ₂ CO ₃ +K ₂ CO ₃ (½ and ½).....	0 5	A.T.
PbO (free from Ag).....	8 0	A.T.
SiO ₂	0 5	A.T.
Salt Cover.		

METHOD OF OPERATION.—Weigh out 0.25 A.T. of copper borings, divide it approximately into three equal parts, and place in 20-gram crucibles; repeat the operation until four sets have been weighed out, thus having twelve crucibles in all for one assay. Weigh 800 milligrams of pulverized sulphur into each of these and mix with the copper; then add one charge of flux, but do not mix the copper and sulphur with the flux, as these two elements should remain at the bottom of the crucible, to form matte when heat is applied. Shake down; fill the remaining portion of the crucible with salt (NaCl), and place in a dull-red muffle. Raise the temperature gradually for thirty or thirty-five minutes, at the end of which time some salt should remain, not quite molten, in the center of the top of the charge; this will melt and become fluid in a few minutes. The temperature should then be raised, so that, in forty-five minutes from charging, the muffle will be of a bright red color, the charge quiet and perfectly fused.

The success or failure of this method, especially the silver result, depends upon the proper regulation of the furnace. Therefore, a detailed description of the manipulation, as practiced by the writer, is necessary at this point.

The muffle used is 17x19x8½ inches, outside dimensions, in which twenty-five crucibles can be placed at a time. Twelve crucibles containing the blister copper charges should be placed in the front part of the muffle, so that the action can be watched carefully. In the back part of the muffle may be placed ore assays, etc., the results of which are not so easily affected by temperature.

The atmosphere in the muffle must be reducing; otherwise, as the charge fuses, the silver seems to come to the surface, and a portion of it is apparently oxidized (or volatilized) and lost in the slag, making the result from 0.4 to 1.0 ounce per ton too low. A muffle that has a good draught through it always has an oxidizing atmosphere when fired with coal; therefore, some artificial means must be resorted to in order to bring about the desired result. The practice here is to plug the holes in the back of the muffle with honeash. Then distribute five crucibles (which are about three-fourths full of fine coal and covered with 3 inch scorifiers) amongst the charge, thus: Two in the back row, one in the center and two in the front row of crucibles, closing the front with a tight-fitting door. This will reduce one to two grams of Pb from PbO, if a blank charge is run. In case a gas or gasoline furnace is used, the atmospheric conditions would probably be correct without resorting to artificial means.

POURING, SLAGS AND BUTTONS.—All conditions being perfect, the charge will pour very fluid. But care must be taken to rotate the crucible quickly, and tap sharply several times, in order to settle any fine shots of lead that may otherwise be held in suspension or adhere to small recesses in the walls or bottom of the crucible.

The slag, on cooling, should be a yellow silicate of lead at the outside of the cone, becoming finely crystalline and deep green immediately inside the outer skin. If more than merely the skin of the slag shows as a silicate, the heat has been too great; and if the entire slag is crystalline, with large coarse crystals pointing towards the center, the temperature has been too low, and has probably left some shots of lead in the crucible. The salt on the top of the cone will be of deep brownish red, the depth of color lessening when overheated or when the atmosphere of the muffle had an oxidizing effect.

The button from each crucible should weigh about eighteen grams, and break clean and bright from the slag. Care must be taken that a film of lead is not left on the slag where the button breaks from it, as a gas bubble that has a thin covering of lead appears to form at the top of the button, which adheres to the slag.

SCORIFICATION.—Each set is now represented by

three buttons weighing eighteen grams each. These are now scorified, to eliminate more copper and concentrate the values. The four sets, each representing 0.25 A.T., are manipulated as follows:

Place four 3-inch scorifiers in a hot muffle for ten or fifteen minutes; then, having reduced the temperature in the muffle to about the right heat to open cupellations quickly, place the sets of three each in the four scorifiers; close the door and the scorifications should open as quickly as cupellations. When properly opened, lower the temperature to a heat that will just permit the operation to be carried on successfully until covered. Raise the temperature until the slag is hot enough to pour freely; decant as much slag as possible without losing any lead; return the scorifiers to the muffle and allow scorification to go on until again covered; close the door to heat up the slag, and then remove the scorifiers and pour. Each resulting button will weigh about five or six grams, if the temperature has been kept low from the start.

SECOND SCORIFICATION.—Four 2-inch scorifiers are now heated as before. The buttons from the first scorification are broken down and the slags scraped free of any lead films on to a filter paper. Each 5-gram button is made up to twenty-five grams with C.P. test lead. The filter paper containing the button and test lead is folded and put into the hot scorifier. Conduct the operations at as low a temperature as possible, as these buttons will open easier than the first scorification. Raise the temperature when the buttons are nearly covered with slag, pour, cool, and break down again, watching for small amounts of lead on the slag.

These buttons are now ready for cupellation, and represent four assays of 0.25 A.T. each. Carry on this operation to get "feather" PbO on the cupels. This needs careful watching, as the buttons only weigh five or six grams. Weigh the heads for silver plus gold in 0.25 A.T. Combine two and two, part, and weigh for gold in 0.5 A.T.

SUMMARY.—1. The litharge must be absolutely free from silver, or, at the most, contain only small traces of silver, in order to avoid the necessity of correcting by difference. The kind used is of Pueblo manufacture.

2. The temperature must be carefully regulated in all operations. Also, have a slightly reducing atmosphere in the crucible operation, otherwise the silver result will be too low.

3. Great care must be exercised in watching for shots and films of lead, especially after the concentration of sets.

4. The cupels should be nicely "feathered," and when cold should be of a very pale greenish yellow, denoting the almost entire absence of copper. It is possible to get a good result by leaving more copper in the lead button, thus doing away with the second scorification. It is best, however, to do as directed, placing beyond doubt the question of the absence of copper in the silver heads.

5. The flux can be mixed in large batches and measured by having a cup made that equals one charge, the formula being:

Na ₂ CO ₃ +KCO ₃ (½ and ½).....	5 pounds
PbO.....	80 pounds
SiO ₂	5 pounds

6. The advantages of this method are:

That it gives results in gold equal to the "all-scorification" method, and in silver equal to the combined wet and fire method.

That it does away with the necessity of making separate estimations for gold and silver, thus saving the time and expense of working the combination method for silver.

That the time taken is less for each estimation than in the all fire scorification. In practice it takes from five to six hours to do three determinations of gold and silver.

Renewed Interest in Tin Mining.

The one metal absolutely necessary in the production of staple manufactures which has not been produced in this country to any extent is tin. Attempts have been made quite frequently to develop the deposits of this metal which have been discovered in various sections of the United States, but in almost every instance the deposits have either proved too lean to work satisfactorily, or the companies undertaking the problem of conducting operations have not had sufficient capital. It is interesting to note that renewed attention is now being displayed in this direction. Companies have been formed for operating in South Dakota and southern California, and they are announcing with confidence that they have not only satisfactory deposits of tin ore, but that sufficient capital has been secured to enable operations to be successfully prosecuted. It is to be hoped that the expectations entertained by these companies will be realized, and that this year may see tin produced on a commercial scale in the United States. This country is the largest consumer of tin in the world, and it would be decidedly beneficial to the consuming interests if this essential metal could be produced at home.—Iron Age.

An Automatic Tripping Device.

The Sherman automatic ore bucket tripping machine is illustrated herewith (Fig. 1). At the bottom of

FIG. 1.

the automatic tripper is fastened a heavy hook, which is hooked to the hals of the ore bucket or other receptacle. The buckets, together with the automatic tripper, are elevated and conveyed along the cable to the dumping place, when the bucket, together with the tripper just above it, is lowered, when the tripper by an automatic device will trip or empty the bucket at any point desired between the cable and the receiving bin below. At first the automatic tripper is set so as to dump the bucket close to the ground. As the pile increases in height the tripper can be changed so as to dump the bucket higher up. It can be changed to dump at any point by loosening a handwheel and changing the position of the pall. It requires no hand labor in emptying the bucket, an important item in handling ore, especially when emptying into cars from boats. The manufacturers state that it is strong and substantial and not

FIG. 2.

liable to get out of order. Fig. 2 shows the bucket just after being tripped or emptied by this automatic device. It is manufactured exclusively by the C. O. Bartlett & Snow Co., Cleveland, O.

Separation of Zinc Ores.

A new process presenting many remarkable features has been invented by G. D. Delprat and Mr. Carmichael of the Broken Hill Proprietary mine for separating particles of blende from the waste material of the concentration mills.

The principle of the process is simple. It has been found, that under certain circumstances, the particles of blende will float, while those of the rhodonite and quartz, which constitute the greater part of the remainder of the gangue, remain at the bottom of the liquid. This result, however, is not attained without a certain amount of chemical action, and this chemical action is rendered possible by the presence in the blende of a small proportion of sulphide of iron. Following well-known chemical laws, zinc sulphide in contact with certain acid solutions generates sulphuretted hydrogen gas. If the solution be sufficiently viscous, and the particles of blende sufficiently minute, the bubbles of gas remain attached to them, and raise them to the surface of the liquid, where by very simple devices they can be collected

for further treatment. During the experiments, which at the suggestion of Mr. Delprat were carried on by Mr. Carmichael, it was found that when the waste material from the mills, which, of course, was already finely comminuted, was subjected to the action of a hot solution of salt cake of rather high density, the particles of blende quickly rose to the top of the liquid in the manner described. This feature, which in laboratory practice would probably be regarded as an annoying hindrance, suggested a mode for separating the blende in larger quantities, and a small plant was devised to ascertain whether this is feasible. Experiments which succeed fairly well in the laboratory do not always bear out the expectations which have been formed concerning them, when attempts are made to put them into practice on a commercial scale.

The apparatus consists of a vat containing a solution of salt cake, brought by the addition of other salts (which are of an inert character), to a specific gravity of about 1.4 B. The solution is raised to a temperature of 195° F., and the bath is charged with waste material to a depth of about 1/2 inch. Separation begins immediately and the particles of blende rise to the surface. An additional quantity of the salt cake solution is poured into the bath, and the overflow carries the blende, which has thus been raised to a proper receiver, the salt cake solution as it drains away being again utilized in the bath. The process, it would appear, can be carried on either intermittently or continuously. Both the zinc product and the tailings or residue are afterwards washed in order that the salt cake adhering to them may be recovered by evaporation. By this expedient the loss of chemicals is small. It is also possible, Mr. Delprat states, to recover either zinc or lead ores by the use of nitric acid and nitrate of soda.—Australian Mining Standard.

The Friction of Steam in Pipes.

Among the theses presented by the class of 1902 of the Virginia Polytechnic Institute was one by W. L. Obewning and W. P. Tams, Jr., on the friction of steam pipes. This contained several diagrams plotted from tables prepared particularly for the use of designers of power plants sent to the Engineering Record by Prof. L. S. Randolph because of the use

pressure in pounds per square inch causing the motion, d is the diameter in inches of the pipe, w is the density of the fluid in pounds per cubic foot, and l is the length in feet of the pipe. If W is the total weight of the fluid discharged per minute, $Q = W \div w$, and the equation can be written in the following form, $p = W^2 w l + c^2 w^2 d^5$, but $W = k w d^2$, where k is a constant, hence

$$p = k' w l v^2 + d \quad (2)$$

If formulas 1 and 2 are compared, it will be seen that the only difference in form is the introduction in the latter of the density. According to the Italian experiments, the value of c in $Q = c \sqrt{pd \div w l}$ is 58, and this value might be used in determining k' .

A modification of this formula was introduced by G. H. Babcock and used by him in the computation of his well-known tables issued by the Babcock & Wilcox Co. It is

$$W = 87 \sqrt{(w p d^5 \div 1 [1 + (36 \div d)])} \quad (3)$$

Comparing this formula and that of the Italian authorities, it will be seen to allow for a variation of the constant for different sizes of pipes. Thus, for a 1-inch pipe, the constant would be 40.5, for a 3-inch pipe 58.6 and for a 10-inch pipe 74.8. This formula was employed in computing the tables plotted in the accompanying diagrams. For changes in the initial pressure multiply the values in the diagrams by the ratio of the densities at the new and old pressures. The loss caused by a globe valve is stated to be about equal to $114d \div (1 + [36 \div d])$. The loss caused by elbows is two-thirds that due to globe valves.

Winding Plants for Great Depths.*

There is much in suggestions made by Mr. Behr with which I cordially agree, among other matters the recommendation to investigate the requirements of every particular case before discussing the winding engines required. The requirements that the writer wishes to be most discussed are the conditions ruling on the Witwatersrand fields. To make this intelligible to those who have not visited them, or have not specially studied them, it will be necessary to bring forward some facts and principles.

The gold on the Witwatersrand is contained in beds

future, the earlier accounts showing expenses as high as 50s to 60s, whereas the monthly returns given by fifty-six companies for 1899 indicate an average working cost of 27s per ton. Consequently, judging from the past, and assuming an equal yield for the future, a deep level proposition would have as a basis for estimation, for moderate depths, a deposit capable of yielding an average return in profit of say 14s 6d per ton; for the entire section alone, a profit of 17s 6d per ton.

Working at great depths is handicapped by the following factors: The greater length of time necessary to make the ore deposit interest producing; the liability of encountering temperatures detrimental to economical working; the danger of encountering great quantities of water and the extra cost of pumping; the extra cost of hoisting ore, men and materials.

The first factor is pertinent to this discussion. It is clear that no delay must occur due to inefficiency of the winding plant, and that system of sinking must be adopted which will insure the greatest speed, for it must be remembered that the sooner the treasury is unlocked and made interest producing the more valuable it will be, and thus, even at the expense of greater cost, every possible effort should be made to reach the reefs as soon as possible.

Factor No. 2 has no direct, but an indirect, bearing on the subject of winding plants through ventilation. It is, of course, desirable to minimize the temperature underground by bringing large quantities of cooler air from the surface. This factor would thus enter into the proportion and size of the shafts to be adopted in connection with deep winding, and it is obvious that the system of winding which least impedes ventilation will be desirable.

Factor No. 3 has a most decided and vital bearing on the designing of hoisting plants. It is considered by many competent engineers that a well-balanced hoisting engine can raise water through a straight shaft from great depths at almost as low a cost as any pumping plant that has been designed. It is also most vital for these fields on account of the existence of acid water. Some mines, such as the Robins-Gold Mining Co., have suffered such inconvenience on this account, by corrosion of pump valves, chambers and pipes, that they, even now, are making preparations to handle their water in this manner. It is also an enormous advantage, in connection with the sudden inflow of water, to have a system which will aid the pumping plant in an emergency. Certainly the two-stage system of hoisting is very deficient in dealing with this problem, which makes it almost imperative to use the single stage where possible.

These statements of the Rand conditions show that there is no great margin for extravagances in any line if the proposition of deep mining is to be made attractive to capitalists. It is self-evident that the sinking of large deep shafts, and equipping them with the necessary pumping, hoisting, air and electrical power, requires very large outlay, and that the fewer of such shafts that a company possesses the more profitable will be the venture.

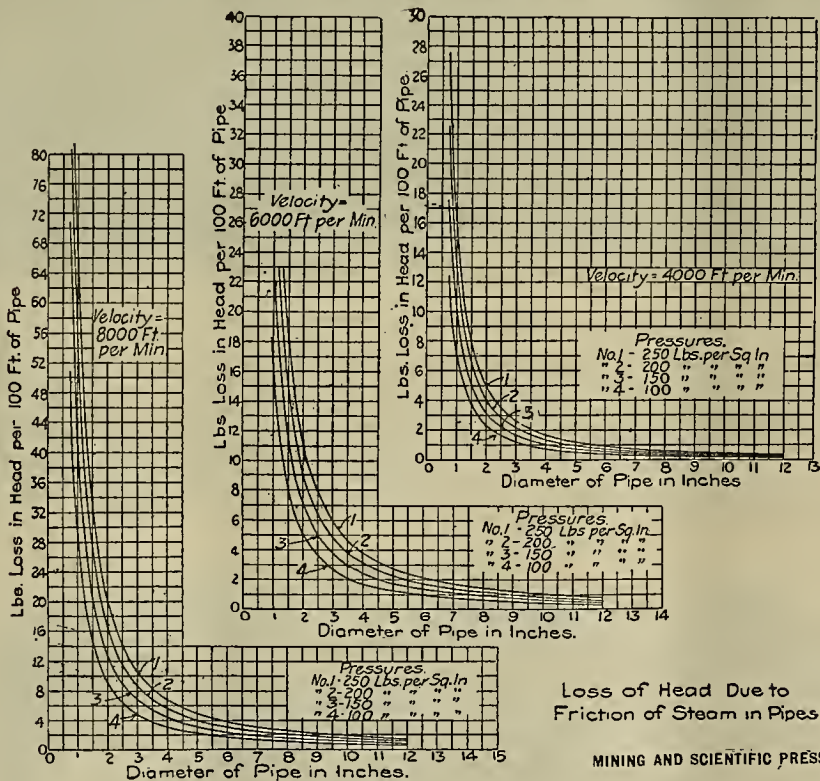

The average companies respectively have a claim area of about 185 for parent or outcrop companies, 216 claims for the first row of deep levels, and 291 for the second row. The tonnage that a claim will produce is not only dependent on its area of 60,000 Cape square feet, but also on the dip of the reef, its width, and its freedom from dikes, faults and barren ground. We shall assume for an average milling basis 30,000 tons per claim, allowance being made for sorting, faults, barren ground, etc., and a dip of 26°.

In the central portion of the Rand the existence of the reef has been tested by the Turf Club borehole to a depth of nearly 5000 feet. The horizontal distance from the outcrop to this borehole is 8565 feet, and the average dip of the reef from the apex to the point where it is intersected by the borehole is 29°, but, estimating the dip from the lowest workings shown in the Ferreira Deep shaft to the bottom of the borehole, the inclination of reef is about 26°.

With these facts before us, the questions to be settled are what is the most advantageous area for a deep level company, and what demands will be made on hoisting engines which are designed to exploit it.

The first condition for a deep level company is that it should have shafts capable of exploiting and ventilating its mining area, and thus be self-contained, and that it should make the maximum use of its costly vertical shafts. Thus we will assume two shafts (it is practicable to join them expeditiously when 3000 feet apart) of a maximum depth of say 5500 feet, and large permanent inclines extended on the average dip of the reef, but not following its faults and sinuosities. In connection with these main inclines it will also be necessary to have three subsidiary inclines, which need only be equipped with light hoisting machinery to command a depth of say 500 to 1000 feet, and at each 1000 feet the engines can be lowered. Trimming to the main incline shafts from the subsidiaries can also be done mechanically. The subsidiary inclines would be flexible, and could be placed to the best advantage in accordance with the mining conditions met with. The number of claims would be approximately 600.

The system of subsidiary inclines has the advantage in contradistinction to a greater number of shafts

ful data it contained. The introduction explains the general form of the equation for the flow of steam by comparing it with that for water. For the latter, assuming there is no friction, h , the loss of head, is equal to $v^2 \div 2g$ by the law of falling bodies. Friction exists, however, and varies directly as the length, l and inversely as the diameter d , so that the actual flow is more closely represented by $h = flv^2 \div 2gd$. Since $2g$ is a constant, this equation can be reduced to the well-known Weisbach expression

$$h = flv^2 \div d \quad (1)$$

As water is almost incompressible, its density is not taken into account, but this must be done when the flow of steam is considered and the above formula modified accordingly. Experiments made under direction of the Italian Government many years ago show that the usual formula for the flow of compressible fluids through pipes could be used for steam. This formula is $Q = c \sqrt{(pd \div w l)}$, where Q is the volume in cubic feet per minute, p is the difference in

of conglomerate composed for the most part of quartz or siliceous rounded material. There are several series of beds, but the one in which most gold occurs is known as the main reef series, which is divided into several hands. This series, as worked, shows on an average two beds justifying exploitation. Their distance apart varies from a few feet to 200 feet. The thickness of a payable reef varies from a few inches up to 12 feet. As an average, it may be considered that the two reefs will give a width justifying stopping of say 8 feet. These beds have been traced for a great lateral extent, the distance from Randfontein to Modderfontein along the line of strike being 53 miles. The section which is considered most reliable, and in which one profitable mine follows another almost without a break, is between the Langlaate Estate mine on the west and the New Comet on the east, a distance of 15 miles.

Working expenses in the early history of the fields were very much higher than they should be in the

*Hennen Jennings, in the London Mining Journal, (condensed).

connected with the surface—in fact, they can be made to conform to faults and disturbances met with, which could not be calculated upon in starting work from the surface.

The main shafts from the surface have seven compartments, and are 42 feet by 6 feet 6 inches in the clear. Shafts of this size are suggested for the following reasons: A large compartment is required for the necessary ladderways, air pipes, electrical cables, etc. Two hoistways will be necessary for the lowering of men and material, and two hoistways will be necessary for the winding of ore and water. The remaining two compartments are suggested with the object of improving the ventilation, and as a reserve in case it might be advisable to employ another winding engine either for water or ore, or both. These reserve hoistways can at first be bratticed, and, in connection therewith, an exhaust fan can be installed. The artificial ventilation thus introduced will greatly aid the speedy connection of the two main shafts and improve the ventilation of the whole development work prior to the two shafts being connected and the establishment of ample winzes.

When the connection has been made and ventilation established, a second hoisting engine can command these two extra compartments if the mine requirements justify it, and, even if the compartments are not required for further hoisting, they will aid the natural ventilation.

With the thin reef shown, the question arises: How many stamps can all these points of development employ, and when can they be started? The vertical shafts might be sunk and the necessary development work accomplished to start 100 stamps in say seven years, 200 in eight years, 300 in ten years, and 400 or 500 stamps between eleven and twelve years after the work was first started.

Let us assume that one hoisting engine at each shaft could deal with the ore problem up to 300 or 400 stamps, and we find that 300 stamps require a maximum of 42,500 tons of rock per month (weight of stamp 1250 pounds). If the ore is subjected to a sorting of 25%, on the surface, we should have to take from the mine 14,166 additional tons of rock. In addition it will be necessary to hoist waste rock in connection with development, but, as this will be mostly milled if taken from drives on the reef, a safe allowance would probably be say 300 tons a day. We thus have a total of say 2480 tons of rock to be hoisted from two shafts each working day, or twenty-six days per month. Consequently each engine must have capacity to raise 1240 tons in twenty-four hours. Even with 400 stamps, the total amount of rock would be only 1650 tons for each engine.

In this connection it is interesting to note some statistics of the Rand Mines, Ltd., showing the total cost of opening and equipping their properties. On a claim basis the average cost for nine companies is shown at £2846 per claim, and on a stamp basis £4253 per stamp. Multiply the area (600 claims) by the equipment cost per claim, and the cost of opening and equipment would be £1,707,600; and if £4253 be taken and multiplied by 400, almost the same figure is arrived at, viz., £1,701,200, showing that 600 claims for 400 stamps is the ratio in practical operation with the subsidiary companies of the Rand Mines, Ltd., at the present time. The fact, however, that with only 400 stamps the life of the mine from the commencement of milling would be some thirty-six years shows that, if possible, we should attempt to increase the output and make use of the reserve compartments and run 500 or 600 stamps.

I agree with Mr. Behr that, after reaching the reef, the only method to adopt is an independent equipment underground. The main incline shafts must have the same capacity for output as the vertical shafts; but on an angle of 27° a load of 17,621 pounds can be hauled with the same power as 8000 pounds in the vertical shaft. The weight of the rope is also taken up by pulleys on the incline, so that in the distance shown on the plan—5350 feet—the incline hoisting engines would only need to have power equivalent to hoisting 2429 feet in the vertical with the same factor of safety. In the arrangement for transferring ore from the incline to the vertical it will be noticed also that the main vertical shaft is across the formation. This allows of the most advantageous planning of the underground work when independent hoists are used, and the most disadvantageous method if it is desired to continue sinking from the surface on the incline, as well as from the vertical shafts, which system can only be advocated for moderate depths, and is utterly out of the question at 5500 feet.

If a depth of say 5500 feet can be reached in one stage, mining could be conducted to a depth of say 8000 feet by two sets of hoisting engines, one on the surface and the other un-

derground, hoisting on the incline. Mr. Behr's recommendations would require two winders on the surface for the vertical and one underground for the incline.

The Brownell Frue Vanner.

The Brownell Frue vanner, illustrated herewith, is claimed to be an improvement in durability, general construction and ease of manipulation over the regular machine, improvements being added, and some things which were a source of annoyance in the old vanner discarded, but all the desirable points of the Frue being retained. While a general description of the Brownell Frue vanner is not necessary some of the claims made for this concentrator, as illustrated, are that it is constructed entirely of iron, thus doing away with the cumbersome wooden frame; the side rails of the shaking frame are made of 3-inch channel iron, which are squared and held securely in position by tram or cross-rods; the 13-inch galvanized iron rolls that carry the main belt are beveled 3 inches back from the end, thus giving the roll a crown, and as the carriage frame is held perfectly square, the causes of the large belt traveling to one side are designed to be reduced to a minimum.

There is also introduced a new arrangement for stopping and starting the uphill travel of the main

carriage frame causes the end of the spring to wear the head of the drive-crank, so that after a few months the spring makes considerable noise. The drive spring, crank and collar have been discarded and an entirely new method of controlling the speed of the large belt has been introduced. Instead of a grooved pulley on the worm shaft a cone pulley is used, thereby enabling the attendant to increase or decrease the speed of the large belt by a slight movement of the hand wheel at the head of machine that controls the belt guide.

J. S. Brownell is the Western manager of the Frue Vanning Machine Co., room 15, 132 Market Street, San Francisco, Cal.

Large Traction Engine.

Herewith is illustrated a 110 H. P. traction engine recently built by the Best Manufacturing Co., San Leandro, Cal., for the Middle River Co. of Stockton, Cal., for use on the islands in the San Joaquin river where the soil is exceedingly soft. The drive wheels are 8 feet diameter, 5 feet face. The front or steering wheel is 50 inches wide, 64 inches diameter. Oil fuel is successfully used. The price of the machine is \$6500. Its special features are the great bearing surface of the carrying or drive wheels which enables

A 110-H. P. Traction Engine.

belt, accomplished by the slight movement of an eccentric in the hub of the worm-wheel guard, thereby disengaging the worm from the worm-wheel. The hangers that support the main and tightener rolls have double arms so that they are quickly placed in position.

The drive spring as used in the regular Frue has been a source of annoyance. The movement of the

it to go on ground and work successfully (although its weight is nearly twenty tons), where it would be almost impossible to drive a team of horses. It is particularly adapted to such soft sediment ground as that on the islands in the San Joaquin and Sacramento, Cal., rivers, where the soil is light and soft, and in the summer time so badly cracked that it is unsafe to work horses, and the dust so fine and light

The Brownell Frue Vanner.

in the dry season that neither man nor beast can stand it. It was necessary to build a dust-proof cab in the engine and use a blower operated by the engine to blow the dust out of the cab, so the engineer can breathe and see what he is doing. The Best Manufacturing Co. of San Leandro, Cal., report considerable demand for these engines.

The Stonewall Mine.

The Stonewall mine, in San Diego county, Cal., lies in a valley on the south side of a large artificial lake, called the Cuyamaca reservoir, near the summit of the Cuyamaca range. Pine and oak timber are abundant and the scenery is picturesque. The geological conditions under which the Stonewall mine is found finds a similarity in many regions of mica schist and mica slate. The veins are lenses of quartz occurring in the schist, usually disconnected, though often succeeding each other at short intervals for a considerable distance, and following along the same general strike. Sometimes these veins or lines of stress are accompanied by dikes, usually pigmatite or aplite. The quartz generally has a granular structure, with vitreous luster, and while such rock

Hoist and Shops, Stonewall Mine, San Diego County, Cal.

is usually condemned by prospectors as "unfavorable" to gold, yet quartz of this description is frequently very rich in gold. Mines of similar character are found in the Potter Ridge district of Madera county, Cal., in the southern Black Hills, South Dakota, in Canada, and in Georgia and the Carolinas.

In the vicinity of the Stonewall mine are large masses of norite, forming the highest peaks and ridges of the Cuyamaca mountains, extending many miles in a northerly and southerly direction. These rocks resemble the luster-mottled rocks of the Lake Superior region, but, so far as known, no mineral veins or deposits of value are found in them. The Stonewall mine, after an idleness of several years, is now being reopened. The accompanying illustration is that of the hoist. It has a 20-stamp mill and other machinery.

The Mesh of Wire Screens.

Written for the MINING AND SCIENTIFIC PRESS by
M. P. REYNOLDS.

It is generally understood by users of wire screens what is meant by the mesh of the screens—for instance, that 30-mesh has 30 openings to the lineal inch, or 900 openings to the square inch—but, unfortunately, the size of the wire used is not considered as seriously as it should be, although it really regulates the size of opening. This matter is of vital importance and a careful study of this point will reveal the fact that by varying the size of the wire it is possible to obtain the same size of hole in a number of meshes. The following will illustrate this feature:

STEEL WIRE CLOTH.

No. Meshes per Inch.	No. of Wire.	Decimal of Wire.	Size of Opening.
16	21	.032	.0305
18	23	.025	.0305
20	25	.020	.0300
22	29	.015	.0300
24	33	.011	.0300
26	36	.009	.0295

All of the above have practically the same size of opening, although there are six different meshes; therefore, it is the mesh and size of wire combined that must be taken into consideration when selecting screens to do a specified sizing.

All milling propositions are confronted with the question of screens, and in stamp batteries, jig

screens, trommels or mills of the Huntington type it is rather a complex problem, unless you have a list whereby a comparison can be made showing the various meshes with the respective sizes of wire in which they can be made and stating the size of the opening in each instance.

A catalogue issued by the W. S. Tyler Co., Cleveland, O., illustrates this feature, and a list taken from a page of the book is shown herewith:

IRON OR STEEL WIRE CLOTH.

No. Meshes per Inch.	No. of Wire.	Decimal Size of Wire.	Size of Opening.	Price per Sq. Ft.
23	27	.017	.0187	\$0.77
23	28	.016	.0197	0.65
23	29	.015	.0207	0.55
23	30	.014	.0217	0.46
23	31	.0135	.0222	0.35
23	32	.013	.0227	0.30
23	33	.011	.0247	0.26
23	34	.010	.0257	0.23
23	35	.0095	.0262	0.19
23	36	.009	.0267	0.17

30	28	.016	.0173	0.66
30	29	.015	.0183	0.56
30	30	.014	.0193	0.47
30	31	.0135	.0198	0.37
30	32	.013	.0203	0.31
30	33	.011	.0223	0.27
30	34	.010	.0233	0.23
30	35	.0095	.0238	0.20
30	36	.009	.0243	0.19

The efficiency of any screening apparatus depends upon the wise selection of the screens, and by keeping in mind the size of the opening, as shown in the above list, a screen can be chosen that will do sizing to the degree of fineness desired.

Another reason why this matter is important is because the heaviest wire can be selected that can be made to a given size of opening, thereby securing a screen that will be especially heavy and durable. Experimental runs are usually necessary to make a final decision as to which is the most efficient screen, but by considering the size of the opening feature and comparing the various sizes these experiments can be conducted intelligently and changes can be made from one size to another as the sizing of the screened product may direct.

Screens should be made with an even corrugation in both the warp and the shute wires, for screens of this character hold the mesh so firmly that the wires cannot shift from their original position, but screens which are made with the wires one way with a decided crimp, and the other way practically straight, are liable to cause endless trouble by the wires slipping out of place, rendering the screen worthless as far as even sizing is concerned.

The treatment of wire screens by the cold-rolled process according to recent experiments effectually prevents blinding or clogging, thus making it possible to increase the tonnage of a mill without increasing the crushing capacity. In trying out a scheme of this sort it is well to remember that it is false economy to secure the longest possible life of a screen and yet sacrifice the capacity in tons.

THERE are numerous isolated mining districts in the arid regions of the Southwest where the natural conditions are unfavorable to development and operation of mines, so long as the mine owners act singly, but these obstacles might be overcome if concerted action were taken to improve these conditions, in the way of obtaining water supply, providing good roads for cheaper transportation and securing milling facilities.

Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 10, 1903.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MINE CAR OPERATED DOOR.—No. 719,577; A. T. Flint and I. Whitney, Oskaloosa, Iowa.

Combination of mine door composed of upper and lower sections, upper section being hinged at top and lower section mounted independently of upper section and movable in opposite direction, whereby pressure of air on door will be equalized, and means for connecting sections to cause same to move in unison and for actuating sections.

PULVERIZING MACHINE.—No. 719,503; L. S. Pfouts, Canton, Ohio.

In pulverizing machine, rotating roll, oscillating jaw having portion extended below axis of jaw and located at one side of vertical axial plane of rotating roll, right-angled arms or extensions extending from oscillating jaw beyond vertical, axial plane of rotating roll, and pitman connected to free end of extended arm, and means for reciprocating pitman.

MAGNETIC SEPARATOR.—No. 720,156; J. Kirschweng, Butte, Mont.

A magnetic separator comprising chute, an electro-magnet, electric switch, swinging arm pivoted above chute, upper end of which is adapted to operate switch and lower end of which consists of separate piece hinged to upper end, and spring to hold lower end normally in alignment with upper end, arm being so arranged that its lower end may be actuated by accumulating material whereby when chute be-

comes choked circuit is closed to give alarm, alarm being absolutely continuous and without intermittence.

PROCESS OF RECOVERING AND SEPARATING METALS FROM THEIR ORES.—No. 720,235; H. A. Frasch, Hamilton, Canada.

Method of recovering copper and separating nickel and cobalt from matte or ore by electrolysis, which consists in providing system of electrolytic baths with soluble anodes composed of matte or ore to be treated, supplying anodes of any desired number of system of baths with solution of salt of alkali whose acid or halogen radical is capable of combining with metal represented in anodes, supplying cathodes with catholyte of different specific gravity, and regulating overflow of anolyte and catholyte by means of difference in specific gravity.

VENTILATOR FOR MINES.—No. 720,264; D. F. Lepley, Connellsville, Pa.

Drum having intersecting flues 7, 22, leading tangentially therefrom, common cutoff located at intersection of flues to close communication between drum and either of flues, by-pass connecting one of flues and intake of drum, by-pass having air opening and closure therefor, and valve to open or cut off communication between by-pass and flue with which it connects, in combination with revoluble fan or blower mounted eccentrically in drum, and closely approaching common cutoff, when the latter is in position to close communication between drum and flue 7.

STAMP MILL.—No. 720,054; W. S. McKinney, Chicago, Ill.

In stamp mill, combination of frame, stamp reciprocating therein, mortar carrying die in alignment

with stamp, wedge supporting mortar and comprising pair of blocks having oppositely inclined contacting faces, nut pivoted in each block, reversely threaded screw rod engaging nuts, and pair of links pivoted to frame and connected screw rod.

DRILL APPARATUS FOR DRILLING ROCK, MINING, ETC.—No. 720,319; W. A. Box and E. Y. Sayer, Denver, Colo.

In drilling apparatus, combination of guide frame adapted to be suitably held in position, drill shell or housing mounted to travel thereon and provided with instrumentality for giving travel to it, drill or tool, drill operating mechanism arranged within shell or housing, and mechanism for continuously rotating drill, housing having detachable portion provided with bearings for rotary parts of both drill operating mechanism and mechanism for rotating drill, principal parts of mechanisms being free to be drawn apart when detachable portion of housing is detached.

MINE CAGE.—No. 720,265; D. F. Lepley, Connellsville, Pa.

Combination with recessed guide timbers, of mine cage having main guiding members adapted for contact with opposite sides of guide timbers, tilting platform pivotally supported by guiding members, guide shoes carried by portion of platform structure at points above level of platform and adapted for contact with guide timbers at point intermediate length of main guiding members, shoes being adapted to pass through recessed portion of timbers on tilting movement of platform, inclined tracks supported at point adjacent to upper limit of movement of cage, and means carried by platform for engaging inclined tracks.

METHOD OF CONVERTING COPPER MATTE INTO METALLIC COPPER.—No. 719,488; G. Mitchell, Naco, Ariz.

Method of converting copper matte into metallic copper, by charging molten matte into acid or basic-lined converter and feeding practically pure silica in molten condition into molten matte while it is being blown to metallic copper.

COMBINED DUST CATCHER AND BLAST HEATER.—No. 720,257; W. E. Koch and J. W. MacDonald, Pittsburg, Pa.

In smelting plants, blast heater having oppositely located boxes connected by pipes, removable covers for boxes opposite ends of pipes, heating chamber containing boxes and pipes, and means for forcing blast through heating channels.

APPARATUS FOR HOISTING OR LOWERING MATERIAL.—No. 720,329; J. F. Cook, Johannesburg, Transvaal, South Africa.

In hoisting device combination of hoisting engine, hoisting ropes, skips or cars attached to ropes, tail ropes attached to skips or cars, other skips or cars attached to tail ropes whereby tail rope attached to one car acts as hoisting rope for another car, and means to receive load of car at highest point and transfer same to a car of next series when at lowest point.

CRUSHING MILL.—No. 720,480; H. U. Prindle, Sacramento, Cal.

Combination with holder for containing material to be crushed, frame detachably supportable over holder, frame having pendent brackets, and deflector plate M supported on brackets; of central shaft H, horizontally disposed carrier B, rotatable with shaft H, shaft G, journaled in carrier B, yoke E rotatable with shaft G, crusher rolls mounted on yoke E for independent rotation, and gear mechanism for joining shafts H and G, and imparting planetary motion to shaft G with its support E.

Mining Summary.

Specially compiled and reported for the
MINING AND SCIENTIFIC PRESS.

ALASKA.

(Special Correspondence) —The town of Nome is at present quiet. Everybody is busy on winter diggings. Dry creek benches are being worked extensively; also benches off Poluk creek. The Snowflake mine on Dexter is doing well. Fourteen men are working, a steam hoist has been erected and the manager expects to have a "dump" out before spring worth \$100,000. The Sugar mine at Dexter is also doing good work. The Surprise mine on Anvil creek is putting down a hole, prospecting. The Daisy mine is working six men. Last year this mine produced \$40,000.

There is a stampede to the Kongrook and Inmat huk river, the latter of which has proven to carry extensive gold-bearing gravels. Steam thawers are being employed in prospecting the ground. A number of thawers are busy on the Marine benches off Hastings creek, 9 miles east of Nome, where good diggings were found late this fall. Ophir creek benches are being worked. Work on Lane's ditch is suspended because of the short days, but will be commenced early in April. All available men will find work in Council before navigation opens.

The town of Nome is healthy and growing. Provisions are moderately high, with the exception of coal at \$35 per ton and eggs at \$20 per case, ham at 20 cents per pound and bread at 10 cents per loaf. Nome, Nov. 26, 1902.

Two thousand miners are reported stampeding to Tanana from Nome, Dawson, Eagle and Rampart. U. S. Commissioner Claypool writes from Circle that 600 claims have been recorded in the new district, which is known as Fairbanks. Fifty three creeks have been staked.

T. H. Ellis, president and manager of the Yellow Jacket M. Co., on Windham bay, near Juneau, says they will double the capacity of their milling plant installed last season, and will handle 100 tons of ore per day.

ARIZONA.

COCHISE COUNTY.

The Bisbee, Arizona, G. & C. M. Co. has been organized to operate in the Warren mining district, northwest of Bisbee. M. D. Scribner, C. T. Clark, J. Schmidt, F. H. Bopp are the officers.

The Leadville M. Co. has incorporated to operate the consolidated Holmes, Fitch and Storebeck groups near Gleason. The officers are: W. Holmes, C. M. McKean, H. T. Fitch, W. A. Sorebeck and H. A. Morgan. The ores carry copper values.

GRAHAM COUNTY.

The Shannon Copper Co. is building a railroad from the Wiseman tunnel to the Antietam mine, near Metcalf. Their smelter will resume next week.

Superintendent Melder of the Home Copper Co., near Clifton, says they have opened a body of \$70 gold ore on one of the company's claims.

MARICOPA COUNTY.

Superintendent Franklin is building a road from the Wickenburg-Gilbert road, near Wickenburg, to the shaft on the Uncle Sam C. Co.'s mine, after which the shaft, down 100 feet, will be retimbered and a gasoline hoist installed and sinking continued to the 500-foot level.

MOHAVE COUNTY.

C. Hoffman of Enterprise, Kan., one of the owners of the Samoa and Fourth of March mines, near Chloride, has bought the Paymaster mine near Cerbat. Work will begin next week.

The Mohave G. M. Co. will build a 40-stamp mill, near Mellen, out from Kingman.

The Railroad mine, near the Gold Road mine near Kingman, has been sold to the Gold Road Co., A. Chapelle, manager, for \$10,000. The mine is the south extension of the Gold Road.

S. C. Bagg, general manager of the New Comstock mines, near Kingman, says machinery for development work will be put in at the Katherine mine of the group and a mill and reduction plant installed.

At Bull's Head canyon, 2 miles below the New Comstock mines, on the Colorado river, the Government is using a diamond drill boring holes into the river bed. The first 40 feet was through sand and gravel and the next 15 feet was in granite, that will make a secure foundation for the dam contemplated at that place. There are, approximately, 50,000 acres of land that can be brought under cultivation below the dam and above the Needles. It is reported electric power will be generated and sold to mining companies operating in that vicinity. All

the land to be benefited has been temporarily withdrawn from entry.

The Revonue M. Co., with mines near Ehrenburg, reports returns on a carload of ore shipped to the Selby Smelting Works, San Francisco, Cal.: Gold, 114 ounce per ton; silver, \$3.30 ounces per ton; copper, 32%.

Fourteen inches of ore is reported in the main tunnel on the back vein south at the Samoa mine. The ore carries shipping values in gold, silver and lead.

PINAL COUNTY.

Manager A. T. Colton drove a crosscut at the bottom of the Marion shaft last week to determine the width of the Marion vein, 30 feet below the surface, and shows the vein 18 feet wide, with a 3 foot pay streak of copper ore on the hanging wall. The mine is in the Red Hills, 12 miles east of Florence.

The Dragoon Con. M. & S. Co. at Pearce, in the Dragoon mountains, has its shaft down 100 feet. A gallow's-frame is being built and a 34 H. P. gasoline hoist will be installed. A millsite with water rights has been secured and a smelter is under consideration. There are twenty claims in the group.

It is reported at the Troy-Manhattan copper mine at Troy that a body of copper sulphide ore has been opened up, carrying good values in copper and gold. A sixty-ton smelter is turning out four tons of copper a day. The company has 1200 acres and is pushing development work at the Stinson, the Alice and Buckeye. Stopping ground has been opened in the Buckeye on high-grade ore. The management contemplate putting up a larger smelting plant within a few months.

YAVAPAI COUNTY.

(Special Correspondence) —Hot Number tunnel, in the Bradshaw mountains, owned and operated by the Copper Cobre M. Co., is in 900 feet. When completed it will be 2500 feet. It is 9 feet wide, 8 feet high, with double tracks. Progress, 225 feet monthly, using power drills. The power plant is $\frac{1}{4}$ of a mile from the tunnel. The Ironclad tunnel is in 500 feet, and will drive to 2500 feet. Veins occur in a zone 3000 feet wide. This company owns a strip 6 miles long and 314 miles wide. The ore carries copper, gold and silver. G. W. Middleton of Prescott is manager.

The French Lily mine is down to the 200 level and taking out shipping ore. They have a 20-foot vein.

Prescott, Feb. 11.

(Special Correspondence) —The Knickerbocker G. M. Co. of Prescott is working the Hidden Treasure mine, 4 miles from Turkey Creek station, on the P. & E. Ry.; four shafts on the property; cleaning and retimbering shafts. Drifts connect shafts Nos. 1 and 2 at the 50 and 90-foot levels. The drift from shaft No. 3 shows a body of good ore. Will sink shaft No. 1 to the 600 level and will put in a hoisting plant and 10-stamp mill. The water will be supplied from Dripping springs, 4 miles distant, to which a pipe line will be laid. The mine is in Black Canyon mining district. E. S. Campbell, of Prescott, is manager.

E. A. Franke, of Turkey Creek, is operating his 2 stamp mill on his property in Black Canyon district.

Turkey Creek, Feb. 11.

(Special Correspondence) —The Iron King mine, owned and operated by the American Copper Co., is about $\frac{1}{2}$ mile west of the smelter at Val Verde. They have twenty claims. The main working shaft is down 260 feet. The first level is at 133 feet. There is a drift running south 400 feet connecting with another shaft and a drift running north from the main shaft 400 feet. No. 2 is the main shaft. From shaft No. 1 there is a drift over 200 feet. There are three crosscuts on this vein about 300 feet apart. All the shafts, drifts and crosscuts are in ore. At present about fifty men are working. A 200-ton concentrating and cyanide plant is now being erected. The mill is being built by the Joshua Hendy Machine Works of San Francisco, Cal. They expect to have the mill in operation by March 20th. B. Blanchard is general manager.

Val Verde, Feb. 11.

(Special Correspondence) —At McCabe the Model G. M. Co. has ordered machinery for increasing the mill capacity, now ten stamps, and also for handling the dump at the mine and mill. The ore in the dump contains payable values. The main shaft is down 700 feet and will be sunk 200 feet farther. They have finished retimbering the shaft destroyed by fire between the third and fourth levels. There are several thousand feet of tunnel and drift work in the mine. Ore is shipped to the smelter at Val Verde. L. W. Felt is manager.

The Henrietta mines, six claim, was bought by the Braganza G. M. Co. a year ago. P. A. Johns, manager, has been developing the mine and repairing the

mill, which had been idle for a number of years. The tunnel is in 2000 feet, connecting with the main shaft, 300 feet deep. Levels connect shafts Nos. 1 and 2 at the 200 and 300 levels; 4000 feet of work has been done. They have several dwellings, an office, assay office, mill and boarding house, and are erecting others. The mine is on the McCabe side of the hill and the mill is at Big Bug. They are putting in a tramway from the tunnel to the mill. The ore has been packed on mules over the mountains. The company has been running ten stamps and is now putting in ten more. The railroad crosses the property. The water supply is pumped from a well in Big Bug creek, 800 feet distant from the mill. Sixty men are employed.

McCabe, Feb. 16.

C. T. George has bought a group of claims at Poland, in the Poland district, near Prescott, and made the first payment of \$16,000.

The number of men working at the smelter of the United Verde at Jerome is being increased. The 500, 600 and 700-foot levels are being opened up from the new shaft. Three of the small furnaces are in operation and a fourth ready to be blown in. The 500-ton furnace will be finished next week.

YUMA COUNTY.

At the Valenzuela group, near Quartzite, drifting has been started on the 216-foot level. The shaft has been sunk to that depth on the vein, with only one wall showing. No. 3 shaft will resume sinking.

The Harqua Hala M. & M. Co. of Philadelphia, Pa., men have bought the Mineral Belt group of claims near Yuma for \$150,000.

CALIFORNIA.

AMADOR COUNTY.

(Special Correspondence) —On Sutter creek, beginning about $\frac{1}{2}$ mile above the town and extending for a mile or more up the stream, the bed of the creek has only partially been worked for gold. The past year extensive preparations have been making to recover the gold in the channel. A long drain ditch has been dug and a large number of men will be employed in sluicing this ground this spring. A mile above this place a second company is at work under direction of Superintendent Clough engaged in similar work.

The reports that the Ballou mine, near Sutter Creek, is about to resume operations is not true, no such move being contemplated at present.

The Oneida mine shaft has been sunk to the limit of the hoisting reel, without remodeling the same. There is abundant capacity in the engine, but the reel will not hold more rope without extending the arms which guide the flat rope to its position.

Sutter Creek, Feb. 18.

At the Zella mine, at Jackson, the shaft repairs are completed and operations will resume this week. The chlorination works have exhausted the supply of sulphurets on hand and are closed down temporarily, says Superintendent W. F. Detert.

The stoppage of the power plant at Electra resulted in a suspension of the mill and underground operations, except shaft work at the Oneida mine, near Jackson. This mill is entirely dependent on electric power. The shaft sinking will be finished next week.

F. Glanville of Drytown, with F. Cupp, sluiced out \$350 worth of gold in the hotel lot the last two months, says the Ledger. The nuggets found range from \$3 to \$9. Last week, on reaching bedrock, he struck a quartz vein 4 inches thick carrying free gold, which he will develop.

Owing to damages done the pipe line of the Standard Electric Co., above Electra, by the storm, several of the quartz mills have been idle in this county the past week. The Central Eureka mine, near Sutter Creek, is obtaining power temporarily from Marysville.

CALAVERAS COUNTY.

The twenty stamps at the Sultana mine, near Angels, are in operation, says Manager Morgan.

S. P. Smith will start work on the A. P. A. and Boston Consolidated mines, near Angels, and as soon as the weather will permit a 10 stamp mill will be erected.

It is reported at Angels that the Morgan mine on Carson hill, 5 miles south of Angels, is soon to be reopened under the direction of the heirs of J. G. Fair. The property, which has the reputation of being rich, has been in litigation for many years.

The Mountain King G. M. Co. has bought the Heinsdorff group, between San Domingo creek and Indian creek, near Murphys, including the Rose Rock mine.

The Carson Hill G. M. Co., near Irvine, has begun work on a 10-stamp mill, says W. Smith. Two shifts are at work in the 700-foot tunnel being run for the ore shoot.

The tunnel of the Jack Rabbit mine,

near Angels, in 425 feet, will be driven ahead 200 feet, says Superintendent F. Purinton.

At the Oriolo mine, near Angels, the 10-stamp mill is in operation and ten stamps more will be put in this spring, says Superintendent E. D. Griffith.

The Why Not quartz mine in Chili gulch, near the Quaker City mine, 3 miles southwest of Mokelumne Hill, has resumed operations under Superintendent J. E. King.

The Phillips gravel mine at Buckeye, owned by T. C. Peters of Mokelumne Hill, will be worked by a company, with W. T. Robinson, superintendent, says the Chronicle.

The gravel mines of Sloan & Rudoff Bros., at Balaklava Hill, near Vallecito, are under bond to A. Lunberg for two years for \$15,000.

EL DORADO COUNTY.

W. A. Witherspoon of Colorado and D. Boscut of Placerville have bonded the Gray mine, near Shingle Springs.

The Montezuma M. Co. at Nashville has put in a new double hoist. The machinery was removed from the Mutual mine, near Sutter Creek, in Amador county.

KERN COUNTY.

W. S. Morton, president of the Potomac Oil Co., in Kern River field, near Bakersfield, will drill two additional wells. There are eight wells on the lease and the company has, with its Summerland and Los Angeles product, a daily output of 500 barrels — The Monarch Oil Co., near Bakersfield, and its lessees, will put down ten new wells.

The Union Oil Co. is putting down twelve additional wells on the Claremont lease in the Kern River district, near Bakersfield.

The Sedala & California well, No. 5, at Sunset, is producing 600 barrels a day, according to reservoir measurement, says the Californian.

Well No. 1 of the Twenty Oil Co., near Bakersfield, was started pumping last week. The casing in No. 2 has been perforated.

The Belgium Oil Co. at McKittrick is pumping two wells which are yielding 300 barrels a day. The company has sold its output to the extent of 25,000 barrels and more wells will be drilled. The company has its own pipe line, 3 miles in length, and sixty acres of land.

A. S. Munson of Colorado Springs, Colo., secretary and treasurer of the Federal Crude Oil Co. and the Sunset Asphalt Refining Co., says work will begin by March 1 on their refinery to be built at Sunset to handle the product of the Federal Co., which is a consolidation of the Colorado-California Fuel Oil Co. and the Wichita Oil Co.

The Exposed Treasure M. Co., near Mojave, P. Humbert Jr. manager, is operating a 20-stamp mill. Water is supplied through a 15-mile pipe line.

MONTEREY COUNTY.

President Brophy of the Combined Oil Land Co., says they are drilling a 14 inch well on their ground, 6 miles south of San Lucas.

NEVADA COUNTY.

(Special Correspondence) —It is reported that the Idaho-Maryland mine, near Grass Valley, is to be reopened by a Boston company, who will begin unwatering the mine. It has been closed down since 1901. The mine has been worked to a depth of over 2000 feet on the ore shoot, which extends through three mines, beginning at the surface in the Eureka and dipping downward through the Idaho into the Maryland. Crosscuts run in the bottom levels indicate that there are parallel ore shoots in the foot wall. The mine is equipped with large hoisting works, 40 stamp mill, compressors, etc. It is stated that the ore shoot has produced in the three mines \$25,000,000 in gold. The new company will be known as the Idaho-Maryland Development Co., with its office at 101 Milk street, Boston. The officers are T. W. Shapleigh, E. M. Preston, G. E. Marvin, H. P. Colson, C. B. Lakenan, at present superintendent of the Coe mine, near Grass Valley, will be superintendent of the new company. The company will enlarge the works and will install modern machinery.

ORANGE COUNTY.

The Fullerton Tribune says thirty-four new wells are being drilled in the Fullerton field and three rigs are in course of construction.

W. B. McPherson, superintendent the Santa Ana tin mines, in Trabuco canyon, 30 miles southeast of Santa Ana and 15 east of El Toro, on the Santa Fe railroad, says the mill will be increased to fifty stamps and other machinery installed. J. A. Comer of Los Angeles is manager.

SACRAMENTO COUNTY.

Superintendent L. Wing is putting in

machinery at the mine of the Sacramento & Rescue M. Co. at Blue ravine.

SANTA CLARA COUNTY.

Manager R. B. Harper of the Santa Teresa Q. M. Co., operating the Santa Teresa quicksilver mines, 10 miles southwest of San Jose, says development work will be increased and a furnace with 30-ton daily capacity built. A second furnace will be erected later in the year. Men are driving new tunnels and cutting a road from the mine to the main county road.

SHASTA COUNTY.

The resumption of work at the Keswick smelter has caused a renewal of operations in the mines east of the river. At the Central mine, in Old Diggings district, the number of men at work has been increased to twenty-five. The shipment of ore to the smelter begins this week. The railway from the mine to Central spur has been repaired, the ore from the spur being sent across the river by an aerial tram and dumped at the smelter. The Texas mine has taken on more men and shipments of ore to the Keswick smelter begun. Other smaller properties will resume shipments.

The J. J. Chambers Co. of Redding has bonded the Mabel, Emma and Vulcan group of mines on Mule mountain. The Free Press says the property will be taken up by the Great Divide Gold Co. Work will begin next week on the stamp mill for the Great Divide and will be set up on Clear creek, convenient to all the mines of the group, including the Gold Dollar and Cardiff.

SIERRA COUNTY.

The Sierra Butte mine, near Sierra City, has resumed operations and the forty men who went on strike have gone back to work.

SONOMA COUNTY.

The Healdsburg Quicksilver M. Co. has incorporated; directors, G. H. McCullen, J. C. Hobson, F. A. Cruse, C. D. Evans, W. B. Whitney, J. Wilson and W. B. Kruse of Healdsburg. The company will operate in northern Sonoma county.

TRINITY COUNTY.

G. H. Gill, having a bond on the Yellowstone mine, on the east fork of the north fork of Trinity river, near Coleridge, will reopen the mine. There are 2000 feet of underground work on two of the claims, showing a 5 foot rim. The mine is equipped with a 10-stamp mill and 800-foot tramway.

TUOLUMNE COUNTY.

J. P. E. Heintz of San Francisco has bought the Leland ranch pocket mines on Nigger hill, near Jamestown, and will begin development.

The Harvard mill, near Jamestown, is dropping forty stamps, says Superintendent Gorrie. The 20-drill air compressor is in operation, the underground connections being completed. The use of No. 2 shaft for hoisting purposes is discontinued. A station pump is being put in on the 700 level.

The App shaft, near Jamestown, says Superintendent W. L. Turner, will be sunk 200 feet below the eleventh station. W. A. Nevills, the owner, says he will install a cyanide plant in Quartz, as 300 tons of sulphurets per month are being treated at the two chlorination plants at the Rawhide.

Work will soon begin on the power plant projected by Sidney Sprout, E. E., of San Francisco, Cal., and others on the Tuolumne river. It is estimated 2000 H. P. will be generated.

At the Mt. Jefferson mine at Groveland an overhauling of the mill is in progress, says Superintendent J. H. Gilmore. New foundations, mortar blocks, etc., will be put in.

The New Era says the Superior Court has given judgment for J. E. Conde of Carters against the Dreisam G. M. & M. Co. on the foreclosure suit of the Dreisam gold mine, above Carters. The judgment was for \$9000.

Articles of incorporation of the Mount Jefferson Mines, Con., have been filed. The company was formed under Arizona laws, with Phoenix as headquarters. The mines are near Groveland. J. M. Melghan, C. H. Hilbert, C. F. Humphrey and B. Goodwin are directors, and J. H. Gilmore superintendent.

The double compartment shaft of the Sierra, near Groveland, is down 110 feet. The tunnel has cut the vein at a depth of 70 feet, and drifting has developed 10 feet of ore assaying \$39.

At the Spring Gulch or Marshall mine, south of Carters, in a drift from the 700-foot level a vein has been cut that crosses the Spring Gulch vein. It is 2 feet wide and shows free gold. The mill will resume next week.

The Providence mine, near Carters, has resumed after repairing the hoist. Drifts are being run on the 1000-foot level.

At the Soulsby mine, at Soulsbyville,

they are sinking a winze on the 200 level on the shoot, and running the 300 level to connect with this winze. The vein is 12 inches wide and shows free gold. The mill is running one shift, ten stamps, says Superintendent W. Sharwood.

At the Mountain Belle the water power hoist is in operation, with 200 feet pressure from the ditch, which carries the water to the Soulsby and Black Oak mines. At the 100 level drifts are being run.

COLORADO.

A report from Denver says the State of Colorado has begun quo warranto proceedings against the American S. & R. Co. for the annulment of its charter and to prevent its further operating in that State unless it pays its taxes. This action, it is said, will test the validity of the flat tax law.

ARAPAHOE COUNTY.

A \$15,000,000 steel plant will be one of the results of the building of the Moffat road to Routt county and Salt Lake City. The Frontier Coal & Steel Co. has incorporated—D. H. Moffat, C. J. Hughes Jr. and W. G. Evans—and will build steel works near Denver. "We have 20,000 acres of land from which a site may be selected, convenient to the city and near the line of the new road," says D. H. Moffat.

BOULDER COUNTY.

The Wisconsin Oil Co., subleasing from the Boulder Oil Co., has opened a flow of oil at a depth of 2060 feet in its new well at Boulder.

The Longfellow mine at Jamestown has been sold to the New Century M. & M. Co., of which R. G. Munn is manager, for \$200,000. The mine has free gold and telluride ores.

The Copper Ranch at Sunset is developing its properties, comprising 170 acres. The main development is on the Kate vein, where a shaft is sunk on the vein at a dip of 30° from the vertical. It is 217 feet deep. The vein varies from 8 inches to 3 feet in width. Through this occurs a pay streak of heavy sulphide varying in width from 4 inches to 1 foot. Samples show values of \$8.70 to \$61.20 per ton in gold.

Eubanks, Jump et al., operating claims in Long's gulch, have opened up several veins of low-grade ore, some of them being 10 feet in width. The claims are so situated that a crosscut tunnel will open all five of the claims at good depth. The crosscut tunnel, which has its portal on the White Star vein, has been driven 125 feet.

Fifteen men are leasing on the Big Five mine at Francis and they expect to ship five cars weekly to the Wall Street mill. They have built a side track from the Big Five switch to the tunnel so that cars can be beloaded at the mouth of the tunnel directly from the tram car.

Manager H. B. Neff at the Valley Forge mine, above Salina, has the ore bins full awaiting shipment of three cars of low-grade ore to the Wall Street mill. Work has begun on a new slope 300 feet from the face of the tunnel.

R. Wiggers of Gold Hill, operating the Small Hope group in Wilson gulch, has opened up a body of low-grade ore. The property is a tunnel proposition and has been developed for 250 feet. The ore runs from \$15 to \$18 per ton and he has made one shipment of forty tons to Wall Street.

CHAFFEE COUNTY.

A bond and lease on the Gold Bub mine, near Turret, has been given to the Gold Pan M. Co. of Victor, and development work will begin next week.

The Gold Bug mine, at Turret, has been bonded and leased by the Gold Far M. Co., operating at Victor, Colo., and Mercur, Utah.

CLEAR CREEK COUNTY.

Superintendent M. Tong of the Aliunde mine, on Leavenworth mountain, near Georgetown, says 17,900 ounces of silver was the product of three men's work during a part of January. The ore was taken from the Haggart lease on the 1000-foot level.

E. W. Williams of Denver, operating the Specie Payment mine at Idaho Springs, says drifting is under way on both sides of the shaft, and a new ore body found on the west side showing smelting and milling ore. The mill bought by this company will be rebuilt.

The Shafter mine, near Idaho Springs, is arranging to lease the Allen mill, says Manager Roller. Drifts extended at the fifth and seventh levels have opened 5 feet of concentrating ore, and raises are being driven connecting the lower levels.

There are forty sets of leasers working in the Franklin mine, near Idaho Springs, on ore bodies opened up by the Franklin Co., which is consolidated with the Freighter's Friend.

G. B. Holden of Boston, Mass., managing director of the Silver Mountain M.

Co., at Empire, says the mine will be reopened and the mill put in operation.

It is reported the Stanley mine, owned by the Stanley Con. M. Co., near Idaho Springs, has been sold to A. D. Bulls at sheriff's sale on a judgment of \$34,000.

CUSTER COUNTY.

W. B. Jackson, operating the Webster group of mines, near Silver Plume, says a 500-ton chlorination plant will be installed.

DOLORES COUNTY.

The Mt. Gorum M. & M. Co., at Dunton, is crushing twenty-five tons of ore per day in its 10-stamp mill, producing one ton of concentrates. A carload of concentrates was shipped to the smelter this week. The company has thirty-seven men at work. The tunnel is in 600 feet, and 500 feet of it is stopping ground. The values are principally in gold.

EL PASO COUNTY.

At Colorado City 150 members of the Mill and Smelterman's Union, employed in the Standard smelter of the United States R. & R. Co., are reported to be out on a strike, due to a question of wages.

FREMONT COUNTY.

The Canon City smelter of the United States R. & R. Co., south of Canon City, is to be further enlarged this spring, the recent increase in capacity proving inadequate, says the Denver Times.

The factory of the Colorado Portland Cement Co., 6 miles east of Florence, is closed indefinitely, says Superintendent A. Moore, as the larger plant of the company can readily supply the 300,000 barrels of cement, the estimated annual consumption of Colorado.

GILPIN COUNTY.

Manager B. W. Myers reports an 8-foot body of ore struck on the Hall ranch property of the Fostoria G. M. Co., operating in Pleasant Valley district, southeast of Central City. The strike was made in the Summit shaft at a depth of 127 feet, and shows milling ore.

The shipments from Gilpin county for January show an increase in the shipment of ore and concentrates from Black Hawk. During the month 367 cars of ore (7340 tons), were shipped, an increase of 50 cars over January, 1902.

At the Running Lode mine, below Black Hawk, operated by the Gower Mine Syndicate, Limited, of London, England, they are taking out 450 tons of ore per month, which is netting \$7000.

On Michigan Mountain, near Apex, the Cow Boy group, owned by the Stuart, Murray & King Co. of Denver, is being developed. A tunnel following the vein is being driven from Silver creek to cut the old workings at greater depth.

Boston men have an option on the Two-Forty mine, near Russell Gulch, and are forming a company to operate the same. Machinery will be installed and development carried out through the 80-foot shaft near the upper tunnel working, but which will be sunk several hundred feet.

A local company has taken a lease on the I. X. L. claim on Pewabic mountain, near Central City, and is erecting a small shaft building for temporary purposes. The shaft is down 100 feet, showing smelting ore.

For the first week in February the ore shipments and tailings sent from the Black Hawk depot were seventy-one cars, or 1420 tons. On account of a shutdown at the Golden smelter for two weeks, the shipments for this month can hardly be expected to show their customary increase.

The Russell Gulch M. & D. Co., in which Idaho Springs men are interested, has decided to install machinery on the Rocky Mountain Terror, near Russell gulch, on which it has a lease and option, and expects to begin development next month.

GUNNISON COUNTY.

The Gold Pick group, near Vulcan, is being operated by the Gold Pick M. Co., recently incorporated by local and Nebraska men. On the Arabella at Vulcan at 100 feet the operators are opening up a vein of copper ore, some of which has been stooped out.

The Headlight M. Co. at Spencer last week installed a pumping plant on its shaft. The shaft is down 125 feet and will continue sinking before running a level. The mine is owned by the Christian Moerlein B. Co. of Cincinnati, Ohio.

In the Dandy mine, near Spencer, owned by F. Holt of Spencer, with D. F. Strouse and J. T. Phillips of Gunnison, while working in the 50-foot level last week, the operators cut 5 feet of ore and drifted on same, which runs \$15 in gold per ton. In the bottom of the shaft a shoot streak of ore is showing, which carries tellurides.

HINSDALE COUNTY.

T. C. Malone of Paterson, N. J., will reopen the Union Pacific mine in Alpine gulch, near Lake City.

H. F. Wells, secretary of the Henson

Creek Lead M. Co., says they have closed down their mines near Lake City until spring.

LAKE COUNTY.

Manager Newell the Fryer Hill Mines Co., at Leadville, says the Pride of the West shaft will be sunk 400 feet, at which depth it is expected the Cady ore body will be cut. The Yak tunnel, near Leadville, is within 150 feet of the Ibox No. 4 shaft, the line of which it will cut at 200 feet below the bottom, and a drill hole is being sunk so that the shaft may be sunk to the tunnel level without trouble from water. The sulphide mill of the Arkansas Valley smelter is expected to be in operation by Feb. 24. It will have a capacity of 300 tons a day. The Bon Air, near Leadville, has increased its shipments of iron to fifty tons per day.

Director H. R. Morris of New Milford, Pa., and Manager J. Guth, are examining the Banker mine, near Leadville, with the intention of installing a reduction plant to handle their low-grade ore.

The Midas M. Co. at Leadville has bought the mines and equipment of the Coronado and Phoenix companies in the oxidized iron belt of Leadville basin. They now control the Midas, Coronado, Sixth Street and New Northern groups.

The last named gives them iron-silver bearing ground, extending beyond Ninth street into Poverty flat. The central pump station for the present will be the Coronado shaft, which is 650 feet deep. The shaft will be drained, a station cut, and 600-foot drift run to connect with the Midas shaft 110 feet below its bottom. A drift of 600 feet will connect the 650-foot level of the Coronado with the Sixth Street. Superintendent D. Jones expects to have these connections made by May 1. In the meantime shipments will continue from the Midas and Phoenix upper levels. S. D. Nicholson is manager.

The Yak tunnel near Leadville is within 150 feet of the Ibox No. 4 shaft. It is not intended that the tunnel shall cut directly beneath the shaft, but 30 feet distant, and a crosscut will be driven, when the 4-inch drill hole now going down from the No. 4 will be cut, says Engineer H. Platt. The Best Friend tunnel is in 250 feet, and by April 1st it is expected to get under the old shaft where the vein should be cut.

LARIMER COUNTY.

The Pearl C. M. & S. Co. was incorporated last week to operate near Pearl. W. L. Culbertson, W. A. McLogan, C. Mark, R. E. Coburn and P. B. Coolidge.

LAS ANIMAS COUNTY.

The Northern Coal & Coke Co. is opening up a mine in Timber canyon, a few miles north of Trinidad, with G. Fruth as superintendent.

Development work is being done in the Green Canon mine, near Aguilar, with J. R. Bond as superintendent.

MINERAL COUNTY.

The Humphreys mill, near Amethyst, will be started up next week, says Manager Fitzgerald.

OURAY COUNTY.

A strike is reported in the Newsboy mine, near Ouray, owned by the Newsboy Co. of Colorado Springs, showing a body of high-grade ore uncovered near the breast of the 1600-foot tunnel. Shipments will be made to the Denver smelters, while the second grade is being stored to await the erection of a company mill, which will go up this spring.

The Treasury tunnel at Red Mountain, near Ouray, closed down last week. The tunnel is in 4000 feet. Manager W. J. Hammond, Jr., says the company has been having litigation in its efforts to get a right of way, and many attempts have been made to stop the driving of the tunnel by injunction.

PARK COUNTY.

The Badger Mountain M. & M. Co. has been incorporated at Colorado Springs to operate a group of six claims in the Badger Mountain mining district. M. L. & J. H. Crasper, H. J. Newman, G. O. Beal and W. G. Newman are the officers.

PITKIN COUNTY.

Men are at work overhauling the Mollie A. mill, near Aspen, to handle the ore from the Newman tunnel dump. The railroad will build a switch to the dump. It is estimated that there are 30,000 tons of ore in the dump, which will net the mine \$3 a ton profit.

SAN JUAN COUNTY.

In the quarterly report of the Kendrick & Gelder S. Co., Superintendent Umbell of the Henrietta mine, near Silverton, says 2000 feet of work have been completed on No. 7 level, 600 feet on the vein. No. 10 level is being driven to cut the Orloff, Surprise and Henrietta veins 300 feet deeper. E. W. Walter, superintendent of the smelter, says a profit is made from

the fractional quantities of gold (less than \$1 in gold per ton not being paid for), and from the fact that the loss in smelting silver does not equal the percentage deducted on that account. The shipments for the season show that 9.9 tons of crude ore is concentrated into one ton of matte.

SAN MIGUEL COUNTY.

F. J. Hobbs of the Butterfly mine at Ophir, says in the lower tunnel the Ida ore shoot has been opened up for 300 feet, showing a continuous ore body. There are 2 feet of milling ore exposed in the breast of the workings. The Butterfly-Terrible Co. is operating fifteen stamps.

TELLER COUNTY.

Repairs are being made on the St. Patrick shaft house which was partially destroyed by fire last week. The extent of the damage done amounted to \$1000.

The weekly statement on shipments from Stratton's Independence mine at Cripple Creek, issued from the London office, shows the following output for the third week in January: Jan. 17, 255 tons, £950; 18, 255, £950; 19, 230, £800; 20, 230, £800; 21, 260, £950; 22, 240, £600; 23, 215, £700.

Manager S. Bell says sinking will be resumed on the Hull City placer, near Cripple Creek, by the Cripple Creek M. Co., operating the ground under lease. The shaft is down 1150 feet. It is expected the total production for February will reach 2000 tons of an average grade of \$35.

The directors of the Mary Nevins Co. last week granted a lease on the north end of the Nevins & Hibernia group, near Cripple Creek, to Cree, Bowers & Lewis, of Colorado Springs. The shaft will be sunk to 300 feet. The remainder of the property will be leased.

Operations have been resumed by the Lansing Leasing Co. on the Pinnacle mine, on the north slope of Bull hill, Cripple Creek.

Operations are resumed on the Pauper mine at Cripple Creek by Practical G. M. & L. Co. J. A. McIlwee is superintendent.

Nesbitt & Miller are installing a cyanide mill on Bull hill, Cripple Creek, to treat the dump of the Pharmacist mine, and expect to begin operations this week.

The directors of the Forepaugh G. M. Co. have granted a lease on the north 400 feet of their ground on Squaw mountain, adjoining the Alhambra, near Cripple Creek, to Dray & Co. for two years at 20% royalties.

Thirty feet a day are being made in driving the El Paso drainage tunnel, Cripple Creek, as follows: Ten feet a day from the portal, 10 feet south from the El Paso shaft at 600 feet, and 5 feet each way from the intermediate shaft in Aequa gulch. It is 960 feet from the portal to the first working shaft, and 300 feet of this has been driven. The bulk of the work lies between the El Paso shaft and the second or deeper working shaft which is being sunk on the Republic ground at the rate of 5 feet a day.

Lessee Hummer, operating through the Sweet shaft of the Gold Bond Co. on Gold hill, Cripple Creek district, is shipping 100 tons of ore per month that averages \$40 per ton in gold.

Manager De la Vergne of the Isabella mine, at Cripple Creek, says new shoots have been opened in the ninth, tenth and eleventh levels. This vein has been found east of the Buena Vista, and in the ninth has been proven for 100 feet. The screenings run two ounces gold. In the tenth and eleventh levels another vein has been found, which gives values of \$25.

The Valley City Leasing Co., holding a bond on the Shurtliff No. 2, Cripple Creek, ceased sinking and have begun cutting a station at the 900-foot level. Shipments from the upper levels will be resumed.

H. F. Hossman of Cripple Creek has a one year's lease on a block of the Trail mine below the lower tunnel level, and begun development work.

E. M. Crockerly, who has been leasing on the Gold Dollar dump, has had his lease renewed and will put in machinery to handle the waste rock on a larger scale.

F. Duncan of Cameron has bought an interest in the Robertson Bros. lease on the Flying Cloud, near Cripple Creek, and more men will be put to work.

G. F. Fry, manager of one of the Cripple Creek samplers, says there isn't a sampler in the district that is not receiving as much ore as it can handle. When the drainage tunnel is completed such mines as the Mary McKinney, Anaconda, Elkton, El Paso, Doctor-Jack Pot and others will be able to ship double the quantity of ore they are now sending out.

IDAHO.

BOISE COUNTY.

The Edna mine, 22 miles from Idaho City, has closed down until March 15, owing to the heavy snow.

IDAHO COUNTY.

The mill of the Gold Coin M. Co., Black Lake district, near Weiser, is in operation. W. H. Davis is superintendent.

The Homes'ake and Idaho groups, near Thunder, of seventeen claims on Beaver creek, adjoining the Wordenhoff mines, have been sold to H. L. Hollister of Chicago, for \$125,000.

The 5-stamp mill of the Galena Creek G. M. & M. Co., near the American Eagle group, near Elk City, is in operation, says Manager J. D. Boyer.

P. R. Hogan of West Superior, Wis., part owner of the Hogan mines at the Grande, on Crooked river, near Elk City, says more stamps will be added to their mill in the spring.

The American Eagle M. Co., operating near Elk City, has received \$7544.22, as the result of the first month's run on 600 tons of ore. In addition five tons of concentrates were produced which assay \$105. The mine is running twenty tons of ore a day and working twenty men, says C. K. Merriam, one of the owners. A water wheel will be put in to supply power for both mine and mill. There will be a 90-foot head by putting in a 2800-foot pipe.

The government assay office returns showed one bar, \$3092.99 gold and \$16.27 silver, net; a second, \$964.09 gold and \$5.74 silver; and a third, \$3477.49 gold and \$19.20 silver.

LEMHI COUNTY.

On Indian creek near Gibbonsville, the Kittle Burton M. Co., controlled by Michigan men, has fifteen stamps dropping on ores from the Ulysses mines. After a ton days' run they cleaned up last week 149 ounces of gold valued at \$3000. H. C. Edwards, manager, says an aerial tramway between the Ulysses mines and the mill is being built. The vein is 10 feet wide, of \$25 rock.

It is reported cobalt and nickel have been discovered in the copper deposits in Whitebird district, to the extent of 5% of each of these metals. The copper deposits of this district are low grade, but the nickel and cobalt discoveries will result in their development.

OWYHEE COUNTY.

The G. W. Palmer & J. Holland group of seven claims on Florida mountain and east of the Trade Dollar mine, near Silver City, recently sold to Salt Lake parties, is to be developed under the management of A. L. Stevens, superintendent of the Addie mine.

SHOSHONE COUNTY.

R. Wilson & W. McKay of Wallace, part owners of the Mammoth mine, have bonded the Alice silver-lead mine on Ruddy gulch, between Wallace and Mulan. The ores of the Alice will be handled at the Mammoth mill. About 2000 feet of tunneling has been done in the mine, with one shaft down 65 feet.

The Wild Rose, near Pierce City, owned by R. N. J. L. and A. J. Dunn of Wallace, is reported to have produced \$30,000 with a 2 stamp mill. It was discovered eighteen months ago. Manager J. L. Dunn says it is planned to run a 300-foot crosscut near the 110-foot level, and later run a 1000-foot crosscut to reach a depth of 400 feet.

INDIANA.

The Oil Men's Association of Indiana have asked the Legislature for an appropriation of \$50,000 to be expended in deep tests in various parts of the Indiana oil fields, in order to find a new supply of oil below the Trenton limestone, which is gradually becoming exhausted. There is still a large area of untested territory.

MADISON COUNTY.

The Consumers' Gas Trust Co. of Toledo, O., have let a drilling contract to Decker Bros. of Alexandria, which calls for 600 wells. Derricks are already up for 100 of the wells between Marion and Alexandria and ten are drilling. Five more will start drilling next week.

MICHIGAN.

HOUGHTON COUNTY.

The Franklin mine, near Houghton, is producing at the rate of 400 tons of mineral per month, equivalent to 5,000,000 pounds of ingot copper yearly. The sinking of the second shaft on the conglomerate lode at the Franklin Junior mine has begun.

Work is being rushed on the new Calumet & Hecla mill at Houghton. Two heads are running and two more will drop in March. The final two will stamp by May 1. The electric power plant will be ready by the time the six heads are in operation.

It is reported some changes are to be made in equipment at the Red Jacket shaft of the Calumet and Hecla. The hoisting arrangement is not capable of

performing the service expected from it when the machinery was installed; the power is ample, as the engines are capable of hoisting a 10-ton load at the rate of 3600 feet per minute. Allowing for reduced speed at the top and bottom of the shaft, the round trip can be made in five minutes. But at present the maximum hoisting capacity of four compartments does not exceed 1200 tons daily, working twenty hours.

It is reported from Houghton that the Winona will start a new shaft, to be known as No. 3, and will be 1650 feet south of No. 2. During January the mine shipped 5000 tons of rock.

The management of the Michigan mine near Houghton has decided not to erect a steel or iron shafthouse, but use Oregon fir instead. Work on A and B shaft houses has begun.

ONTONAGON COUNTY.

St. Louis men have taken an option on the Norwich mine, near Ontonagon. The Hamilton mine, adjoining, is being explored by the Copper Crown M. Co., also of St. Louis.

MONTANA.

BEAVERHEAD COUNTY.

Petroleum is reported 12 miles south of Dillon. The surface indications are said to be favorable, but no wells have been drilled as yet.

The Tombstone M. Co., owning a group of claims in the Vipond district, near Dillon, propose to install a 10-stamp mill.

N. W. Pierson of Anaconda has taken a lease and bond on the Mayflower mine in the Big Hole district, near Wisdom, for \$20,000.

Morse & Noyes are shipping ore from their Ajax mine near Wisdom, on the upper Big Hole, to the East Helena smelter, the ore being too base to be handled at a profit in the Ajax mill.

FERGUS COUNTY.

The cleanup of the Barnes-King mill, near Kendall, during the last fifteen days of January was \$20,000. It is the intention of the owners to double the capacity of the mill within the next year.

Manager E. H. Crabtree of the Case-Wilson Cyanide D. Co., has bonded the Gilt Edge Charlie, Emma K. and Quebec claims, between Whiskey Gulch and the Gold Reef mines, near Lewiston, for \$15,000. About 200 feet of work has been done and samples assayed \$6 on ore that can be cyanided.

Manager R. K. Neill, the Kendall mine, near Lewiston, says the cost for mining the ore and extracting the bullion (by cyanide) is \$1 a ton, not including development. They are handling 7500 tons a month through a 250-ton mill. The ore shoot has been tested to a depth of 250 feet, and is 100 feet wide by 700 feet long. Neill has eighty men at work and expects the mill will be doubled in size this summer.

LEWIS AND CLARKE COUNTY.

The Gloster M. Co. mines, near Marysville, have been bought by the Longmaid Brothers of Helena. The lead has been developed to a depth of 800 feet. It is intended to operate the mill and put in cyanide tanks to extract the gold from the tailings, which formerly went down the creek. Activity in Marysville district is increasing. Development work is being pushed on Bald Butte hill under the management of C. Couch.

On the Gold Messenger, near Marysville, the tunnel is being driven to strike the lead at a depth of 300 feet. At 100 feet on the strike of the lead there are 16 feet of milling ore which carries gold values. The company will erect a 50-stamp mill to take the place of the mill destroyed last fall.

MADISON COUNTY.

Superintendent J. Smith of the Watseca M. Co. at Rochester has 100 men at work in the Watseca mine. Last week a body of \$60 gold ore was opened up on the 400-foot level. The additions to the mill and concentrator are expected to be in operation March 1, says Manager C. Hand.

PARK COUNTY.

The Bear Gulch G. M. Co. has bought a group of twenty lode claims and the Highland and David Harum placers, near Ardine.

The Bear Gulch M. Co. mines, near Irvington, are reported sold to the Kimberly-Montana G. M. Co.

NEVADA.

ELKO COUNTY.

E. O. Lee, of Salt Lake City, Utah, managing director the Dexter mine at Tuscarora, says the mine and mill are closed down indefinitely.

EUREKA COUNTY.

W. H. Tibbals has a bond and lease on

the Lincoln group of fourteen claims, near Diamond, for \$60,000. The ores carry values in gold, silver, copper and lead.

The Lincoln group of fourteen claims, near Eureka, has been bonded by W. H. Tibbals of Salt Lake City, Utah, for \$60,000. The ledges carry silver, gold, copper and lead, and development will begin this month.

HUMBOLDT COUNTY.

The dry concentrator at the Sheba mine, in Star Canyon district, is being overhauled and will hereafter employ the wet process, says President Barton of Salt Lake City, Utah. An air compressor and drills are being installed.

LINCOLN COUNTY.

The Southern Nevada mill, near Searchlight, has resumed after a shut down of seven weeks for alterations. A 28 H. P. crude oil engine was put in. The company will erect in Manvel, San Bernardino county, Cal., an 11,000-gallon storage tank for oil. The main shaft on the Blossom is down 375 feet; drifts are being run at 330 feet. An electric plant is being installed to furnish power for the pumps and for lighting.

LYON COUNTY.

Superintendent H. Smolt of Butte, Mont., has resumed work on the Blue-stone mines, near Yerington.

NYE COUNTY.

J. W. Langley and M. L. Effinger of Salt Lake City, Utah, have bought the T. J. Breen & Co. group of fifteen claims in Ray district, near Butler, for \$50,000.

Sinclair, O'Brien, Stewart and Lee, owning a group of claims 8 miles north of Pictolus, near Butler, have organized the Sierra Vista G. M. Co.

President J. W. Harris of the Rescue M. Co., at Butler, says a 25 H. P. steam hoist, with boiler, a corrugated iron shaft house and a 30-foot gallows-frame, will be put up on their group.

STOREY COUNTY.

H. Zadig says the drill is down 819 feet in the Brunswick in porphyry and quartz, and that it is certain the Chollar and Potosi never reached the east ledge in working through shaft No. 1. He considers the situation important enough to warrant resuming work through shaft No. 1 on the Brunswick.

The cost of power, as furnished by the Truckee River General Electric Co. to the mines on the Comstock Lode, is \$7 per horse power per month, based on continuous service. The saving is over 60 per cent, as steam costs \$21 per horse power per month, says the Record.

WHITE PINE COUNTY.

In the Glasgow & Western Co.'s mine at Cherry Creek last week the cable broke and the cage dropped 400 feet in the main shaft. C. Karbstein, who was on the stage, had his legs and several ribs broken.

NEW MEXICO.

COLFAX COUNTY.

A flow of gas was struck last week in the oil well being drilled at Raton at a depth of 130 feet. The volume of gas is increasing, the well now being down 600 feet, with globules of oil appearing on the surface of the water.

GRANT COUNTY.

Machinery for the Burro Mountain leaching plant in the Burros, near Silver City, has arrived on the ground, says Manager L. P. Deming, and work will begin next week.

TAOS COUNTY.

The management of the American Con. Mines Co. of Colorado Springs, Colo., operating in the Rio Hondo district, near Taos, is negotiating for another group of claims near its other property, which will give them a total of 200 acres.

OREGON.

BAKER COUNTY.

The Snow Creek group of mines in the Greenhorns, near Sumpter, has been bought by the Oregon Mines Exploration Co. F. D. Smith of Sumpter is general manager and is developing the group by a tunnel, which cut the vein at a point giving 225 feet of backs. A raise is being made from the tunnel for the shaft and drifts run under the old workings.

Eames, Simmons & Cooper, owners of the Morning mine in the Greenhorn district, near Sumpter, propose to build a mill this summer. They have been testing their ore in the Psyche mill.

Manager J. F. Meikle of the Black Eagle mine, near Sumpter, says with the 20-stamp mill running he is mining and milling the ore for 90 cents per ton, seven tons per stamp being crushed, the ore being soft.

F. O. Bucknum has bought the Copper

Butte claim, the extension of the Iron Dike, near Sumpter. Assays on the Copper Butte show \$3 gold and 6% copper, and the vein is 10 feet wide.

Superintendent T. J. Sheedy started work on the Black Jack group, near Sumpter, this week. For the present work will be principally on the Osceola, where a 150-foot tunnel has been driven.

Operations will be resumed at the Basely Elkhorn mine, near Baker City, bought recently by F. P. Hayes, president of the Beaver M. Co. A tunnel will be driven 6000 feet. All the available water rights have been secured and the whole property will be operated by electric power.

The triple-compartment shaft on the Bonanza mine at Geiser is down 1000 feet and being sunk at the rate of 2 feet 10 inches per day, says the Sumpter Miner.

Thirty stamps are dropping at the Bonanza mine, near Sumpter, on milling ore, and the other ten will be in operation by March 1st. The drift from the 800-foot level crosscut has been extended on the vein. The shaft is down 975 feet, and is expected to reach the 1000-foot point by March 1st.

The Risk tunnel, on the Sampson group, near Sumpter, is in 325 feet, says Manager F. S. Lack, and the ore shoot shows 12 inches wide, assaying \$12.

On the Porcupine group, near Sumpter, owned by the North American G. M. Co. of Seattle, Wash., a plant of development machinery will be installed, says Superintendent J. W. Doyle.

The Cougar mine in Granite district, near Sumpter, has been sold to the Hendryx-Geiser Investment Co. of Baker City for \$500,000. The property is equipped with a roller mill, roasters and cyanide plant, capacity 250 tons per day. The ore runs \$8 per ton gold.

DOUGLAS COUNTY.

Superintendent Matthews says at a meeting of the Oregon Securities Co., operating near Bohemia, it was decided to move the Helena and Musick stamp mills from their present location, to the Champion mill, making one 30-stamp mill. Twelve concentrating tables will be added to the present equipment. In the meantime the Champion mill will be run at full capacity and development carried on in the Helena, Musick and Champion mines. A dam will be built to secure water power and an electric plant installed of a minimum capacity of 1000 H. P. to operate the mill and concentrators and furnish power and light for all purposes. It is estimated that these improvements will involve an expense of \$100,000.

GRANT COUNTY.

The directors of the Dixie Meadows G. M. Co. have decided to erect a mill at their mine at the head of Ruby creek, near Prairie City, says the Miner. R. C. Reese is superintendent.

The Black Jack group of copper claims, near Susanville, have been sold to the Black Jack G. M. Co. The Prescott gold placer claims were included in the sale.

WALLOWA COUNTY.

The Electrolytic Copper M. & S. Co. has incorporated at Asotin, Wash., to operate a group of eight claims south of the mouth of the Imnaha river, near Imnaha. The company has a mill and smelter site, water power and timber reserve. R. C. Mitchell of Minneapolis, Minn., is manager. Development work will begin this spring.

PENNSYLVANIA.

Reports from Philadelphia state that the anthracite coal tonnage for January was 5,900,000 (which is the largest in the history of the business), the tolls on which to the railroads amounted to \$10,000,000. The coal companies owned by the railroads have an extra profit of 50 cents per ton.

SOUTH DAKOTA.

CUSTER COUNTY.

Tubbs & Co. report pay gravel has been opened up on their placer ground near the Old Bill mine, north of Custer. At present they are getting out dirt and preparing to sluice it in the spring when water is available.

LAWRENCE COUNTY.

E. Hanschka of Deadwood has bought the Anderson & Hogan group of claims on Bear Butte creek, southeast of Deadwood, and the initial payment made. There are 150 acres in the tract. A shaft 45 feet deep and a crosscut show the vein 12 feet wide, which assays \$8.

The cyanide mills of the Asp and Alder creek companies, on Yellow creek, a mile from Lead, are adding \$25,000 a month to the gold product of South Dakota. Their mills are working on ore bodies in the Cambrian formation.

The Oro Hondo M. Co. has bought the Keno-Fraction-Brilliant group of claims,

southwest of the Oro Hondo hoist on Whitewood creek, near Lead City, a total area of 100 acres, for \$99,000.

PENNINGTON COUNTY.

A shaft is being sunk by the McGonigal G. M. Co., on the Stella Sterling claim, southwest of Keystone. It started on a 6-inch vein of ore at the surface, which has widened to 5 feet and carries gold. Considerable water has been encountered.

An examination of the Ida Florence mine, near Keystone, is being made by T. R. Griffith of Breckenridge, Colo., for Chicago men, who contemplate buying the group. D. Sisk, superintendent, says he will sink the shaft 150 feet farther, a total depth of 350 feet.

TEXAS.

HARDIN COUNTY.

The Union Oil R. & F. Co. have their plant at Beaumont in operation.

C. E. Theile, H. E. Smith and G. A. Hill of Beaumont, propose to install a refinery at Sour Lake, the oil from several of the wells being too heavy to run through the pipe line until the sulphur and asphaltum have been extracted.

JEFFERSON COUNTY.

Drilling operations are resumed at Big Hill, near Beaumont, by the Texas Oil Fields, Limited, an English company. They are using rigs similar to those used in Baku Russia, fields, which are said to have double the force of the American standard cable rigs in drilling through rocks.

UTAH.

BEAVER COUNTY.

Manager Moore is reopening the Atlas group of mines at Shauntie under an option for \$100,000. The Atlas group of twenty claims is 9 miles southwest of Milford, near the Burning Moscow. At the bottom of the incline shaft at a vertical depth of 200 feet he has opened up a 20-foot body of ore, a concentrating proposition, and with it 2 feet of shipping ore, which assays 25% lead, 30 ounces silver and \$1.20 gold. A concentrator will be installed to handle the former.

The Reciprocity M. Co., near Frisco, reports having opened up in their tunnel a body of ore averaging \$1 in gold, 25% lead and 30 ounces silver.

The 12-ton gasoline hoists for the Harrington-Hickory and the Vicksburg, near Milford, were hauled out to the mines last week, and the 5-ton rock breaker at the Campbell mill was taken down to the smelter. Fourteen horses were used in hauling the hoists on a truck weighing three tons.

Manager G. S. Hayes the Wild Bill M. Co., operating the Burning Moscow and Wild Bill groups, near Shauntie, says they are sending to the valley smelters ores which are netting the company \$507 per carload. Of this, four cars have been shipped, with a considerable tonnage ready to ship. Three and one-half feet are showing in the breast. In the Wild Bill claim are 8 feet of ore which shows an average of 31% lead, nineteen ounces silver and 3% copper.

CARBON COUNTY.

Superintendent Lee of the Gilson Asphaltum Co., near Price, says they will ship 500 tons this month.

IRON COUNTY.

The management of the Margaret group of mines at Stateline, controlled by G. H. Smith of Salt Lake, report having uncovered a new body of ore on the 150-foot level, which averages \$13 per ton in gold and silver.

The mill and cyanide plant of the Johnny M. Co. at Stateline are in operation. The capacity is fifty tons daily. It is reported the Ophir mill will resume.

JUAB COUNTY.

At a meeting of the stockholders of the Uma Con. M. Co., of Salt Lake City, the main office of the company was removed to Robinson.

Superintendent Legg says the Uncle Sam M. Co. propose to install a concentrating plant this spring at their mines near Eureka.

It is estimated that with its own smelter the United States M. Co. is reducing Centennial-Eureka ores at one-third the cost under the contract with the American S. & R. Co. The United States property is shipping to the smelter 600 tons daily, together with 250 tons from the Centennial-Eureka.

Manager P. J. Donohue says he will reopen the Opex mine, near Robinson.

The producers of Tintic district, around Eureka, have appealed to the railways operating between the loading stations of that district and the valley smelters for such revision of the tariff as shall enable them to mine ores of a maximum value of \$20 per ton under the \$1.50 rate estab-

lished last season. With the privilege asked of the railways the producer sees how an ore which does not exceed \$10 in valuation may be to an extent mixed with that which has a valuation of \$20. This, as a rule, will conform to the requirements of the present traffic, which restricts the \$1.50 rate to a \$15 maximum, and yet, as at present, such care is required in the sorting and in averaging the contents of a lot that the production of ore under \$15 is practically heretofore of profit. It is contended that with the maximum raised to \$20 the tonnage can at least be doubled and the earnings of the railway correspondingly increased.

Superintendent B. P. Howell of the Dalton mine, near Eureka, says sinking will be resumed on the east and west vein. The shaft is down 240 feet. For some distance the shaft was sunk on the vein, but a change of dip carried the vein south while the shaft was cut under it. The direction of the shaft at bottom has been changed so that the skip can be run out and down on the vein as sinking progresses.

SALT LAKE COUNTY.

Copper production in Salt Lake valley, says the manager of one of its principal smelters, has reached approximately 3,500,000 pounds per month.

Manager G. H. Robinson, of the Tintic M. & D. Co., owning the Yampa mine at Bingham, says they have bought the Bingham Copper Belt Railway. The road will be extended from the Commercial mine down Carr fork to the Yampa.

The United States Co. will increase its bins and railroad terminal facilities at Bingham before the fifth furnace at the smelter is blown in.

Manager T. Jacobson of the Columbus Con. M. Co., near Alta, says an 8-inch shoot has been cut in the main tunnel, which assays 5% copper, 400 ounces silver, and \$6 gold. He expects to cut the main ore body in 60 feet more.

It is reported that the United States M. Co. at Bingham, with three furnaces in operation, show profits of \$100,000 a month, and with four furnaces the profits are a third greater. A fifth furnace is to be blown in. The management has decided to enter the market for siliceous ores, for treatment at its smelter.

An 8-inch ore body is reported opened up in the Columbus mine, at Alta. It was struck in the tunnel, which is in 1150 feet, and assays \$10 in gold, 402 ounces silver and 15 1/2 per cent copper. During the driving of the tunnel six fissures have been cut, and it is supposed that these will unite in one body at a point 80 feet farther in, says Manager Jacobson.

The management of the Yampa mine at Bingham will not wait the extension of the Copper Belt railway to its loading station, as originally designed, but under contract with resident ore haulers, will begin at once the delivery of its copper and gold-bearing product at the furnaces of the Bingham Con. smelters, with which it has contracted for the treatment of 30,000 tons. Superintendent W. J. Craig reports the work of opening up the ledge and blocking out the ore bodies progressing. Since the vein was cut they have driven 300 feet on its strike. The raise from the tunnel level has reached an elevation of 100 feet in ore, with the incline at 900 feet, going down in ore, the interval being 700 feet. Near the 900-foot station the incline has cut another cross-fissure, in which 4 feet of ore, carrying 20% lead, twelve ounces silver and 12% copper were shown.

WASHINGTON.

FERRY COUNTY.

C. V. Ewell, a director of the Silver Creek M. & M. Co. at Kellar, says the company will buy certain adjoining claims and equip the Gold Cord mine with machinery. A concentrating plant will be installed in the spring. Twelve men are at work in the mine, crosscutting and blocking out ore.

Superintendent Angus of the Quilp mine, near Republic, says fourteen cars of ore per week are being shipped to the smelter. A drift has been run south from the winze on No. 4 level and is in a 24-foot ore body.

The Faithful-Surprise M. Co.—the consolidation of the Faithful and Surprise groups of seven claims—at Danville made a test shipment of fifteen tons last week to the smelter at Boundary Falls, B. C., which yielded \$18 per ton net. Work will be resumed on the Faithful tunnel, in 375 feet, which will be driven to a point 200 feet below the present workings on the Surprise group.

E. W. Dickson of Seattle, special agent of the General Land Office, has seized at Republic wood and timber cut for stulls and lagging in the mines, cut on government lands in the north half of the Colville reservation. Notices are being served for payment to the government for timber cut on adjoining unoccupied

mineral claims in the district. Among mines affected by this decision is the Quilp G. M. Co., E. J. Roberts president.

The Little Chester mine at Sheridan, near Republic, has been leased to Elisman & Court for two years on 10% royalty. The Little Chester is 2 miles south of the Zila M. and has a vertical shaft down 100 feet.

The shaft at the California mine, near Republic, is being retimbered preparatory to sinking from the 500 to the 600 level. Owing to the swelling of the hanging wall country rock, the lagging has occasionally to be removed and some of the ground broken down to relieve the pressure. A larger hoist will be installed.

The Apollo M. Co., near Republic, will increase their capacity by putting in a hoisting engine of 1000 feet capacity, air compressor and machine drills. Work on the shaft will be resumed.

LEWIS COUNTY.

The Victory group of six claims, in Ibeh district, on the west fork of Silver creek, above Mineral City, has been bonded to a Minneapolis syndicate for \$30,000. There are six ledges opened up, with an average width of 5 feet, showing copper pyrites, arsenical iron and galena, carrying gold, silver and copper.

OKANOGAN COUNTY.

The Palmer Mountain Tunnel Co. has bought a site for an electric plant to be built this spring near Loomis.

The Six Eagles G. M. Co. is to build a 100-ton concentrator at the mine on the Similkameen, near Loomis.

STEVENS COUNTY.

Superintendent Manning says he has cut into a body of ore carrying tellurides in the Easter Sunday mines, near Bossburg, in the north drift from the 150-foot level. Some of the ore assays \$100 per ton.

Because of a lack of coke due to the strike in the collieries of the Crow's Nest Pass Coal Co., near Fernie, B. C., the Le Roi Co.'s smelter at Northport has closed down.

A contract has been let for 300 feet of tunnel work on the Blue Bell, on Sophia mountain, near Northport, for \$8 per foot, says D. Bennett, part owner.

A bill has been introduced in the Senate empowering J. P. Graves of Spokane to construct a dam in the Columbia river at Kettle Falls to develop electric power for mining and industrial use.

Superintendent P. W. O'Brien says he has opened up 4 inches of gold-copper ore in the tunnel of the Tenderfoot group, near Bossburg. Small lumps of tellurides are found.

WYOMING.

CARBON COUNTY.

A strike of copper ore is reported made in the Copper Blossom shaft, near Encampment, at a depth of 93 feet. The vein is 4 feet wide of quartz, 2 feet of which carries copper sulphide, making it a smelting proposition. The Copper Blossom is on the east side of Cow creek and owned by the Copper Age Co.

FOREIGN.

AUSTRALIA.

QUEENSLAND.

Payable ore was struck in the 750 level of the Mount Morgan mine in November, the assays averaging 1 oz. 4 dwts. 16 grs. The average grade of the ore treated in the second half of 1902 was 12 1/4 dwts, that of the oxidized ore being 13 3/8 dwts, and that of the muncie ore being 11 1/2 dwts. The mining of this oxidized ore was done entirely by open cutting during the last half year. Most of the ore was taken from the 196 feet and 252 feet benches. A new bench is now being made on the main tunnel level (286 feet below the original top of the mountain). This carries the open cut down to the level of the West works; and for the transport of all oxidized ore below this level an inclined drive is being put down from the main tunnel to the Grassie level, which is approximately the bottom of the oxidized ore bodies. The pay ore and overburden mined from the open cut were as follows:

	Tons.
Pay ore (oxidized).....	57,987
Overburden	53,980

Total

111,967
The half-year's supply of sulphide ore was taken from underground workings as follows: Total sulphide ore mined, 61,039 tons. In mining this 9211 tons of worthless ore were removed, of which 156 tons carrying high sulphur values were sent to the acid works for making sulphuric acid; 931 feet of driving and 743 feet of rising and sinking represent the development work for the half year. Most of this was for ore ways.

BRITISH COLUMBIA.

Manager J. B. Hobson of Cariboo stated at the mining managers' meeting held in Victoria last week that the Hydraulic G. M. Co. had in eleven years expended \$1,900,000 in equipment. It had uncovered \$1,077,000 in gold, all of which had been put back in developing the property. The Horsely Co. had expended \$350,000 in opening and equipping, and \$180,000 had been uncovered.

The Lardeau Valley Mines, Ltd., has added three more claims to its group on Tenderfoot creek, near Lardeau, making a total of ten claims, and crown grants are being issued on the entire property, says Secretary J. Mackenzie. Arrangements are being made to open the property on a large scale. The ore is concentrating and carries one ounce in gold per ton. The vein on the John L. claim is 12 feet wide, with an ore shoot of 4 feet. An aerial tramway will be constructed this summer to transport the ore from the mine to the railroad—1 mile.

Gold quartz has been found on the Coronation ground, 8 miles south of Gerard, and 1 mile from the C. P. R. R., say H. E. Rogers and H. Smidt, owners of these claims on Rapid creek. They have a tunnel in 270 feet. Assays made of samples taken across the lead in the No. 2 tunnel on the North Star claim gave \$39 in gold.

From the six leading mines of the Boundary district the tonnage for January was as follows:

	Tons.
Granby mines.....	28,824
Snowshoe.....	5,880
Mother Lode.....	10,231
Sunset.....	943
B. C. mine.....	3,240
Emma.....	3,870
Total.....	52,988

The Arlington mine, near Slokan, will erect a mill operated on the electro-magnetic separation and cyaniding processes.

Lime and brick are being hauled to Granby smelter at Grand Forks for the enlargement of the plant. Two additional furnaces making six in all, are to be installed this spring, giving a capacity of 2200 tons. To the electrical plant a transformer capacity equivalent to 1200 H. P. will be added, making a total of 1700 H. P. supplied by the Cascade Power Co. The Granby Co. has 1100 H. P. developed at its own power house on the north fork of Kettle river. The output of blister copper now amounts to 1000 tons monthly.

The Rock Creek coal lands west of Midway have been sold to the Ashnola Smelter, Ltd. A 4-foot seam of coking coal has been exposed and development work will begin by March 1st. A battery of coke ovens will be built. A 12-mile section of the Midway & Vernon Railroad will be built to connect the coal fields with the C. P. R. and Great Northern at Midway.

Manager C. H. Mackintosh, of the Giant M. Co., near Rossland, says the samples of ore sent for analysis to metallurgists in Swansea, Wales, returned: Molybdenum, 24.2%; nickel, trace; cobalt, 1%; bismuth, 0.19%; arsenic, 1.8%; sulphur, 23%; copper, trace; lead, trace; gold, 4.14 ounces per ton; silver, 1.02 ounces per ton; silica, 35%; iron, 12.5%; oxygen, lime, magnesia, 2.3%. There being no plant in the Kootenays which will recover the molybdenum, the ore will be shipped to Swansea, Wales.

A second gold bar, weighing 150 ounces, has been shipped by the Broken Hill M. & D. Co. and represents the balance obtained from the first cleanup at the Wilcox mill, near Ymir. The run was five weeks and the product \$1000 in bars and concentrates, running \$40 per ton. One carload of concentrates has been shipped. The ore averaged \$12 per ton.

Miners of Nanaimo have gone on strike, 800 men going out against the Western Fuel Co. of San Francisco, which recently acquired the mines. The miners are asking for an advance from March 1 to 80 cents a ton, 25 cents a day for using safety lamps, claiming that coal cannot be got under as quickly with the safety lamps, and they ask for \$1 a ton more for mining in the lower level, which runs under the sea.

The output of coal from the Crow's Nest Pass coal mines for January was the largest in the history of the company, being 55,000 tons.

The miners at Michel, Fernie and Morrissey, in the mines of the Crow's Nest Pass Coal Co., are out on strike. The main reason seems to be the rate of 40 cents a ton at Morrissey, which the miners claim is insufficient. Manager Tonkin says the company is prepared to resist the demands of the men, if need be for eight months. The War Eagle and Centre Star mines at Rossland are arranging to get coal from Galt, Alberta; and Le Roi mine will get coal from Washington. The strike has caused the closing of Le

Roi Co.'s smelter at Northport, Wash. Both the Trail and the Granby smelters are said to have but a short supply of coke and coal on hand. The British Columbia C. Co., at Greenwood, have a month's supply of coke in their bins.

The Boundary Coal Mines, Ltd., has been organized at Spokane, Wash.; C. E. Mitchell, E. T. Bartlett, W. H. Myers, P. F. Godenrath, W. S. Fairfield, G. A. Macleod. The company has obtained licenses covering 2580 acres. In the coal basin 60 miles north of Grand Forks, toward the head of the North Fork of the Kettle river, the coal is bituminous. It is intended to use a portable horse-power diamond drill to prospect.

CANADA.

The gold production of Canada for 1902 was 943,391 ounces, valued at \$19,500,000.

MEXICO.

CHIHUAHUA.

The Montezuma group of gold mines in the Topago district have been sold to the United M. & E. Co. of Los Angeles Cal., for \$5,000,000. It is stated that \$500,000 will be expended on development and equipment of the property.

The semi-annual report of the Palmarejo & Mexican Gold Fields, Ltd., for the six months ending Dec. 31, 1902, has been issued and shows that 16,470 tons of ore were crushed and 14,062 tons treated, showing a gross product of \$259,400, of which \$72,550 was gold and \$186,850 silver. The profit was \$78,625. This period covers October, when by reason of an accident to the conduit, the profit was only \$1825. The quantity of ore crushed is, approximately, 10,815 tons dump ore, 5165 tons Palmarejo mine ore and 490 tons La Patria ore. The results have not reached the estimate, the principal causes being insufficiency of miners, deficiency in cyanide tank capacity and loss through slimes. Four additional tanks of large capacity are being erected. Two will be completed by the middle of February. A large pit has been built to save slimes for future treatment. Manager A. P. Griffiths recommends a slimes plant.

The Montezuma group of gold mines, in the Topago district, have been sold to the United M. & E. Co. of Los Angeles, Cal., and \$500,000 is to be used on development and equipment this year.

F. Kahn shipped fifty-nine sacks of ore last week, assaying \$800 gold per ton, from La Gloria, Santa Elena y Anexas, near El Oro.

Arrillano, Urias & Co., having concessions for two smelting works with a minimum capacity of 200 tons daily, one to be erected at Parral and the other at Jimenez, will begin operations this month.

The Dolores mine is locally reported sold to the Venture Corporation of London, England, for \$1,250,000.

HIDALGO.

The mines at Pachuca are producing 7,000,000 ounces of silver annually.

SAN LUIS POTOSI.

The silver mine of La Paz in Matehuala has struck a new ore body. The production is 4000 tons monthly of 50-ounce ore, which is being taken out by leasers.

SONORA.

Secretary R. V. Daniels of the Gold Treasure M. Co., 8 miles from Naco, on the southwest slope of San Jose mountains, says a road will be built up the canyon to within 1000 feet of the mine, which will be connected with the property by a gravity tramway. The present plan is to ship, but a reduction plant will go in later. Their group consists of 724 pertenencias.

The Yaqui S. & E. Co. has been incorporated by Toledo, Ohio, men, with headquarters at Hermosillo, and will build a 100-ton smelter at San Antonio de la Huerta, 100 miles east of Hermosillo.

The Sonora E. & M. Co. has incorporated at Douglas, Ariz.; R. N. and J. M. French, L. F. Martinez, F. Castro, A. C. Lubbert and G. H. French, to operate a silver mine in the La Purica mountains, a copper group of 100 pertenencias in the Sierra de la Ceniza, and a silver-lead mine on the opposite side of the mountain from the Pavo Rico; also, a group of copper prospects 25 miles southeast of Douglas.

The Bisbee Review says the smelters at Cananea are closed down for an indefinite period on account of the strike on their narrow-gauge railroad.

The Cananea Herald says the interests of the Creston-Colorado M. Co. at Minas Prietas have been sold to a syndicate of Chicago and New York men, headed by J. W. Gates, for \$6,000,000.

Twelve miles south of Atlix, in Altar district, N. H. Brown & Co. of San Bernardino, Cal., are developing the San Augustine mine. They have a ledge 60 feet wide which runs 6% copper, 33 ounces silver, and some gold. A reduction plant is proposed.

W. Lahbert & Co., of Minas Prietas, are developing a copper group near San

Javier, in Hermosillo district. They will erect a smelter.

T. P. Lloyd & Co. have bonded the Beaverich mine, 20 miles north of Sahuaripa, and near the Yaqui river. The Bufo M. & M. Co. are shipping ore and concentrates from their mines near Sahuaripa.

W. E. Defty has bought a one-fourth interest in the Yaqui mine, adjoining the Martha, owned by Talbot & Co., near Altar.

MONGOLIA.

The Franco-Russian Co. des Aimaqs, V. Von Grot manager, are developing quartz and hydraulic properties in Touchetoukon and Tsentsenkan districts. Assistant Manager G. A. Blegow says he will this spring open up additional hydraulic ground in the eastern part of their holdings.

SOUTH AFRICA.

From the new alluvial deposits worked by the Pretoria District Diamond Co., the yield is reported to have improved from 30 carats per 100 loads to 50 carats per 100 loads in recent washings.

At the Wolhuter mine, near Johannesburg, burg, milling operations have not been started since the war, owing to scarcity of native labor. Work has been concentrated on opening up the deeper levels of the mine. The manager estimated the total cost of this sinking by white labor at little over £20 per foot, being 20% higher than the cost by Kaffir labor, if employed in the usual manner on this class of work, and says he has concluded that white labor can never successfully compete on economical grounds with native labor on the mines.

The report of the Chamber of Mines of the Transvaal shows that the production in December was 196,023 ounces of fine gold. This makes the production for the year 1902 a total of 1,704,410 ounces (\$35,230,155), or nearly one-half of that reported for 1898, the year before the outbreak of the war.

SOUTH AMERICA.

ECUADOR.

The Zaruma is being worked. The South American Development Co. are the owners, in the district of Zaruma, Province of El Oro. All the work is through tunnels, the lowest and principal tunnel being 2300 feet in length, reaching a depth of 650 feet. The rock is blue and white quartz, carrying 10% sulphides of lead, zinc, iron and copper. Some free gold is found. The formation is andesite. There are placer mines in the Province of Esmeraldas, owned by the Playa de Oro M. Co. of New York City.

GUIANA.

No lode mining is carried on in the district. The only mineral produced is gold, which is obtained in the placers. Occasionally specimens of ore are found, but no considerable paying deposit has ever been discovered. The country rock is similar in all the mining districts of the Guianas, and is diabase and quartz porphyry schists. The payable quartz is found in masses of decomposed diabase. The placer claims are numbered, but no record of production is kept. The annual production is reported at about 200,000 ounces.

PERSONAL.

F. JAGER has returned to Chicago from Prescott, Ariz.

P. L. KIMBERLY has returned to Salt Lake City, Utah, from the East.

W. A. ALDRIDGE of the Trail smelter, Trail, B. C., is in Spokane, Wash.

J. H. GRAHAM has returned to Baker City, Or., from a trip to Pittsburg, Pa.

J. R. BOND is superintendent of the Green Canon mine, near Aguilar, Colo.

B. F. GRAHAM of B. F. Graham & Co., Bisbee, Ariz., has gone East on business.

J. BEDIER is superintendent of the North San Poil mine, near Republic, Wash.

F. H. BULL of the Bull-Kimberly mines, Utah, is in Salt Lake City from the East.

R. S. BAVERSTOCK of Los Angeles, Cal., is examining mining properties at Nacozari, Mexico.

D. F. MEIKLEJOHN, E. M., is at Sierra City, Cal., where he is working chlorination tailings.

L. W. FELT, manager of the McCabe mine, McCabe, Ariz., has returned from Denver, Colo.

P. M. MCCREE is manager of the Blackbird M. Co. mines in Copper gulch, near Milford, Utah.

J. W. FINCH of Victor, Colo., has been

reappointed state geologist of Colorado by Governor Peabody.

H. N. GAILER, assistant manager of the Granby smelter at Grand Forks, B. C., is in Spokane, Wash.

MANAGER P. W. MADSEN of the Century mine of Park Valley, Utah, is in Chicago on business.

F. N. BURK has resigned as secretary and manager of the Bertha mine, near Idaho Springs, Colo.

H. F. POLAND, manager of the Indian Co.'s mines and mill at Pony, Mont., is traveling in California.

GEO. E. NOLAN, manager Nevada Engineering Works, has returned from San Francisco to Reno, Nev.

W. B. DOUGALL JR., treasurer of the Bingham-Centennial Co. of Bingham, Utah, is in Denver, Colo.

R. D. LEONARD, superintendent of the Pacific Development Co., near Elk City, Idaho, is in Butte, Mont.

G. WEHE has resigned as manager of the Night Hawk M. Co. on the Similkameen river, near Loomis, Wash.

E. E. ANFORD has succeeded G. Bertsey, Jr., as superintendent of the Tykoon M. Co., near Keystone, S. D.

W. A. STEVENS of the Buffalo Hump mines, Buffalo, Idaho, is in San Francisco, Cal., on his way to Inyo county, Cal.

TREASURER MUCKLOW of the Majestic M. Co. has returned to Hartford, Conn., from their mines near Milford, Utah.

A. LAWRENCE has resigned as assayer at the Cave mine, near Milford, Utah, and has gone to Salt Lake City, Utah.

BENJ. BLANCHARD is now general manager Iron King mine, near Prescott, Ariz., operated by the American Copper Co.

G. D. B. TURNER, manager of the J. I. C. mine, has returned to Park City, Utah, from an extended trip to Europe.

E. W. GRIFFITH of Salt Lake City, Utah, has been inspecting the Martha Washington mine in Tintic district, Utah.

W. A. ENGLE of Attleboro, Mass., is at Boulder, Colo., inspecting the Wall Street property, in which he is interested.

A. J. FROELICH, superintendent of the Hull mine, near Groveland, Cal., has returned from a business trip to San Francisco, Cal.

JAS. A. MCILWEE is superintendent of the Practical G. M. & L. Co. at Cripple Creek, Colo., and John McIlwee is assistant superintendent.

PRESIDENT J. W. RUSSELL of the Blackbird M. Co., near Frisco, Utah, has gone East, accompanied by Directors Van Tassel and Kimball.

L. B. SKINNER, formerly with the Standard mill at Colorado City, Colo., is superintendent of the Portland mill at Cripple Creek, Colo.

T. H. ELLIS, president and manager of the Yellow Jacket M. Co., at Wyndham Bay, near Juneau, Alaska, is in the East on company business.

H. C. TAYLOR, a manufacturer of Worcester, Mass., is in Salt Lake City, Utah, visiting mining properties in that section in which he is interested.

S. LEVY, assistant manager of the Western M. & E. Co., has returned to Salt Lake, Utah, after a visit to the New Pass mines, near Austin, Nev.

F. CAMERON, general superintendent of the Utah Coal Co., at Castle Gate, Carbon county, Utah, has changed his headquarters to Salt Lake City, Utah.

H. P. GORDON has been appointed superintendent of the New Montezuma mine at Nashville, El Dorado county, Cal., vice T. B. Dillon, resigned.

O. TOWNSEND has resigned as manager of the Baby McKee & Last Chance Con. Co., near Sumpter, Or., and will be succeeded by Superintendent Hennessy.

G. WYMAN, who has been superintending development of the Animas mine, of which he is part owner, at San Javier, Sonora, Mexico, has returned to Cleveland, Ohio.

SUPERINTENDENT J. A. KIRBY of the Daly West mine at Park City, Utah, has returned from Nevada City, Cal., where he has been starting development on the Polar Star mine.

H. E. FORSTER, operating the Trade Dollar mine at Republic, Wash., president of the Curlew M. Co., accompanied by T. O'Brien, the vice-president, is in Spokane, Wash. They will return this week via Vancouver and Golden, B. C.

JAS. CONSTABLE, formerly manager Phoebe Exploring Association, Ltd.,

London, England, is now superintendent Virginia mine, Greenhorn, Or., operated by the N. P. M. Co. of Seattle, Wash.

R. B. HARPER of San Jose, Cal., is general manager and consulting engineer of the Santa Teresa Quicksilver M. Co. of Boston, Mass., operating the Santa Teresa mine, near San Jose, Cal., and mines in Mexico.

ASSISTANT MANAGER G. A. BIGELOW of the Franco-Russian Co. des Almaks in Touchetoukon and Tsetsenkan, Mongolia, is in San Francisco, Cal., and leaves this week for the properties in northern Mongolia.

FRANZ MEYER, Ph. D., metallurgical and chemical engineer, formerly manager of the Grillo Works at Oberhausen, Germany, has been appointed general manager of the Wetherill Separating Co. The office of this company will hereafter be at 68 Broad street, New York.

Commercial Paragraphs.

D. B. BISBEE has bought the laboratory of G. H. Ellis, Chicago, for assaying and mine examination.

J. H. KINKHEAD has shipped one of his ore crushing mills to Tonopah, Nev., to the pioneer mill of that camp.

O. R. MORRIS is finishing the quartz mill and cyanide plant construction by Joshua Hendy Machine Works at the Iron King mine, 16 miles from Prescott, Ariz.

THE Union Iron Works, San Francisco, Cal., report having received the past week a contract for a 40-stamp mill for the Fremont Con. M. Co. in Amador county, Cal.

THE C. O. Bartlett & Snow Co. of Cleveland, O., write that they have lately received orders for their special Common Sense conveyor for conveying clinker, capacity 1750 barrels per day, from the Bronson Portland Cement Co., Bronson, Mich., also from the Omega Portland Cement Co., Jonesville, Mich.; also have an order for one of 1000 barrel capacity from the Egyptian Portland Cement Co., Detroit, Mich.

THE Wm. Powell Co., Cincinnati, O., state that they are now making an improved valve which they designate as their White Star, and "the peculiar feature about it is that it is not only re-grinding but the disc is reversible, that is, being double faced, after one side is worn out the disc can be turned over and a new face brought into use. In addition to this, when the disc is entirely worn out, it can be replaced with a new one, so it combines the two essential features of all high-grade valves in the market."

Catalogues Received.

"Cement Machinery" is the subject of Catalogue No. 15 of the Allis-Chalmers Co., Chicago, the sixth edition of which is issued in sumptuous style. There are seventy-two pages of finely illustrated description of machinery designed for the economical manufacture of Portland cement.

The 1903 catalogue and price list of Keuffel & Esser Co., 127 Fulton street, New York, is a 500-page octavo with all the solidity of a bound book and all the flexibility of a pamphlet. It is a complete exposition in black and carmine of this firm's makes of drawing materials, surveying instruments, and general supplies used by engineers in office or field work. About 400 of the illustrations are copyrighted. The present is the thirty-first edition of this work and excels even its predecessors. Its price is 50 cents. The company's branch offices are at 111 Madison street, Chicago; 708 Locust street, St. Louis, Mo., and 303 Montgomery street, San Francisco, Cal.

Books Received.

"Engineering for Land Drainage." This is a manual for the laying out and constructing drains for the improvement of agricultural lands by Charles G. Elliott, C. E., 232+VII pages, 41 figures; cloth, \$1.50. It gives much information on the subject indicated in the title, and will prove of great value to those who have low, marshy tracts of land which they wish to till or otherwise improve. John Wiley & Sons, New York and London.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR WEEK ENDING FEB. 10, 1903.

- 719,987—SPEECH RECEIVER—S. J. Ballard, Los Angeles, Cal.
720,115—HORSESHOE CALK—A. Corcoran, Seattle, Wash.
720,128—SALTING MACHINE—J. W. Gheen, Astoria, Or.
720,345—DISPLAY PACKAGE—P. R. Hazeltine, Los Angeles, Cal.
720,353—VEHICLE WHEEL—R. E. J. Hery, Grass Valley, Cal.
720,443—CABLEWAY—W. King, Blue Lake, Cal.
720,158—TWIN CUTTER—Knowles & Dickson, Santa Ana, Cal.
720,260—ROLL LAP ROBE—Kutscher & Auradon, S. F.
720,279—RURAL MAIL BOX—M. S. Norton, S. F.
720,471—PRESERVING JAR—Mary E. Perley, Peris, Cal.
720,176—SOIL SCRAPERS—G. N. Perry, San Diego, Cal.
720,476—BOTTLE—Plummer & D. vis, Salem, Or.
720,283—REMOVING SURPLUS METAL—Geo. Porter, S. F.
720,480—CRUSHING MILL—H. U. Prindle, Sacramento, Cal.
720,481—PRINTING PAPER BAGS—Purdin & Haskins, Medford, Or.
720,071—SYRINGE—J. I. Richards, S. F.
720,288—FRUIT PITTER—O. L. Scott, S. F.
720,495—OIL BURNER—C. W. Selvert, Los Angeles, Cal.
720,291—RAILWAY CAR—G. E. Smith, Pasadena, Cal.
720,080—FLY ESCAPE—W. H. Spate, Anaheim, Cal.
720,298—DOFFER—D. M. Sullivan, Rio Vista, Cal.
720,537—UMBRELLA—A. S. Venen, Forestgrove, Or.
720,548—PAPER HOLDER—R. G. Whitlock, Los Angeles, Cal.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

DOFFERS FOR FIBER MACHINES.—No. 720,298. Feb. 10, 1903. D. M. Sullivan, Rio Vista, Cal., assigned to Thomas & Ettinger, a firm of Rio Vista, Cal. This invention relates to improvements in machines for working hemp, flax ramie, or other similar fiber by which the stalks are crushed and broken so as to separate the fiber from the woody portion, and relates particularly to what is known as the "doffer," by which the fiber is carried successively from one portion of the machine to the other. It consists in the combination with a cylinder and carrier of a drum located between these two, and a cover having a series of transverse lines of holes made at intervals. A series of hollow guides are carried by the drum and springs within the guides. A series of transverse bars are arranged around the drum and have fixed points or spurs extending in line with the holes in the drum cover, said bars having their ends extended beyond the ends of the drum, and provided with rollers; said bars also have inwardly extending end portions disposed outside of the vertical plane of the sides of the cylinder, which fit the said guides and seat upon the springs therein. Cam tracks arranged outside the ends of the drum engage the rollers and retract the bars.

RURAL DELIVERY MAIL BOX.—No. 720,279. Feb. 10, 1903. M. S. Norton, San Francisco, Cal. This invention is especially designed for the delivery and collection of mail matter in rural districts and provides a box of such contour as to give the greatest capacity and resistance to injuries with the most economical construction and means by which it is readily opened to its fullest extent or locked and hermetically sealed against the elements when closed. It consists of various mechanism, including an indicator, interlocking disks, a lock, a means for the raising and lowering of the door is opened and a lever arm whereby the disks and indicator are turnable when released.

APPARATUS FOR REMOVING SURPLUS METAL FROM COATED ARTICLES.—No. 720,283. Feb. 10, 1903. George Porter, San Francisco, Cal. This invention relates to an apparatus designed for the cleansing and preparation of nails which have been previously coated with molten zinc or equivalent protecting metal and which process is technically called "galvanizing." It is difficult to clean nails of surplus adherent metal and put them in condition for use, also many times the nails become stuck together in masses when they cool by reason of this surplus metal. By means of this apparatus the surplus fused metal adhering to the nails, etc., can be cleaned off and the nails left in a smooth, merchantable condition.

FRUIT PITTER.—No. 720,288. Feb. 10, 1903. O. L. Scott, San Francisco, Cal. This invention consists of a circular revoluble disk, having an eccentrically formed opening made through it adapted to receive the fruit, and elastic cutting blades are fixed in one side of the opening, so that when the fruit is placed within the opening these blades are inserted upon each side of the pit, the outline of which they follow. The edge of the opening forms a blade, which splits the fruit, and means are provided for revolving the disk upon its supporting guide, so that the fruit being held while the disk is revolved, the inner edge of the opening will cut the fruit around the pit, while the blades follow the outline of the pit and sever the meat therefrom. The object of the device is to provide a means for rapidly splitting fruit having pits, such as peaches and the like, and at the same time separating the meat from the pit.

ROLL LAP ROBE OR STORM APRON.—No. 720,260. Feb. 10, 1903. A. G. Kutscher and J. G. Auradon, San Francisco, Cal. This invention relates to improvements in attachments for bugles and other vehicles by which a lap robe may be rolled up or unrolled, much after the manner of a window shade. Its object is to provide a means by which a robe or apron may be quickly removed out of the way of the occupant of a vehicle, as when it is desired to alight, and which will always be in position across the vehicle in readiness to be

drawn up when required. It consists of a spring-actuated roll carrier, means for pivotally supporting its ends, a lap robe secured thereto, said robe having extended lateral portions, and means for folding the robe so it may be wound upon the rollers.

VEHICLE WHEEL.—No. 720,253. Feb. 10, 1903. R. E. Jeffrey, Grass Valley, Cal. This invention relates to improvements in wheels for automobiles and other vehicles, and particularly in that type of wheels having separable hub sections. Its object is to simplify the construction, improve the means for adjusting the spokes and adapt the use of wooden spokes to a metal rim. Hitherto it has been customary to confine the use of wooden spokes to rims of like material, and converse to use only metal spokes with metal rims. The advantages of a combination of metal rim and wooden spokes are recognized, and it has been one aim of the present invention to afford a practicable means of effecting such combination.

Latest Market Reports.

SAN FRANCISCO, Feb. 20, 1903.

METALS.

SILVER.—Per oz., Troy: London, 22s 3d (standard ounce, 925 fine); New York, bar silver, 47½c, refined (1000 fine); San Francisco, 47½c; Mexican dollars, 38 @39c San Francisco, 37½c New York.

COPPER.—New York: Standard, \$12.35; Lake, 1 to 3 casks, \$12.90; carload lots, \$12.00; Electrolytic, 1 to 3 casks, \$12.85; carload lots, \$12.50; Casting, 1 to 3 casks, \$12.75; carload lots, \$12.50. San Francisco: \$14.00. Mill copper plates, \$17.00; bars, 18@24c. London: £57 17s 6d spot per ton.

No material change in the copper market has developed the past week. A small quantity of the metal has been sold in New York at 13 cents, but it cannot be said that it is quoted at that price, though closely approximating it. Those in a position to forecast the market say it will be a matter of short time when 13-cent copper will be an accomplished fact.

LEAD.—New York, \$4.12½; Salt Lake City, \$3.50; St. Louis, \$4.00; San Francisco \$4.50, carload lots, 4½c 1000 to 4000 lbs.; pipe 5½, sheet 6, bar 5½c; pig, \$4.75. London: £11 15s per long, ton = 2.55c per lb.

SPELTER.—New York, \$5.05; St. Louis, \$4.60; London, £20 17s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9½c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 10c; 300 to 500 lbs., 11c; 100-lb. lots, 13@15c.

TIN.—New York, pig, \$29.30@29.35; San Francisco, ton lots, 31c; 500 lbs., 31c; 200 lbs., 31½c; less, 32c; bar tin, 31½c @37½c. London, £133 12s 6d spot.

PLATINUM.—San Francisco, crude, \$18.00 @ oz.; New York, ingot, \$19.00 per Troy oz. Platinum ware, 75@80c per gram.

QUICKSILVER.—New York, \$45.50@46.00; large lots; London, £8 15s; San Francisco, local, \$45.00 @ flask of 7½ lbs.; Denver, \$49.50. Export, \$43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 35c; Eclipse, 37½c.

ALUMINUM.—New York, No. 1, 99½c pure ingots, 35c; No. 2, 90½c, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 20c; San Francisco, Plumbers', 100-lb. lots, 16.5c.

NICKEL.—New York, 50@60c @ lb.; ton lots, 45@48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$23.10; gray bar, \$20.50; San Francisco, bar, 3c @ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$30.00; open hearth billets, \$31.50; San Francisco, bar, 7c to 12c per lb.

Special rates for carload lots.

GENERAL SUPPLIES.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1** 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2* 35%, carload lots, 9½c; less than one ton, 11½c. No. 2** 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2 per keg.

CAPS.—3x, \$5.50 per 1000; 4x, \$5.50; 5x, \$8; Lion, \$9, in lots not less than 1000.

FUSE.—Triple tape, \$3.50 per 1000 feet; double tape, \$3.00; single tape, \$2.50; Hemp, \$2.10; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10½c @ set; 14 oz., 40s., 9½c.

CEMENT.—Germania, \$2.50 @ 2.75; Hewmoor, \$2.90; Trowell, \$2.90; Portland, \$2.50@2.75 per bbl.

LIME.—Santa Cruz, \$2.25; Roche Harbor, \$2.25 per bbl.

OILS.—Lined, boiled, bbl., 56c; cs., 61c; raw, bbl., 54c; cs., 59c; Lucol oil, boiled, bbl., 50c; cs., 55c; raw, bbl., 48c; cs., 53c. Kerosene—Pearl, per gal., 22½c; Astral, 22½c; Star, 22½c; Extra Star, 25½c; Eocene, 24c; Elaine, 27½c; Water White, in bulk, 16c; Mineral Seal, iron bbls., 18½c; wooden bbls., 21c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½c; 86° Gasoline, bulk, 21c; do., cs., 27½c; 63° Naphtha or Benzine, deodorized, in bulk, per gal., 16c; do., in cs., 22½c; Lard Oil, E. W. S., bbl., \$1.00; cs., \$1.05; Neats-foot Oil, pure, bbl., 75c; cs., 80c; cs., No. 1 bbl., 57½@60c; Sperm, crude, 50@60c; Natural White, 65c; Bleached do, 70c; Whale Oil, cs, 50@55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., per lb., 6½c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead—In bbls., 1 ton and over, 6c; do. in kegs, 6½c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., 6½c.

LITHARGE.—Pure, in 25-lb. bags, 8 @9c per lb.

BONE ASH.—Extra No. 1, 5@6c per lb. No. 1, 4@5c.

BORAX.—Concentrated, 7@9c per lb.; powdered, 9@12c; fused, 25@30c.

BISMUTH.—Subnitrate, per lb., \$1.60.

BONE ASH.—4c @ lb.

BORAX.—Crystal, 7c; calcined, 25c.

COPPER.—Sulphate, 5@7c.

MANGANESE.—(90% and over) @ lb., \$1.25.

MOLYBDENUM.—25c. @ gramme; 1000 grammes=2½ lbs.

CHROMIUM.—(90% and over) per lb., \$1.25.

SODIUM.—Metal, @ lb., \$1.25.

MERCURY.—Bichloride, @ lb., 90c.

PHOSPHORUS.—(American) @ lb., \$1.00.

SILVER.—Chloride, @ oz., 90c@ \$1.00; nitrate, 55c.

URANIUM.—Oxide, @ lb., \$3.50.

ZINC.—Metallic, chemically pure, @ lb., 50c; dust, @ lb., 10c; sulphate, @ lb., .04c.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

Whole No. 2223.—VOLUME LXXXVI.
Number 9.

SAN FRANCISCO, CAL., SATURDAY, FEBRUARY 28, 1903.

THREE DOLLARS PER ANNUM.
Single Copies, Ten Cents.

AN interesting phase of the history of Cripple Creek district, Colo., is found in the numerous strikes of rich ore made in shallow workings, after the district had come to be looked upon as a deep mine camp. It would indicate that in the haste to gain great depth much that was valuable, and would yield a profit at comparatively nominal expense of time and money, had been overlooked. The more thorough development of the numerous mines has resulted in a better understanding of the fissure system, and this in some degree is responsible for these numerous superficial discoveries. Some companies in exploration are extending their upper levels in the light of this broader knowledge pending the completion of the first drainage tunnel. This finished, the era of deep mining will receive a

Fig. 1—General View Interior Ophir Mill, San Miguel County, Colo. (See page 135.)

Fig. 2—The Batteries Ophir Mill, San Miguel County, Colo. (See page 135.)

new impetus, but it is unlikely that the leasers will lose sight of the highly profitable, more superficial deposits.

IN Idaho there has recently been much discussion over the various forms of mine taxation proposed. In Shoshone county the authorities assessed the mines at what they considered a proper valuation, upon which the tax levy was made. The mine owners and managers positively refused to pay this tax, though asserting their willingness to pay taxes on the improvements made on the mines as they had done for years. This course led to much discussion and the State Legislature has recently passed a law taxing the net output of mines of the State and the bill has been signed by the Governor. Up to the present no adverse comment or opposition to the law has been reported.

Fraudulent Mine Promotion.

In these days when so many mining stocks are being offered to investors it would be both unwise and untrue to say that most of them are frauds, and should be let alone. There are many ways in which those contemplating investment in mines, but who are unfamiliar with mines and mining methods, may get reliable information concerning the particular stock offered them. The statements made by some promoters, in some of the numerous prospectuses, are so palpably false as to require no comment, as the attempted deceit is readily recognized by mining men, but the inexperienced are the easy victims of these unprincipled men with their fake schemes. The language employed by some promoters in their prospectuses bears the stamp of honesty, and even cautions investors against being duped by false representations. Certain paragraphs give ostensibly scientific descriptions of the rocks and geological formations. These sound well to the uninitiated, but the blunders in phraseology and orthography at once pronounce the writer of them as a pretender, for there are few qualified mining engineers who will lend themselves to swindling schemes of the description noted. The "words of caution" found in these fake prospectuses would be amusing if it were not for the mischief they are calculated to work.

A great many newly organized companies place the capital stock in the millions when the property is in its early stage of development, worth only a few thousand at most. The capitalization is not based upon values, but is fanciful, and dividing the stock into a large number of shares makes it seem cheap to the would-be investor. If the property has the elements of profit in it when equipped and managed it will pay; and if it pays a net profit at all it will pay it on a capitalization of several million dollars as well as on one of a few thousand.

Placing the par value of the stock at a high figure does not make the stock worth more, nor less. That there is, or can be, any real connection between the actual value of a mine and its capitalization is a delusion, and where the promoter undertakes to demonstrate that there is such connection, particularly in a partially developed mine, the connection is merely fanciful. "Overcapitalization is dangerous." This is true of industrial enterprises more than of mining concerns, but is not nearly so dangerous as exaggerated statements of value of ore in sight.

The Sampling of a Mine.

"Mine Sampling," "Ore in Sight," "Valuation of Mines," and "Mining Reports," are the titles of editorial and communicated articles recently appearing in mining journals in various parts of the country. The frequency with which articles of this character appear is an index of the great interest being taken at this time in the subjects indicated.

Any person contemplating mine investment, either as the purchaser of all or a portion of a mine, or simply as an investor in stock of an organization owning the mine, must have an unusual interest in the value, real and prospective, of the property. The examination of a mine is the first step in determining its value, and deductions made from observed facts should constitute the report.

The former comprises a careful, systematic inquiry into the extent and value of all ores exposed in the mine workings, and this includes the responsible and sometimes difficult task of "mine sampling." In making deductions the engineer is called upon to calculate the no less responsible problem of "ore in sight." The wide difference sometimes noticed in the estimates of "ore in sight" between the calculations of the engineer making an investigation for the seller, and those of the engineer who examines and reports for the buyer, probably represents the influence of the opposite interests. There is, or should be, little difference in the results obtained in careful, systematic sampling of the ore that can actually be seen and sampled, but there is often a startling discrepancy in the reports of "ore in sight" as calculated by different engineers.

To arrive at a basis for establishing the value of a mine, the engineer should be provided with accurate maps of the mine workings, showing them in plan, and in both transverse and longitudinal section. If none are available, they should be made. The workings should be divided into sections or blocks of approximately uniform size extending along the surface of the exposed ore. In drifts, for instance, the back, if not timbered, lagged, and consequently inaccessible, should be divided into blocks 25 to 50 feet in length, and within this length a stated number of samples should be taken, say every 5 feet, or every 10 feet. In high-grade ore the lesser distance is productive of more accurate results.

The method of sampling must be determined by the experience of the engineer. Manifestly a vein consisting of soft, easily cut material in which the mineralization appears to occur with uniformity, should not be sampled in the same manner as a vein of hard, flinty quartz in which the values are known, or believed to be "spotted." In the former instance a representative sample—one which may be depended upon—can be obtained by "channelling" to a depth of 1 or 2 inches and like width across the vein, at the intervals stated, care being taken that the quantity of material removed from each portion of the cross section be of equal amount. Where hard and soft streaks occur alternately the difficulties are greatly multiplied, and larger samples must be cut. In the case of the hard vein with spotted values, or, as is sometimes the case, where the rock is hard, and the values, though not disseminated with marked unevenness, are in fine, easily disturbed material, falling out of the vein upon being struck with a pick or hammer, samples taken by hand cannot safely be depended upon to give reliable results. In these and similar cases, and in large masses of low-grade ores, mill runs are the only reliable means of arriving at the desired information. What applies to drifts is also applicable to shafts, raises, winzes and stopes. The assays should be given a running number which should be carried throughout the entire mine. By this means there is less likelihood of confusion. On

the map should be entered the width of vein, and result of assay of each sample taken, together with its number.

The several blocks may be designated either by number or letter. As a check, from each rejected portion of the samples obtained in any block should be taken an amount representing relatively the width of the vein at the place sampled, and this worked down to form an extra check sample for the block from which it came. No sample should be rejected which has been properly taken, whether rich or poor in values. If rich simply as a check, two additional samples may be taken, one on either side of the suspicious sample, within 1 foot or 18 inches of the original. If high results are again obtained, the original sample should be allowed to stand as representative, but the two check samples are entered separately and marked "check."

Proceeding in this thorough and systematic manner, the engineer may ascertain almost exactly the value of the ore along the actually exposed portions of the mine workings.

It is when he attempts to generalize these carefully obtained results in estimating "ore in sight" that the greatest care and judgment must be exercised. The actual operation of veins for years in many regions has abundantly proven their vagaries, and indeed "things are not what they seem" in mines. When estimating ore beyond the range of actual vision—the ore that is still in the vein encased in its rock walls—the engineer can only be guided by two considerations—his experience elsewhere in veins of similar character and his intuitive judgment. He reasons that the ore lying at and about the center of a block or section of a vein, exposed on three or four sides, will probably partake, to a great extent, of the character of the vein where it is exposed in the workings. If these have shown the vein to be fairly regular in size and value, he is willing to admit the probability of the center of the block, if not too large, being of similar character; but if the actual workings have proven the vein to be erratic in both size and value, his natural inference is that the center of that particular block will not prove an exception, and found to be richer or more extensive than the portions of the vein already exposed. Even approximate estimates can not be ventured where the workings are long distances apart; but if levels be not over 75 to 100 feet apart and raises not over 60 to 100 feet apart, an estimate based on information obtained in the manner described is not likely to prove very misleading. In every examination of a large mine the values of the property, as determined by samples taken by hand and worked down mechanically and systematically for assay, should be proven by mill runs or shipments to reduction works, and previous shipments of ore, mill runs, samples and assays taken by others, etc., all have a bearing on the subject, and, where available, should be examined and given the consideration which they seem to deserve.

THAT granite is technically as well as actually mineral was decided by the United States Supreme Court on the 23d inst., in the case of the Northern Pacific Railroad vs. J. A. Soderberg. Defendant had been quarrying granite from a quarter section of land claimed by the railroad company, who sought to enjoin him. Defendant claimed the land to be mineral, and therefore reserved from the railroad grant. In this the Supreme Court agrees, holding that the land is mineral within the meaning of the law.

It is said that, unless the necessary native labor can be obtained, "it will be impossible to work the Rand mines to advantage," which simply means that the mine managers are unwilling to pay to white laborers a wage rate which would prove an inducement to them, for the reason that the mines can not afford the increased expense. Recently white labor has been in excess of native labor on the Rand owing to the great difficulty experienced in obtaining Kaffirs.

WITH copper between 13 and 14 cents there are large profits for most of the greater concerns, and also for many small ones. Moreover, that price is not prohibitory, and does not create unusual competition with other metals as substitutes for copper.

CONCENTRATES.

FIVE HUNDRED GRAMS OF OIL (1 1/2 pound) produce an energy of one mechanical horse-power. This would equal in continuous effect the efforts of twenty-one men.

A FRAMER is a machine which every mine timber shed could use where power is available. It is more economical than framing timbers by hand, and its work is as accurate.

"CRUSHED STEEL" is an artificial abrasiyo, used more particularly by stone cutters. One company in Pittsburg, Pa., produces nearly 700,000 pounds crushed steel annually.

THE laws of several mining States require that a code of signals shall be conspicuously posted at the station of each level in the mine as well as at the collar of the shaft and in the engine room.

IN the best coke the moisture should not exceed 1 1/2%; the volatile matter should not exceed 3 1/2%; the fixed carbon should be above 86%; the sulphur should not exceed .75%; the ash may range from 5% to 11%.

THE CALUMET & HECLA copper mine at Houghton, Michigan, has twenty-eight heads of steam stamps, with a daily crushing capacity of 8000 tons of ore. The copper occurs native in the rock and is recovered by concentration.

IN answer to a California inquiry, the laws of the State provide that a corporation may pay dividends to its stockholders from the net earnings of such corporation, but any dividends paid not obtained from net earnings are illegal.

A MACHINE DRILL may be mounted on timbers and used as a trip hammer in the blacksmith shop. Supplied with a suitable pestle, it is useful in pulverizing mine samples. Two pounds of rock can be pulverized to pass a 20 screen in about two or three minutes.

MINERALS can be determined by means of the blow pipe with certainty, but the process requires considerable technical knowledge and practical experience. Both hornblende and augite have distinct cleavage, but it is not usually observable without the aid of the microscope.

THE best indication for oil is a seepage of oil from an oil-bearing stratum, but such stratum is frequently not profitable to bore near its outcrop, as the volatile portion has usually long since passed off, and the residual material is more like bitumen or asphaltum, and will not flow readily.

CINNABAR usually occurs at or near the contact of sandstone and serpentine. This applies to all the large known deposits in the world, though there are numerous occurrences of cinnabar under other conditions, but they are of local importance, and have never been demonstrated to be of great value.

GREAT BRITAIN'S ANNUAL COAL YIELD is about 230,000,000 tons; that of the United States about 250,000,000. The annual coal yield of the entire world is about 750,000,000 tons. Russia is the largest annual producer of petroleum, about 10,000,000 tons; the United States second, about 8,000,000 tons.

THE presence of grit in crude oil can readily be detected by pouring a small quantity of the oil on a pane of window glass. Holding the glass at an angle, the oil will spread over the surface and the particles of grit, if present, will appear as more or less numerous specks on the sheet of glass, and can be plainly seen.

MANGANESE PIG or manganiferous iron is an ordinary iron made from ore containing somewhat more manganese than regular foundry iron, running from .8% to 3.5% in manganese, which neutralizes the effect of sulphur, removes excess of gas, and prevents blowholes. Spiegel iron is used mostly in steel making, containing from 3% to 20% manganese.

THE difference between German slow-burning powder and English black powder is mechanical and not chemical. In the English powder the ingredients are very finely ground, intimately mixed and pressed into one homogeneous mass. In the German powder the sulphur and charcoal are finely ground and intimately mixed, but the oxygen-bearing salt, the nitrate of potash, is distinctly granular.

THE price of water per miner's inch in California varies from 10 to 20 cents per twenty-four hour day. An inch as established by the Legislature of California is 1 1/2 cubic foot per minute. The amount of power that may be obtained from a given volume of water depends upon the height of the column of water (head) above the wheel from which the power is derived. If the power required is variable, and when little is being consumed, the pressure box overflows, build a reservoir or large tank to catch it. By this means a smaller quantity of

water—fewer miner's inches—may be made to accomplish the work, as when little power is being consumed the reservoir partially fills, and when the maximum power is required the additional amount of water is supplied by the reservoir.

CHALCOPYRITE and iron pyrites look alike and are near each other in specific gravity, so that it would be hard to detect either by its weight; but in hardness iron pyrites is away up, being 6, while chalcopyrite is 3.5 to 4. Thus, iron pyrites will scratch glass and easily scratch chalcopyrite, but chalcopyrite will make no mark whatever on iron pyrite. Graphite and molybdenite look and feel alike, both being equally soft, yet one can easily detect the molybdenite specimen, as its gravity is 4.7, while graphite is but 2.2.

A "WING DAM" does not extend entirely across a stream, but from one bank outward a greater or less distance, and thence along and parallel with the bank. In some cases the lower end is left open, and the water impounded behind the dam flows away owing to the grade. In other cases the lower end is closed and the water behind the dam is pumped or siphoned out. This leaves that portion of the bed of the stream comparatively dry, and it may be mined, or stone or other structures may be built on bedrock.

TWO OR MORE locators owning adjoining claims may unite their interests and perform all the assessment work on one of them, if it is apparent that the work thus performed is of advantage to all. But where two or more persons locate a single claim, and decide to divide it into equal parts, each owner to take a certain part of the claim, assessment work must then be done to the extent of \$100 on each part of the claim the same as though each fractional portion were a full claim. In this case there has been a severing of community interest and each parcel constitutes a separate claim.

THE percentage of gold that may be saved by amalgamation in a stamp mill depends upon so many things that it is impossible to even suggest a probable amount. In so-called "free milling" ores 80% of the gold actually free and susceptible to amalgamation by ordinary methods is a good saving—some do better—the escaping 20% yielding a considerable portion to subsequent concentration. In some California mills, where ore is worth \$12 to \$15 as it comes from the mine and sulphides worth \$125 per ton, tailings run \$1.25 or thereabouts. When the value of the ore is lower the tailings are correspondingly lower.

ROCK MASSES in close proximity to veins have a tendency to move, the direction of movement being determined by the line of least resistance. These rock masses are in wedge shape or in the form of lenses, and the unequal pressure results in forcing certain of these wedges from their natural position. The laws of gravity tend to make them fall into the slope of the mine, but the stulls or other timbers resist this, and as a result the rock moves laterally, along the course of the vein. To meet this stulls or sets may be put in at a slight angle to the direction of thrust and in a measure overcome this tendency.

THE hardness and weight of a mineral frequently aids in determining its character. A specimen of cuprite (red oxide of copper) weighs heavy, its gravity being 6. A specimen of cinnabar (mercury sulphide) is 8 in point of gravity. Both of these minerals often look alike, but the difference of two points in density—two points being easily noticeable—will determine the specimen's real character. Its hardness is another easy test. The cinnabar specimen is very soft—it is but 2 to 2.5; but the cuprite specimen is considerably harder, being 3.5 to 4—that is, cinnabar can be scratched with one's finger nail, while it takes the blade of a knife to make a scratch on cuprite.

THE black coating often found on nuggets of placer gold is due to iron or manganese, or both. This is deposited on the gold when the materials lying in the bed of the stream have ceased moving and become cemented slightly by iron and other substances. Such a coating would not form in a stream where upon the occurrence of a freshet the gravel and gold would move down stream. The abrasions to which the gold must necessarily be subjected under such conditions would quickly remove the film of iron from the nugget. Some nuggets that are bright will not amalgamate. These are usually covered with a film of silica or some other substance that cannot be seen without high magnifying power.

AT 100 pounds gauge pressure steam weighs .264 pound per cubic foot. In the case of a duplex direct-acting, triple-expansion engine, steam, when superheated 125° F., will do 16% more work than when saturated. With steam so superheated and the feed water passed through an exhaust heater, a given amount of fuel will produce 10% more work. The duty of a reheater is the sum of two distinct actions—the drying of wet steam and superheating of the steam thus dried. For the first, it must be competent to supply the amount of heat per unit weight. The area of heating surface and the temperature-head producing flow into the drying stream, as it passes into and through the reheater, must be sufficient to furnish this amount and also the quantity per unit weight re-

quired to insure the demanded superheat for each unit weight of steam flowing through the reheater. The use of perfectly dry steam and the elimination of condensed water would seem a very practical advantage of superheating. Water is a disturbing element in steam engines and steam pipes at all times. It increases the friction of the wearing surface, interferes with the lubrication, and chokes up the discharge; it produces unequal strains in the metal, due to different temperatures, and often gives leaks at joints which remain perfectly tight under dry steam.

SWELLING GROUND may be troublesome from only one side of the workings. In some drift mines this character of ground is often found in the bedrock, and then drifts or main gangways run in this rock prove expensive and difficult to maintain. In quartz mines, where the rocks swell upon being exposed to the atmosphere, either foot or hanging wall or both may swell, and sometimes also the vein material swells when the fissure is not composed of quartz. When this tendency to swell is noticed on all sides, it is almost impossible to keep the drift, shaft or other cutting open, and wherever possible it is more economical to abandon this development and make a lateral drift in the hard wall at a distance from the vein.

ANNUAL assessment work may be done on a patented claim, and may be applied to unpatented claims in the group if the work so done is for the actual benefit and development of the unpatented claim. The claims of the group must adjoin, and there must be no doubt of the character of the advantage derived by the unpatented claim in having the work done on the patented claim. Where this is done, or in any case where the work is done at a single point for the benefit of a group of claims, the burden of proof is on the owner to show that the work done, or improvement made, does, as a matter of fact, tend to the development of the property as a whole, and that such work is a part of the general scheme of improvement. This applies to either quartz or placer locations.

AS HAS heretofore been explained herein, it is impossible for "Concentrates" to give even an approximate idea of the cost of working a mine without a very comprehensive idea of all the conditions under which the mine must operate. These include geographical position, distance from railroad, cost of timber, water and power, topography, hardness of country rock and ore, size of vein, tunnel or shaft, dry or wet mine, and amount of water to handle, if any, wages of the district, character of ore and probable method of treatment. It is not an easy task to ascertain the cost of such operation when one visits a mine and makes personal inspection, and it is impossible to do so with no knowledge of the property and surroundings other than the size of vein and reported value of the ore.

THE idea of utilizing the flushing water instead of the boring rod for conveying motive power to the boring rod in rock drilling for deep holes has been put in practice in a hydraulic motor for such boring by Pruszkowski of Frankfort, Germany. The rods are either standstill or raised and lowered or turned, the actual boring being done by a hydraulic motor attached to the bottom of the rods, the water under pressure fed through the hollow rod to the motor, the escape water doing the flushing. In a drilling test with a drive pipe and piston 2 inches diameter, working pressure 170 pounds, the motor gave twelve strokes per second, consuming 1.1 gallons of water, the 8-inch bit drilling through extremely hard sandstone at the rate of 26 inches per hour; in soft sandstone at the rate of 23 feet per hour.

A COMPRESSED AIR haulage plant is and has been in operation at the Red Point drift mine, near Damascus, Placer county, Cal., for several years past. The motor operates under an initial pressure of 700 pounds per square inch. When first introduced the train was controlled on the outward trip by air brakes; but owing to the heavy grades, notwithstanding the numerous sharp reverse curves, it was found that it required as much air to control a train with this type of brake as was needed to pull the empty train into the mine, and the air brakes were discarded and hand brakes similar to the ordinary railway brake put in. These are manipulated by means of a stout, short stick to give greater leverage, in the hands of the trainmen. There is a relay station inside the mine several miles from the mouth of the tunnel, where the motor is recharged.

THE term "apex" or "top" of a vein, according to the Standard dictionary, means "highest point of a stratum, as a seam of coal." The Century dictionary says: "In geology, the top of an anticlinal fold of stratum. The term as used in the United States Revised Statutes has been the occasion of much litigation. It is supposed to mean something nearly equivalent to outcrop; but precisely in what it differs from outcrop has not been, neither does it seem capable of being, distinctly made out." Webster's dictionary defines it as "the tip, point or summit of anything." There are numerous other definitions, all more or less similar, but it will probably be a matter of dispute as long as the "extralateral" right forms a portion of the United States mining law. A good miners' definition would be: "The apex is the point from the foot wall to the hanging wall at the top of the lode nearest the surface."

Boring the Tundra of the Nome Gold Fields in Search of Gold.

Written for the MINING AND SCIENTIFIC PRESS by OTTO HALLA.

Since the discovery of gold on the Nome beach, this question was always open for discussion: "Does the tundra between the Bering sea and the hillsides contain gold in paying quantities?"

During the winter of 1899-1900 several shafts were commenced at the edge of the beach on the tundra, but owing to the frozen condition of the soil the work of picking the ground was very tedious, and wood too scarce to "burn down," the result was that in many instances work was abandoned before bedrock was reached.

In the winter of 1900-1 better conditions prevailed, a number of boilers being brought in during the rush of the stampede, and winter work, especially thawing, was done in a limited way, owing to the high price of coal. It was sold in the town of Nome that winter at \$75 or more per ton, the delivery to any claim would advance it about \$25 more, so that very few mine owners could avail themselves of the opportunity of working their claims that winter.

In many instances it was found, however, that there are places in the tundra not frozen, and those were found in the vicinity of growing willows. Some very good paying ground has been developed in those spots, so that it became the prevailing idea that the pay is found in the spots not frozen, or "open" spots. Invariably, however, when the shaft went to any depth, water was struck and the work had to be abandoned.

During the winter of 1901-2 more work was commenced in sinking shafts, this time under more favorable conditions—the coal at \$35 per ton and labor plentiful. Several shafts were dug to bedrock and the result was very satisfactory in proving that there are several layers of paying gravel, varying in thickness from 6 inches to 3 feet, and in some places as high as 20 feet of pay.

The depth differed in many localities from 65 to 120 feet to bedrock. The shafts were sunk at considerable distances apart, and any discovery of gold may, as far as could be told, have been only local, (for that particular claim). It was left to the boring machines to ascertain the true condition of the tundra in divers places. These have demonstrated beyond doubt that the deposits accumulated between the hillsides and the Bering sea contain large amounts of auriferous gravel, the value of which, computed by the cubic yard, reaches into the millions. An 8-inch oil well boring apparatus was used, the easy transportation of the machinery over the snow covered ground enabled the systematic prospecting of a large area of the tundra. It was found, as in the shafts, that several paystreaks varying in thickness overlay each other with a strata of clay, or muck, or in many instances beach sand between, the whole reaching to a depth of 65 to 120 and even 130 feet. It was conclusively proven that the same conditions prevail on the tundra as on the beach, which is, that the action of the sea has concentrated the gold in streaks parallel to the beach, varying in values at different depths.

The boring machine, of course, is only the forerunner of the actual work—the prospecting of the ground—the real work of which has to be done by sinking shafts and drifting on the different strata with thawers, the frozen condition of the ground making the work similar to quartz mining. The costs will be confined to thawing and hoisting of the pay gravel. Timbering can be entirely dispensed with, except in the "open" spots, which undoubtedly will necessitate pumping machinery to keep the shaft dry. The first condition of success to make the workings profitable is cheap coal. As long as the coal is sold in Nome at the extortionate price of \$35 to \$40 per ton, as at present, the development of the deep ground will be indefinitely retarded, and were it not for the experiments with the boring machines, there would have been up to the present time no light thrown upon the conditions of the tundra.

There is room for a hundred boring outfits in Nome. The work done by a few of these machines on the high benches of Dexter creek in prospecting to a depth of 120 feet is an immense saving of labor upon the old system of shaft sinking; moreover, the ground is being systematically prospected. An entire season's work is spent in many instances in sinking a shaft, for the purpose of testing the ground. If the result is negative, the ground is usually abandoned on the test of a single shaft, whereas the machine, by boring holes in two or three days, proves up the ground and indicates where a shaft can be sunk to obtain the best results. There is no need of waiting for winter season to prospect with boring apparatus. The past summer season's work was done on Anvil and Dexter benches uninterruptedly. But to bring them into general use, the price of coal must be much lower than it is now; with coal at \$15 to \$17.50 per ton, everybody could avail themselves of the opportunity to prospect, but at \$35 to \$40 per ton only mine owners who have prospected their ground can afford to work it during the winter season. There is an opportunity for enterprising men, with capital, to bore and prospect ground for

an interest in the claims, or to bore at so much per hole. Where miners individually could not afford to buy the entire outfit, many would be glad to pay for the prospecting of their claims.

The present winter season will add a great deal to our knowledge of the tundra and benches, as there is much work being done everywhere in the vicinity of Nome, but there is no question that the boring machine will be a great factor in the discovery and tracing of the strata of gold-bearing gravels in the Nome gold fields.

Nome, Alaska, Nov. 24, 1902.

Experiences of a Working Miner.

Written for the MINING AND SCIENTIFIC PRESS.

Very few mining engineers are "horn great." They usually have to work hard and for a long time before their services receive that substantial recognition which in these days is considered commensurate compensation for technical training and years of practical experience. An engineer of my acquaintance, who to-day occupies an enviable position in the mining world, tells this experience of the early days of his career:

"It was back in the early '80s. J— was operating and endeavoring to negotiate some 'hum' claims on P— Mt. He engaged me for \$50 to make surveys and plans of the claims—both surface and underground. I turned in my work, and old J— said:

"'But where's the report?'"

"'What report?'" says I.

"'Your report on the mines,'" says he.

"I had done all sorts of 'scrub' work, assaying, drafting, surveying, etc.; but no one so far had even hinted that my opinion of any mine was worth anything. My chest bulged out a few inches, but I managed to explain calmly that 'surveying' was one thing and 'mine examining' quite another. Evidently I convinced J—, for he told me to make the report and he would pay me 'whatever it was worth.' That was the report of my life. The mines did not admit of much, but I started in and curled up a little Earth from a nebulous toss-off of the solar system. I precipitated earth-making material and washed it with ages of rain. I stratified it, upheaved it, faulted and fissured it. I mineralized the fissures, and, finally, I got down to local conditions—the mountain backbone of the American continent—thence by gradations to the State of N—, where I described the great mining districts of the State, finally reaching E—; here I described the C— and R—; at last I crept up the trail to P— Mt., had my say about J—'s properties in about three paragraphs and the brain fog was over. Then came a day or two of corrections; finally a fair copy was made and handed to J—. I fancy there must have been fifty pages at least. J— read it over attentively and wrote out a check for \$55—\$50 for the survey and \$5 for the report. I did not appreciate the joke at the time and only thought that J— did not know any better. It did not dawn upon me that it was a fair estimate of 'what it was worth.'"

The L— W— Company bought a good prospect in A—, and, after developing it somewhat, decided that the mine justified reduction works of some kind; but it was a question what kind was most desirable. One director wanted a stamp mill; another had heard that rolls were superior to stamps; a third would listen to neither, but insisted on a smelter, urging that it cost less than a mill of equal capacity, required less water (and water was not abundant), and, as he was a man of force, he carried the day, and all the members of the board agreed that, after all, a smelter would be best, as it would turn out a high grade of product in quantity. A smelter was bought and set up and a man engaged to run it. This last party was an old smelter hand—had pushed slag pots, helped around a converter and knew the business from Alpha to Omega.

The ore was white quartz with iron sulphide and a little zinc or copper occasionally. The sulphides did not exceed 10%, but the values were fair. An experienced man would have recommended a stamp mill and concentrators as probably best suited to the conditions.

The smelter man could not manage the smelter, and finally admitted he was a "copper smelter, anyhow," and, on the advice of some friends, an experienced smelter superintendent was engaged. He visited the mine, examined the ore and said at once that a mill and not a smelter was wanted. The owners insisted on his trying the furnace. There were neither limestone nor iron within 50 miles of the place and coke was high—about \$25 per ton—and he did not even consent to attempt to run the furnace. After more discussion and getting advice (for which they paid), the loss of a year's time and with a second-hand smelter on hand, these mining men agreed, as they knew nothing of mining, to retire from the management and place a competent man in charge of the property. He promptly asked for \$30,000, which was placed in bank. A modern mill now stands on the mine, and a steady stream of hulkion is coming from the mill—all because of competent management.

The Theory of Misfires.*

In a discussion of a paper by E. H. Weiskopf, at a meeting of the Chemical and Metallurgical Society of South Africa, James Thomas said:

I have been going carefully through Mr. Weiskopf's paper in order to find the theory of misfires, as suggested by the title of his paper. The only suggestion of a "theory" that I can find, however, is that misfires are due, either to using too weak a detonator, or to the insensitiveness of the explosive.

In my experience, by far the greatest number of fires arise from:

- (1) Bad and cheap safety fuse.
- (2) Carelessness in handling safety fuse.
- (3) Carelessness in fixing on the detonators.
- (4) Detonators not cleaned out.
- (5) Low class detonator and insensitive explosive.
- (6) Carelessness generally.

(1) Cheap Fuse.—I have had twenty years' experience in the manufacture of safety fuse, and I know that a good reliable safety fuse cannot be sold in Johannesburg at the prices at which it is being offered by some firms and yet leave a profit.

It must be evident that to sell at such prices must either mean: 1. A quality less reliable than that manufactured under profitable conditions, which would naturally ensure greater care; 2. That manufacturers are sacrificing profit meanwhile in order to gain a footing for other goods.

Until some measures are enforced to secure a reliable quality, and so long as the percentage of misfires is not too great, the fuse will probably be considered by some as good enough. In my opinion this is a great mistake, for where men's lives are at stake nothing but that which is above suspicion should be used.

(2) Carelessness in handling the safety fuse.—Miners, as a rule, if they are going to charge any number of holes, cut the number of pieces of safety fuse into the lengths required, and then place them somewhere, until each in turn is wanted. Should, however, under these circumstances, the small column of powder at the ends touch the least damp, it will not convey sufficient fire to ignite the detonator.

(3) Carelessness in fixing the detonator on the fuse.—It is possible in wet ground for the outer layer of cotton to act as a channel to convey water into the cap. This has been known to be the case where proper care has not been taken against its possibility.

(4) Detonators not properly cleaned out.—This I have known to be the case many times; I had such an experience only a week or two ago. The detonator had passed through the hands of two miners, two holes were fired, but only one exploded, and on examination afterwards it was found that the detonator still contained sawdust.

(5) Low class detonator.—Sometimes, as pointed out by Mr. Weiskopf, the detonator is at fault. With detonators of the cheaper kinds, not uniform in strength, and with detonators too weak, also with insensitive explosives, misfires do, no doubt, sometimes occur, and I think that in the majority of cases partial misfires may be expected.

I am a believer in the old-time primer being used to assist in detonating the main body of the charge.

(6) Carelessness generally.—I am afraid that too often miners at work give little heed to what may be termed "little things," and a confession I often hear is: "Well, men will not take the trouble."

One of the greatest dangers that we have to guard against is, in my opinion, partial misfires, caused sometimes by badly incorporated mixtures; also in the case of blasting gelatine by too large a percentage of collodion cotton, and sometimes by the detonator being under charged. Thus parts of charges are left in the hole, and then attempts are made to deepen the holes, with the result that at the first blow an explosion occurs and those near are killed or injured.

Boring in old holes is responsible for by far the greater proportion of accidents with explosives that occur on the Rand.

Just a word as to the treatment recommended by Mr. Weiskopf of a man gassed by nitrous fumes. No doubt the treatment is theoretically good, but I may say that I know of a factory where a few drops of ammonia in water were given to men so gassed, and oxygen was inhaled for about five minutes, after which they completely recovered and returned to their work.

J. Watson, continuing the discussion, said: When a misfire has taken place, through what thickness of tamping or stemming, is it practicable to explode the original charge by inserting a fresh cartridge, with detonator, fuse and additional tamping?

Some three or four years ago I learned from a Transvaal mine manager that 14 inches of tamping is about the maximum amount through which the original charge can be exploded, and from my own experience I have no reason to doubt the accuracy of this statement.

The withdrawal, or unramming, of tamping from a hole which has missed fire is a dangerous operation; but by limiting the depth of tamping to 10, 12 or 14 inches (which is surely sufficient to give an effective

*Journal Chemical and Metallurgical Society, South Africa.

shot), it is a simple matter for the miner or prospector (who has had the misfortune to have a misfire), after waiting the regulation period of thirty minutes, to insert another cartridge and explode the original charge.

Practical Application of Dr. Black's Permanganate Process.

Written for the MINING AND SCIENTIFIC PRESS by
D. F. MEIKLEJOHN, E. M.

The recovery of gold remaining in tailings from the various chlorination works in California has long proven a vexing problem to the metallurgist. Many processes have been tried on this material with a view of recovering a portion of this gold, but without success.

The cyanide process has been tried by many experts, and several plants have been erected at the large dump at Sutter Creek in Amador county, Cal. None of these plants ever succeeded in making even a partial saving. The average value of these tailings, estimated from 100 samples taken from ten different dumps, is about \$9.60. The gold might be said to occur in four distinct forms: First, as free

of plant, price paid for the tailings, labor, etc., is less than \$2 per ton.

The plant used consists of one 500-gallon solution tank, two 5-ton leaching tanks, two 600-gallon precipitating tanks, and one copper tank filled with old iron. The leaching tanks are provided with the ordinary gravel filter bottoms, with a 3-inch space underneath. The leaching tanks are charged each with five tons of tailings, which are packed in as tightly as possible by walking around the inside circumference of the tank. This packing is one of the most necessary features of the process. When the tailings are packed tightly the replacement of one solution by another is absolute. The point when the solution ceases is as marked as when the first solution appears. After the charge in each tank is packed and leveled a wash solution, containing one-half ounce of sulphuric acid per gallon of water is carefully sprayed over the ore until the charge is wet for about 6 inches below the top, after which it is allowed to run on as rapidly as possible until each tank has received 500 gallons.

After the acid wash has disappeared 300 gallons of pure water are run through to complete the cleaning. The office of the wash water is to remove all traces of iron sulphate and as much copper as possible. The iron sulphate if not removed reacts on the solution, causing a destruction of the permanganate

twelve hours, the remainder will remain in suspension several days. In order to recover all the gold without a large filter bed, or great number of settling tanks, we use a saturated solution of barium chloride. After the solution has been thoroughly precipitated and allowed to stand quietly for eight hours, a gallon of the barium chloride solution is carefully sprayed over the top. The barium chloride reacts with free sulphuric acid in the solution, forming a dense white precipitate of barium sulphate, which settles rapidly, carrying with it all the fine suspended gold.

After the solutions receive the barium chloride treatment they are allowed to stand quietly for eight hours longer, and are then decanted by means of a floating hose into the copper tank through a charcoal filter. The copper tank is large and is filled with old iron, which removes most of the copper from the solution, and also recovers some gold. The overflow from this tank passes through another charcoal filter, passes over more iron in sluice boxes, and is then discarded.

The precipitation tanks are cleaned up every day, the precipitation transferred to a barrel, which is siphoned off from time to time, until the accumulation is large enough to warrant its being cleaned up. The accumulated precipitate is treated in the same manner as ordinary cyanide slimes, dried and melted.

The successful application of this process is dependent on extreme care, careful watching and thorough washing of the ore. Its use on sulphides carrying, besides the gold, a tolerably high percentage of copper, can be highly recommended. On high-grade sulphurets properly roasted I find it superior in many ways to other chlorination methods. It gives higher extraction at much lower cost, and without any suggestion of free chlorine in manipulation. The extraordinary simplicity of the method, its cheapness, its freedom from free gas and its possibilities should recommend it to all interested in modern leaching processes.

Sierra City, Cal., Feb. 20.

Permanganate Plant
at
Sierra City Cal.

gold very fine and light; second, gold that was once in chloride form, but which was not thoroughly washed out; third, gold encased in small, partially fused particles, due to imperfect roasting; fourth, gold intimately associated with iron oxide, probably in combination.

The gold that occurs in the first two forms is easily recovered, that in the third and fourth forms is lost in the tailings.

A small saving can be made by passing the tailings through a form of spitzkasten and concentrating the coarse lumps, which are usually rich enough for smelting.

In September, 1900, I began a series of experiments on chlorination tailings, working merely on the supposition that they would yield to some application of the cyanide process. I made many cyanide tests, all of which were failures so far as practical work was concerned. I spent two months in Denver, Colo., at one of the best laboratories there trying every known form of cyaniding, amalgamation or concentration, with negative results.

In April, 1901, there was published in the MINING AND SCIENTIFIC PRESS an article by H. Norman, describing "Prof. Black's Permanganate Process."

I was at once struck with the possibilities of this process, and arranged for a series of tests. The first few tests were failures, as I made the solution too strong. The first dilute solution I used gave 40% extraction. After about four months' work with this method I was able to extract and recover 50% of the gold remaining in chlorination tailings at a cost of about 30 cents a ton for chemicals.

The recovery of the gold after it was in solution proved almost as difficult as getting it into solution. In all this work I was assisted by A. H. Stephens, an electrical engineer, who is also a thorough chemist. When we at last determined to make a practical trial of this process we purchased a small pile of chlorination tailings from the Sierra Buttes Co. at Sierra City, Cal., and a small cyanide plant. We arranged the cyanide plant to use the permanganate process as we had determined it, and began work in November, 1902. Up to the time of this writing we have run through 400 tons, which have yielded \$6.10 per ton.

The total cost of working, including chemicals, cost

and a partial precipitation of the gold. The reactions are approximately as follows:

and—

To hasten the washing of the ore a suction pump is used. The ordinary form of ejector answers very well where a good force of water is obtainable. After the ore in the tank has been dried with the vacuum pump it is again carefully packed around the edges and the leaching solution run on as rapidly as possible. This solution is made up as follows: $7\frac{1}{2}$ to 10 pounds crude sulphuric acid, 10 pounds common salt (Na Cl), 10 ounces of potassium permanganate to each 100 gallons of water, 100 gallons of solution being required to each ton of ore.

The solution started from the top of the charge appears in about seven hours at the bottom. And if the ore has been properly washed the solution has a faint pink tint and shows a slight amount of gold. As the color increases the amount of gold increases. The increase is gradual for about four hours, then falls off rapidly toward the last. The solution is given about ten hours contact.

*The reaction that takes place is as follows:

and—

After the solution appears below the charge it is conducted by hose to precipitating tanks, where it receives a strong solution of iron sulphate. When the precipitation of the gold is complete it is allowed to settle for eight hours.

The gold appears as a very fine purplish-black precipitate, which no amount of stirring will accumulate. The extreme fineness of this precipitate makes it difficult to collect. About 60% of it will settle out in

*Taken from MINING AND SCIENTIFIC PRESS, April 6, 1901.

The Depth of the Dolcoath Tin Mine.

The new Williams shaft of the Dolcoath tin mine at Camborne, Cornwall, commenced about seven years ago, would strike the main lode about 300 feet below the deepest working parts of the mine when sunk vertically 3000 feet. This shaft has been sunk half way, and sinking is being carried on at a speed of about 600 feet per year. The deepest working parts at present are about the sump and eastern shafts, where they are about 2400 feet vertically from the surface. The numbers attached to the levels are, perhaps, misleading to those unacquainted with the mine. The so-called 2400-foot level would be 2400 below the adit, measured on the incline of the lode. The adit is over 180 feet from the surface. This gives to the so-called 2400-foot level an inclined depth of over 2580 feet; but vertically measured it would be about 2100 feet from the surface, possibly rather less. Dolcoath is thus practically half a mile deep.—West Briton.

Open Trough Roller Pan Conveyor.

The accompanying illustration shows an endless open trough roller-pan conveyor for handling heavy ore from the bins to the crusher of the Colorado smelter of the Anaconda Copper M. Co., at Ana-

Open Trough Roller Pan Conveyor.

conda, Mont. This conveyor runs in front of a series of bins, from which the material is fed into it by means of special gates. The ore varies from small pieces up to lumps weighing 200 pounds or more.

The conveyor is about 150 feet long, and is constructed of a heavy Hercules chain, designed for heavy work, where gritty or abrasive material is handled. The chain is covered completely with over-

lapping pans, forming an endless open trough. The pans are made of steel, reinforced with oak planking, the latter designed to take the thrust of the pieces as they fall from the bin and the steel the abrasion from the ore. Every other pan at intervals of 2 feet is provided with a heavy steel axle and two 6-inch self-oiling flanged rollers. The conveyor is of heavy construction throughout. These conveyors are built of both light and heavy construction, of different capacities and length to meet local requirements, by the Jeffrey Manufacturing Co. of Columbus, Ohio, who will be pleased to give prices and particulars to any one interested.

Cyaniding Tests at Ely, Nevada.

To THE EDITOR:—A recent article, "Cyaniding Tests at the Chainman Mine, Nevada," contains some statements of a rather positive nature which the writer feels called upon to correct.

Had Mr. Janin, the author of the article, confined himself to the subject matter proper, no cause for dispute could have occurred.

The writer, whose services were obtained to put in operation the new mill of the Chainman Co., the one in question, wishes to give a short description of the method of treatment as finally adopted at the plant, and incidentally to correct an impression that must surely exist, and that places the then manager in a bad light.

To begin with, Mr. Janin quotes a number of tests, made during his sojourn in Ely, and under his personal supervision, on the ores of the Chainman mine.

All of these tests, without exception, so far as the writer knows, were made on extremely small lots of ore—say from five to fifteen assay tons. These tests, while of undoubted value as a preliminary to the large leaching tests, also to be carried out in the laboratory, have aside from this no practical value whatever, as they invariably give faulty results, both in extractions (generally high) and in percentage of cyanide consumption, likewise high. Especially is this true in the case of agitation tests.

The writer, on accepting the position of mill superintendent, was of course called upon to make a large number of metallurgical tests.

It required but a superficial examination to show that the method of treatment settled upon by the previous experimental tests was an impossible policy, based upon carefully prepared average samples obtained from the mine; and here, by the way, it seems essential to call attention to the careless practice, so often followed, of using the samples for determining tests that do not represent a fair mine average. Such a course invariably leads to disaster.

By experimental measurements and careful calculations, it was found that only a slight excess of water over that required to operate the mill on a wet crushing basis, as set forth in Mr. Janin's article, was to be had. All this water, by the way, had to be pumped from the mine shaft to a tank on the hill above the mill, at a heart-breaking expense for fuel and labor, as the pumps required a steam pressure of close to 100 pounds at the boilers, and almost constant attention during the entire twenty-four hours. Furthermore, this water was in such a condition chemically as to render it inadvisable to use it, at least without the use of some neutralizing agent, such as lime, which brings at this distance from the railroad (150 miles) the extreme price of \$26 per ton, and adding to the already high cost of the water another large item of expense.

The writer, therefore, profiting by the known fact that the ore had already been treated with fair success, by methods of dry crushing, a condition mentioned by Mr. Janin in his article, but overlooked by him in his experimental work, made a series of tests on lots of ore varying from five to sixty pounds.

It was the intention to carry out the tests at all meshes, from mine run to 40-mesh wire screen, but the first two tests, one at 1½ and the second at ½-inch mesh, gave results of such an encouraging nature that series of tests were run, meeting a condition similar to that of the first test, with uniformly excellent results.

It was found that without the use of a quantity of lime, at least four and one-half pounds per ton of ore, results showed a decided falling off, both in extraction and in consumption of cyanide.

To show the results of this scheme of treatment on a large scale it is only necessary to quote a few of the summaries on the tanks as operated on the mill. This treatment, by the way, closely resembles the mode of treatment as practiced at the old Mercur mill during the days of the Mercur oxidized zone.

The writer agrees with Mr. Janin, that the ore resembles a tufa, of a decomposed character, but thinks it was originally a sulphide ore, since oxidized and leached of its sulphates, deriving its values from below by ascending mineral solutions, which dissolved out the limestone along the line of contact of the porphyry dike with limestone and replacing the cavities with an ore deposit, and also impregnating the dike alongside. The reason for solution of the limestone along the line of the dike is explained by the alteration of the limestone caused by the intrusion of the dike itself, making it more susceptible by the percolating mineral waters.

There is not an indication of the iron having come from the limestone at any time, and its presence in

the dike in excess of the amount in the vein matter is easily explained by the fact that the dike is of much firmer material and less altered, and consequently less readily oxidized and leached.

The ore as brought from the mine was sent to the top of the mill by the inclined tram, run over a grizzly, set to 1½-inch spread, and the fines, sent direct to the leaching tanks; the balance, ore oversize, amounting to something like 15% of the total, was first passed through an Austin gyratory crusher, set to a 1-inch opening, and then also sent to the leaching tanks.

Here it was treated to a solution varying in strength from .2% for the strong solution, to .05% for the weak solution, five pounds of lime being added per ton of ore to the cars before passing the rock breaker, they thus being thoroughly mixed before coming to the leaching tanks.

The following results on a number of the first tanks treated are presented:

Tank No. 1—	Gold.
Heads.....	\$2 45
Tails.....	83
Tank No. 2—	
Heads.....	3 56
Tails.....	93
Time of treatment, 104 hours.	
Cyanide consumed, 106.5 pounds.	
Tons, 112.5.	
Tank No. 3—	
Heads.....	3 10
Tails.....	62
Time, 150 hours.	
Cyanide consumed, 95 pounds.	
Tank No. 4—	
Heads.....	2 48
Tails.....	83
Tons, 105.	
Time, 150 hours.	
Cyanide consumed, 100 pounds.	
Tank No. 5—	
Heads.....	2 48
Tails.....	83
Tons, 103.	
Time, 150 hours.	
Cyanide consumed, 100 pounds.	
Tank No. 6—	
Heads.....	4 13
Tails.....	93
Tons, 110.	
Time, 120 hours.	
Cyanide consumed, 105 pounds.	

I also quote from two tanks that were allowed to fall below the regular five pounds of lime per ton:

Tank No. 1—	Gold.
Heads.....	\$3 10
Tails.....	1 96
Tons, 107.	
Time, 160 hours.	
Cyanide consumed, 132 pounds.	
Lime, 320 pounds.	
Tank No. 2—	
Heads.....	3 93
Tails.....	2 27
Tons, 109.6.	
Time, 160 hours.	
Cyanide consumed, 155 pounds.	
Lime, 100 pounds.	

Mr. Janin makes the statement that under good management the plant should have been a partial success.

The writer acted merely as the metallurgist and mill superintendent, but he is at a loss to know how a success (he does not know what Mr. Janin means by a partial success) could be accomplished in the cyaniding of an ore that gave, not \$9, \$10 and \$12 per ton, but values of less than \$3.50, on a basis of fifty tons per day, 150 miles from a railroad with hauling rates at 1½ cents per pound, lime at \$26 per ton, and fuel high and scarce.

The writer does not wish to question, or detract from the ability of Mr. Janin in any respect, but feels compelled to alter any false impressions that might be derived from the mere reading of Mr. Janin's article.

There is one other thing that I wish to speak of before dropping the subject. Others may have noticed it, but if so I have never seen it given expression. It is that in many, if not in all, cases a tailings dump which has come from a cyanide plant can not be safely sampled over the surface.

The reason for this is that the action of the sun in drawing the dissolved values to the surface and then evaporating the moisture concentrates the values at that point. This would probably not be the case in the winter after the snow had been standing on a dump for any length of time, sufficiently long for the moisture to carry the values back into the dump and again distribute them, though it is extremely doubtful if even this would occur to any extent.

At any rate, in the majority of cases the dumps are sampled during those months when the other condition exists, and misleading and oftentimes extremely high results are obtained, sometimes causing serious trouble, both by the erection of plants for the purpose of retreatment, or, as is more often the case, injury to the men who originally operated the plant by permanently hurting their reputations, in a manner entirely undeserved.

WINTHROP H. WICKHAM.

Denver, Colo., Feb. 12.

Lead Refining at Trail, B. C.

For many years experiments have been in progress, with the hope of eliminating the fire process in the separation of the values and impurities in lead bullion. This process is hard on those engaged in the work, and the dangerous lead fumes make it impossible for men to continue their vocation longer than three or four years, lead poisoning invariably resulting. According to the Canadian Mining Review, A. G. Betts by his new process is producing electrolytic lead on a commercial scale at the Trail refinery.

The Betts process involves the dissolution of the lead in the bullion, or anode, and its precipitation upon a steel plate, or cathode, by electrolysis. Electrolysis may be defined as the course of chemical changes induced by the passage of a current of electricity through a chemical compound, in solution. The solution, or electrolyte, with the aid of the current, dissolves the lead in the anode and transfers it to the steel plate, leaving the impurities behind as a slime.

The plant consists of twenty-eight cedar vats, well joined, and lined with rubber composition. They are in four rows, seven to a row, and so placed that each vat is 3 inches lower than the one above, in order to permit of the better circulation of the solution. The current is furnished by two dynamos, running in parallel, generating 2000 amperes each, and conveyed to the vats by means of large copper bars. The vats are connected in series, so that the current passes from the first on through the twenty-eight, entering the solution in each vat through the anode and passing out through the cathode. To make the matter clearer, it may be well to state that the electrode by which the current enters the electrolyte is called an anode, and in this case is the base bullion, and that by which it leaves the electrolyte is called a cathode, which in this case is the steel plate.

After the lead ore is treated at the smelter, the resulting bullion, instead of being cast into bars, as it runs from the furnace, is moulded into anodes, 30x40 inches, and an inch in thickness. It is made into this form in order to provide a larger surface for the actions of the acid. These anodes weigh about 350 pounds, and contain, approximately, 3% of impurities, consisting of arsenic, antimony, iron, zinc, silver, gold, bismuth and cadmium. They are carried on a runway and lowered so as to hang perpendicularly in the electrolyte, which is a solution of lead salt. Twenty-two of these anodes are thus suspended, with a steel plate or cathode placed in like manner, between the anodes, at an equal distance of 2 inches. The selective action of the electrolyte dissolves the lead in the anode, and the current of electricity transfers it to the cathode, leaving the foreign substances in place on a mere skeleton or sheet of lead, which remains. The process by which the twenty-two anodes in each vat are dissolved requires about eight days, and in order that the action may be equal on the entire surface of each anode, the electrolyte is kept circulating from one vat to the other, and from the last vat it flows into a collecting tank, whence it is pumped back into each row, thereby maintaining a constant circulation of the solution. When the anodes are about spent, or eaten away by the action of the current, the cathodes are hoisted from the vats and a sheet of lead, 99.999% pure, is stripped from the steel plate and recast into bars for shipment to the manufacturer of lead products. The anodes are then transferred to a separate vat, where the impurities, which have remained as a muddy slime, are washed from the skeleton sheets of lead, which sheets are recast into anodes, to undergo the same process of refining. About 15% of the original anode remains unspent when the slimes are removed. The impurities, or slimes, are of such a nature that they cannot be economically treated on a small scale at Trail, and for the present are being dried, boxed and shipped to the United States, where values are separated and marketed.

The solution used as an electrolyte contains lead fluosilicate and fluosilicic acid. It is prepared at the works by the solution of quartz in hydrofluoric acid, with the subsequent addition of lead carbonate or white lead. The white lead dissolves, with effervescence, to lead fluosilicate. The solution answers very well for an electrolyte, for the lead fluosilicate is very soluble in water. The salt does not crystallize on the sides of the tanks and the solution has no odor, nor is it otherwise disagreeable.

Porcupines Destroying Trees.

To THE EDITOR:—I have made several trips in Montana—in many parts of Madison county, especially on the west fork of the Madison river. The first trip I made I could not help but notice how many pine trees had been killed by having the bark gnawed off. In many places the trees seem to have been nearly girdled. Upon inquiry as to the cause of this, I was told it was the moose which inhabited this vicinity, and from hunger during the winter would eat the bark of these trees; but, upon investigation, I found this was not the cause at all, but, instead, it was the porcupines.

I have seen acres of fine timber land almost entirely destroyed, and on two occasions I saw the porcupines on the trees. It was with surprise I

found out the injury done by these animals, and I fully believe that the State of Montana and other States could not do better than to offer a good bounty for the extermination of these forest-destroying porcupines.

C. O. BARTLETT.

Butte, Mont., Feb. 18.

Mine and Mill of the Ophir Consolidated Mines Co., San Miguel Co., Colo.

Written for the MINING AND SCIENTIFIC PRESS.

The Ophir Consolidated Mines Co., Ophir, San Miguel county, Colorado, is a corporation composed of Wisconsin and Michigan men. The financing of the company is in charge of J. O. Buckley, president, Milwaukee, Wis. The present operations are controlled at Ophir by W. S. Buckley, general manager; H. R. Buckley, assistant manager; J. McWilliams, mine superintendent; C. Nazro, metallurgist, and W. Major, mill superintendent.

The original claims of the company were the Silver Bell and Butler properties, fourteen claims, which they acquired in October, 1900. Up to that time the two properties had produced over \$500,000. There

hin. The ore passes through Challenge feeders to the stamps. From the stamps the pulp went to four Wilfley tables. The tailings from these were elevated by a spiral sand pump to a series of spitzkasten, and from there sent to eight Frue vanners. The crusher was driven by a 20 H. P., three-phase Westinghouse motor, and the hatteries driven by a 30 H. P., three-phase motor. The countershaft for these hatteries was placed below, using belt tighteners. The concentrators were driven by a 20 H. P. motor. In the spring and summer of 1902 the mill was enlarged (see Fig. 1) by the addition of thirty new 1000-pound stamps, batteries of chrome steel throughout, 12 feet of amalgam plates to each battery (see Fig. 2), twelve Frue vanners, a Rohin's belt conveyor 74 feet long with a traveling tripper (see Fig. 3), a sampler, sample conveyor, concentrates conveyor, etc. As the mill is now arranged the ore comes in over the tramway and on to the grizzlies as before, but the feeding floor at the crusher was changed to lessen the labor of feeding.

The ore falls on a belt conveyor which carries it to a Vezin sampler; thence the ore goes to an elevator, and then to the Rohin's belt conveyor, which deposits it in the bins. For the line shaft and lower countershafts was substituted a countershaft giving a horizontal drive to each battery, so arranged that the first battery was driven by a 20 H. P. motor driving

pidity and ease with which it may be carried on.

An auriferous cyanide solution, if made acid with sulphuric acid and hotted with finely divided, pulverulent metallic copper, will, within a short time, deposit its gold content on the copper. Any silver in the solution is also precipitated. If this mixture is now filtered, the filter and contents may at once be subjected to a crucible assay treatment, and its lead buttons cupelled and determined.

If, instead of taking cement copper, or metallic copper powder, a solution of bluestone is used after acidification, and a few small pieces of sheet aluminum are added, and the solution hotted until all the copper has come down, the result as to the precipitation of gold and silver is the same. This modification takes more time and attention in boiling. If aluminum has been used, it should go into the crucible with the filter and its contents. Commercial cement copper is particularly fitted for this test, because the acid, in taking up any basic iron or copper salts of the cement copper, renders the copper as finely divided as it is customary to obtain it in the sluice boxes of "copper leachers." The finer and the more pulverulent the copper is, the greater is its surface and the more energetic the precipitation, thus permitting a minimum amount of copper to be used.

In applying the method, I use, as a rule, 250 c.c.

Fig. 3—Belt Conveyor, Ophir Mill, San Miguel County, Colo.

have since been purchases made by the company until it now owns eighty-two claims, millsites and water rights, all the property lying between the Cariheau on the east and the Butterfly-Terrible on the west, five claims in width. There are five known veins which traverse the property from east to west, nearly $2\frac{1}{2}$ miles, viz: The Silver Bell, Butler, Venticle, No Name and Ida. The latter is a pure gold-bearing vein which runs \$10 and upward. The other veins are large and run in gold, silver and lead, not refractory. The property is located on what is known as Yellow mountain. The sixth level crosscut has approximately a back of 900 feet, and it is estimated that it would take a 100-stamp mill years to work it out. They have a four-drill compressor plant, three drills being run at a distance of 4000 feet from the compressor and 1000 above it, with an average consumption of one ton of coal daily. Machine drills are used for development work, and also in stoping. As a result of two years' work, the company has at this time over 2 miles of levels on ore. Up to date the mine and buildings have cost \$375,000. The property is producing about \$35,000 per month. The mill is situated on the Rio Grande Southern Ry. at Ophir Loop.

This mill, as originally built in 1901, was composed of twenty 1000-pound stamps, with concentrators. The mill contained two 4x8-foot grizzlies, which received the ore from the tramway. The fines from these grizzlies dropped into the ore bin, the oversize going to a 9x15-inch Blake crusher, thence to the

to a countershaft with a Hill clutch-pulley. The other four hatteries are driven in the same manner, excepting that the hatteries are driven in pairs by a 50 H. P. motor to each pair. The horizontal drive to stamp hatteries is illustrated in this mill, where almost all vibration is eliminated with less wear on the cam shaft bearings. The addition of three Hallett classifiers and two Dimmick classifiers have added much to the efficiency of the mill. The concentrates are dumped into a hopper depositing onto a belt conveyor, which elevates them into a bin from which they can be drawn by gravity to the wagons. The mill lies within 100 yards of the railroad station, on level ground, so that tracks can be extended to the mill. The machinery for the mill was furnished by the Mine & Smelter Supply Co. of Denver and the new mill was designed by H. P. Saunders, engineer with the Mine & Smelter Supply Co. L. Felton, of the San Juan, erected the mill.

Test for Precious Metals in Cyanide Solutions.*

By ALBERT ARENTS, Alameda.

This test is based upon the fact that metallic copper will precipitate gold and silver upon its surface from acid solutions. Of course, the fact is not new, but its application is probably so. I have used the method with success; it recommends itself by the ra-

of the solution to be tested; add a few c.c. of sulphuric acid; agitate for several seconds, and then add not less (although not much more) than 1 gram of cement copper. Now follows heating to boiling. This is kept up for about ten minutes, so that the rising steam bubbles keep the mixture well agitated. The mixture is then filtered through a 7-inch-diameter gray filter paper. No washing is done. As soon as the filtering is finished one-third of a crucible charge of flux is added to the filter containing all the sediment of the mixture. Some of the moisture is rapidly absorbed by the flux, which permits the folding of the filter's rim upon the charge and its subsequent removal without loss or tearing. One-third of a crucible charge of flux having previously been placed upon the bottom of the crucible which is to be used for melting, the filter is transferred to the crucible, well tucked down, and the last one-third of the crucible charge is placed on top of the filter in the crucible. It is then ready for the furnace. The filter itself furnishes the reducing agent for the assay. I use 30 grams litharge and the usual amount of borax and soda, employing a No. F crucible for melting. About 20 grams of lead are obtained. The lead button comes out bright and clean, and upon cupelling furnishes a head free from copper.

Possibly this method of testing for gold and silver may be used upon other solutions than cyanide; also, for solutions from testing metallic copper for precious metals, when the solutions do not contain nitric acid in any form.

*Trans. Amer. Inst. Min. Eng.

Transportation at the Grand Central Mine, at Robinson, Utah.

Written for the MINING AND SCIENTIFIC PRESS.

The aerial tramway recently installed at the Grand Central mine at Robinson, Juab county, Utah, shows some new features of construction. Herewith are given several illustrations of this tramway. Figure 1 shows the upper or loading terminal. A 200-ton ore bin is located on the left, next to the shaft house, and the buildings are so located that the ore is trammed only 30 feet from the cage. The floor of this terminal was kept as low as possible to avoid having to raise the head-sheaves of the hoist.

Fig. 2 shows coal hopper and belt conveyor. At the upper terminal there is a coal hopper and belt for conveying coal to the boiler-room. When coal is being brought up an extra man is required, who dumps the buckets into the hopper as they pass him without detaching the buckets or delaying the operation of the tramway. When running full capacity the tramway develops sufficient power to allow every bucket

to be loaded with coal, when ten tons of coal can be delivered into the hopper per hour.

Fig. 3 shows support No. 4, located on the end of a span of about 1000 feet, where the line crosses a deep gully near the mine. This support is built of Oregon fir, the six main posts being 8x8 inches. The ties and diagonal bracing is 3x8 inches, and saddle supports and caps are 4x8 inches and 4x10 inches. This type of support is a radical departure from the usual type of tapering-tower construction with a saddle support across the top. It requires about 25% more material to build a support in this way, but the structure is much stiffer and the trusses are taken care of in a much more economical manner. The legs of this style of support can be cut to fit any kind of surface, and the cost of anchoring them securely is reduced to a minimum. This support is 35 feet high on the low side, and it carries the weight of the long span when the tramway is running loaded on both lines with ore and coal, without showing any signs of weakness.

Fig. 4 gives a view of supports No. 7 and No. 8, which are constructed in the same manner as the higher supports. No. 8 was roofed in to avoid possible contact between the high tension electrical power line which crosses the tramway line at this point.

Fig. 5 shows the lower terminal of the tramway. The railway tracks are in a cut below the surface on the opposite side from view point. The terminal structure is built on top of ore bins that have a storage capacity of 300 tons, which is separated into three 100-ton pockets. The elevated part of the terminal in the rear is the coal elevator.

The coal is unloaded from cars into a bin that has a storage capacity of about three cars. The elevator conveys the coal to a small pocket in the terminal, and it is delivered into the tramway buckets by gravity. The internal arrangements in this terminal for dumping the ore buckets and reloading them with coal is very simple, and when the tramway is not running at a higher speed than twenty tons per hour one man can easily do the work. A new feature about this terminal is the way the side stresses on the ore bins, due to the tension of the cables, are taken care of. Two heavy guys are passed back from the cable anchorages in this terminal to ground anchors, and attached thereto with turnbuckles so that the ore bins are relieved of side strains and have only to bear the working strains due to the loading and unloading of the ore. The material used in all the supports and terminals of the tramway is Oregon fir.

Fig. 6 shows the 5 cubic-foot Bleichert bucket with the friction grip and automatic attacher used on this tramway. There are thirty-two of these buckets in use on this line and they are spaced 324 feet. When the line is operated at the comparatively low speed of 350 feet per minute, it will deliver

Fig. 3—Support No. 4, Lower End of Long Span.

Fig. 4—Supports Nos. 7 and 8, the Latter With Roof.

Fig. 6—Bucket 5 Cubic Feet, With Friction Grip and Automatic Attacher.

Fig. 1—Loading Terminal and Ore Bins.

Fig. 2—Coal Pockets and Belt Conveyors Near Loading Terminal.

Fig. 5—Discharge Terminal.

twenty tons of ore per hour. The new features about this bucket, recently installed for the first time in the territory tributary to Salt Lake City, are the improved grip and automatic attacher. The most commendable feature about these improvements is the comparatively easy way of attaching the buckets to the traction rope. The bucket is attached while it is in motion and will always grip the rope with the grip-lever in the proper position for locking the grip securely, without depending on any muscular effort on the part of the operators other than required to push the bucket into position for gripping the running rope. The shock and necessary slippings in the grip—unavoidable in the old method of snapping the grip down on the rope by hand—is almost entirely done away with in this improvement. Another feature is the absence of the flat spring that passed from the back of the grip and over the top to hold the grip open when detached from the running rope. A round wire, placed on the inside of the grip and giving better service, takes the place of the flat wire.

The difference in the elevation of the loading and discharging terminals is 791 feet, the length of the line is 4575 feet, and when running at the rate of twenty tons per hour develops power enough to carry up ten tons per hour without reducing the speed. When not carrying back freight, all the power developed is absorbed by double brakes in the upper terminal. The standing cables are the locked-coil kind and are connected up in 1000 foot lengths with steel couplings. The cable on the loaded side is 1½-inch diameter, and on the light side 1 inch. The traction rope is ¾-inch diameter and is of the special seven-wire lang lay cast steel kind, made specially for the service demanded in tramway operations.

This tramway was designed for the Grand Central M. Co., and all the material furnished by the Trenton Iron Co., of Trenton, N. J.

Electrolytic Reduction of Lead.

On the subject of the electrolytic reduction of lead, Pedro G. Salom read a very interesting paper at the recent Philadelphia meeting of the American Electrochemical Society. He described the process invented by him and in use by the Electrical Lead Reduction Co. at Niagara Falls. The ores that are reduced are sulphides of lead. They are used as cathodes in an acid electrolyte. The hydrogen ions combine with the sulphur of the ore and form hydrogen sulphide, which escapes as gas, while the lead sulphide is reduced to lead. This is the principle of the process. The apparatus used resembles in a general way a pile of dinner dishes of lead, piled one above the other. Each of these dishes represents a cell, the under side of a "dish" being the anode of the lower cell, the upper side the cathode of the upper cell. With forty-eight cells in series they use 130 volts and get two pounds of lead per horse-power hour.

The lead obtained in this process is in spongy form, and is then used for making other materials, like litharge. Owing to its spongy form the lead is very readily transformed into litharge. Samples of spongy lead, compressed lead, litharge and other materials were shown. In future it is also intended to make accumulator plates.

The principal difficulty in the practical operation of the process was that the reduction was not complete, and that under apparently identical conditions the degree of reduction was not the same, especially as lumps of ore in the immediate neighborhood of the cathode plates were not reduced.

In the discussion which followed, the following explanation of this fact was offered: When the electrol-

At present they have succeeded in improving the reduction so that about 92% to 95% of the lead sulphide is reduced to lead. Another difficulty experienced was that the workmen's eyes were effected during the operation by the escaping gases; but this difficulty appears to have been overcome.

As the developed gases are hydrogen sulphide and oxygen, in their combining proportions, it has been proposed to utilize them in gas engines, which then could develop more power than was used in the process. This apparent paradox was explained by Prof. J. W. Richards in the discussion.

The ores treated in the process contained no silver. No attempt is therefore made to refine the lead for producing silver.—Journal Franklin Institute.

Subway Railroad Construction, Oakland, Cal.

Written for the MINING AND SCIENTIFIC PRESS

Preparations for the new ferry system between Oakland and San Francisco, Cal., by the S. F. O. & S. J. Ry. Co. necessitated crossing the right of way of the S. P. Co. at Yerba Buena avenue, near Emeryville station, Oakland, Alameda county, Cal. To solve this problem a subway is being constructed. The tracks of the S. P. Co. for several miles run parallel with the bay shore, hence the problem of constructing a subway, one-half of which is under tide water, may be deemed of sufficient interest to warrant a description of the method pursued. The subway proper—that portion immediately beneath

Fig. 1—Sheet Piling, Railroad Subway, Oakland, Cal.

the S. P. Co. tracks—is 100 feet long and 18 feet deep, the surface of the concrete in the bottom of the cut being 12 feet below "high water line" and 6 feet below low water. The conduit is 28 feet wide inside on the bottom, allowing space for double tracks. The approaches on either side are 500 feet in length, giving a grade of 3.6%. The bay approach is from the pier, which extends 16,000 feet to deep

(These piles are not to be cut off till the concrete is sufficiently set to hold the posts for the false work.) The tracks of the S. P. Co. will be carried across the subway on a steel plate girder structure, with the ties set in cement in a "steel trough floor."

To build up the concrete sides of the bay end of the conduit, the first step was to drive a row of sheet piling on either side as an outer wall. At the deeper portion 6x12 inch pine was used, and the remainder 4x12-inch. These were made tongue and groove by spiking on strips (see Fig. 1). They were driven into the hardpan to insure a water-tight compartment; and each pile has a double row of 3-inch wrought-iron spikes driven into same, and projecting 1 inch to serve as an anchor for the concrete. The concrete used in the sides and bottom of the conduit will be mixed in the proportions: 20 cubic feet crushed rock, 5 cubic feet sand, 1 barrel cement, the excavation being kept dry during the building up of the concrete by a pumping plant. The bottoms and sides of the conduit are strengthened with old railroad rails laid in the concrete, both longitudinally and transversely (see cut)—those on the bottom lapping 6 inches, and fastened to the cap (2 inch shim between) with railroad spikes. The transverse rails were bent to extend from the bottom up the sides. The concrete on the bottom has sidewalk finish. The walls are to be capped with granite levelers, and the outer sides protected with hand-laid rock, as shown in section. The work is progressing rapidly. All the sheet piling at the bay end has been driven, and the actual work of excavation is about to begin at that end. Meantime the piles are being driven in the soft alluvial at the land end. The work of preparation has now been in progress several months. Fig. 2 represents a vertical cross section of the conduit as it will appear when completed. It shows the details of construction and was taken from the working plans of the engineer in charge of the work, H. C. Holmes of San Francisco, Cal.

Ore Dressing Laboratory at Columbia University.

Laboratory work grows in favor all the time in all kinds of scientific instruction. Text-books are of undoubted value, but the student finds an experiment performed by himself far more impressive than any amount of instruction in words, however clearly presented.

In schools of mining engineering one of the great difficulties which has been met in teaching ore dressing by the laboratory method has been the difficulty of keeping full-sized concentrators in continuous operation for several hours. For example, if a ton of pulp is available for practice work by the students, in a comparatively few minutes it has passed over the vanner, and before the student has had time to really begin the adjustments of the machine he is confronted with the task of pulp shoveling and transportation.

If the student visits mills in full operation he may watch and study machinery in perfect adjustment, but he gains no knowledge of how to make the adjustments that are necessary whenever a new plant is installed.

To make continuous running of full-sized machines possible, H. S. Munroe of Columbia University, New York, has designed an effective laboratory plant. After the crushed ore has been treated on jigs, vanners, tables, hydraulic classifiers and the like, it passes down into a sub-basement, where it enters one of the ordinary mechanical feeding machines, which serves not only as an automatic feeder, but as a small supply reservoir. The material is thence fed into a centrifugal pump, which elevates it back to the upper floor, at the same time thoroughly mixing it. Thus with half a

Fig. 2—Cross-Section Railroad Subway, Oakland, Cal.

ysis begins, the parts of the ore near the electrolyte are reduced; when the electrolysis progresses the current may prefer to pass through the reduced lead to the cathode, hydrogen being developed and no lead sulphide being reduced. According to this view, the efficiency of the reduction would gradually diminish with progressing electrolysis. This would explain the fact that especially lumps of ore remote from the electrolyte are not reduced.

water, where are to be located the ferry slips and depot. In constructing this approach eucalyptus piles were driven to the hardpan, in bents, 8 feet center to center, cut off at the proper grade. On these, fastened with drift bolts, were placed caps of 12x12-inch pine. From each pile an anchor bolt extends up into the concrete. The piles in the subway proper have caps made up of two pieces, 4x18-inch girder planks, let into the piles their full depth.

ton or so of crushed ore any ore classifier may be kept running continuously without attention for any desired length of time. The students first learn the principles underlying ore dressing in a laboratory provided with small tables, glass hydraulic classifiers, etc., that is, they here learn the science of ore dressing. Then, passing into the large ore dressing laboratory, they learn the art of adjusting and handling full-sized classifiers.

Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 17, 1903.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

FURNACE APPARATUS.—No. 720,125; F. H. Foote and T. W. Robinson, Chicago, Ill.

Combination of furnace, ore bin associated with furnace, conveyor constructed and arranged to receive ore from bin and convey same to top of furnace, stove associated with furnace, an offtake flue connected and arranged to conduct combustible gases from top of furnace to lower portion of stove, heating jacket for bin, and connecting flues and passages for conveying products of combustion from stove to jacket.

ORE DISCHARGE FOR JIG TANKS.—No. 720,564; G. T. Cooley, Joplin, Mo.

Combination in ore discharge for jig tanks of compartment extended across discharge end of grate open to upward currents of water through grate, and open at forward bottom edge adjacent to grate for admission of separated ore; barrier in compartment extending across grate and of height equal to desired normal thickness of bed; hutch having mouth full width of discharge compartment and communicating with compartment behind barrier; rotatable pipe mounted in mouth of hutch beyond barrier and partially cut away longitudinally full width of mouth; bottom of hutch sloping toward outside of tank, and faucet adapted to discharge water and ore from hutch.

ZINC SMELTING FURNACE.—No. 720,664; J. P. Cappeau, Joplin, Mo.

Combination with zinc smelting furnace, series of air pipes arranged at intervals at front of furnace, main air passage adjacent to lower ends of air pipes, communicating with them, and open at its ends to outer air, discharge ports in air pipes communicating with interior of furnace adjacent to retorts, gas pipes arranged adjacent to discharge ports, and

means for conveying gas to pipes, whereby air and gas are conveyed and distributed at numerous intervals to furnace adjacent to retorts.

CONCAVE FOR ROCK CRUSHERS.—No. 720,853; J. D. Spargo and G. W. Rose, Doble, Cal.

Combination in rock crusher of shell and separable concaved or grinding surfaces, concaves or surfaces having parallel side edges, and locking keys between adjacent concaves and tapering from one end to other.

AMALGAMATOR.—No. 720,883; O. H. Burden and T. F. Adams, Kaslo, Canada.

Amalgamator, comprising sluiceway having amalgam reservoir, ore attenuating mechanism situated in sluiceway having revoluble members of different sizes disposed in co-operative relation to each other, and means for driving larger of revoluble members at peripheral speed exceeding rate of flow of water and auriferous material through sluiceway.

AUTOMATIC ORE LOADER.—No. 720,960; T. M. Park, Darrington, Wash.

Combination in loading apparatus of tiltable frame, support therefor, sprocket wheels turnable on axes vertical to bottom of trough in which conveyor operates, endless conveyor traveling about sprockets, conveyor having blades adapted to sweep up load at lower end of frame and to discharge load at upper end thereof.

DUMP GATE FOR ENDLESS TROUGH CARRIERS.—No. 720,963; J. Petersen, Chicago, Ill., assignor to the Link Belt Machinery Co., Chicago, Ill.

In trough carrier, combination of permanent track on which is supported one end of each carrier section, with second permanent track having movable sections on which the other end of each carrier section is supported in varying positions at will of operator, both tracks being normally in same plane, and movable track sections being adapted to be moved longitudinally.

ORE ROASTER.—No. 720,969; F. C. Roberts, Philadelphia, Pa.

An ore roasting furnace, consisting of two parallel rectangular structures separated by space, each structure containing series of independent roasting chambers, series of independent combustion chambers and series of independent waste product chambers therefor, chutes for delivering ore to roasting chambers, railway construction for delivery of ore to chutes, second railway in space, and chutes leading roasted ore from roasting chambers to cars on second railway.

FURNACE CHARGING, CONTROLLING AND DISTRIBUTING MECHANISM.—No. 721,088; E. Ramsay and J. J. Shannon, Birmingham, Ala.

In charging structure for metallurgical furnace, combination with main charging hopper structure of distributing box surmounting same, pivotally supported valves or plates in box, and mechanism for swinging valves separately toward center of box to divert material to different parts of hopper, whereby furnace charge may be distributed uniformly in furnace.

SPRING FOR VEHICLES.—No. 721,107; T. G. Stevens, Gravesend, England.

In wheeled vehicle, combination with main frame e, of the horizontal carrying frame d, toggle levers f, g, f', g', pivoted together by pivot spindles, and to carrying frame and main frame by spindles l, l', m, m', toggle levers being all of equal length, body a, mounted on frame d, connecting rod connecting spindles h, i, spring o, rod connecting spindles h, i, with spring, spring box r in which rod can slide, connection between box and main frame, connection between spindle i, and main frame, pointer carried by movable part of mechanism, and scale over which pointer can travel.

Mining Summary.

Specially compiled and reported for the
MINING AND SCIENTIFIC PRESS.

ALASKA.

E. McCannell of Dawson has bought the J. A. Kelsey and S. Parker groups of claims on White Gulch, in the Nizina district, at the head of Chititu.

ARIZONA.

COCHISE COUNTY.

The Copper Glance M. Co., near Bisbee, will put in two 200 H. P. boilers and a pumping plant, the pumps to raise 1,000,000 gallons of water per twenty-four hours.

The El Paso Herald says the Grand Reef mine, owned by the J. W. Mackay estate and located 60 miles north of Willcox, has 12,000 feet of work done on it and that C. Mackay will put up a concentrating plant this spring on the property. The ore carries lead and silver.

The Calumet & Arizona mine reports producing 1,600,000 pounds of fine copper, exclusive of the by-products of gold and silver, for January, with only one stack in commission. The superintendent says the output consisted of 750 tons of blister copper, 99% pure, and 75 tons of matte, 55% pure, besides the by-products. The second furnace was blown in this week and a third will be next month.

The Calumet & Arizona Co., at the Douglas smelter, in December produced 826 tons of copper from a single 250-ton furnace; in January the total output was 837 tons. There were two shut downs during the month. The average of the Calumet is said to be 14%. Additional 300-ton furnaces are being built which are expected to raise the capacity to 125 tons of fine copper daily.

GILA COUNTY.

H. J. Sisty, M. Hotz and M. J. Murphy & Co. will open up the Sultan group of gold mines, near Globe. The incline sunk on the Badger, down 120 feet, will be sunk to 450 feet.

The Old Dominion M. Co. at Globe is planning an outlay of \$400,000 to be used in sinking a new shaft to a depth of 1200 feet and in building a smelting plant and concentrating mill. The smelter will have four furnaces, and a capacity of 1200 tons of ore per day. With these improvements the company estimates it can produce 20,000,000 pounds of copper annually.

GRAHAM COUNTY.

(Special Correspondence).—C. C. Early, J. C. Burnett, J. E. Caplinger et al. have been negotiating the purchase of the Con. Gold Mountain M. Co.'s mines. The new company propose to develop the mines and place machinery on the property. Late development at the mine has opened up new ore bodies which carry gold values in addition to the main ledge, which is 50 feet wide. P. W. Fleming, of Tucson, is secretary. The Gold Mountain property is reported to have produced \$100,000 and has about 2500 feet of development.

Tucson, Feb. 19.

The Arizona Copper Co., near Clifton, has extended its railroad above the Shannon mine and is building additional bins for ore which will be hauled from its Mammoth mine.

MARICOPA COUNTY.

F. Jaeger, president Model M. Co., near Wickenburg, says he will install a complete system of ore roasters, and ten stamps will be added to the 10-stamp mill.

MOHAVE COUNTY.

(Special Correspondence).—The Gold Road mine of the Gold Road M. & D. Co., O. P. Posey president and manager and C. A. Stephens superintendent, is 25 miles from Kingman and about the same distance from Needles. Within two years the company has spent \$125,000 in development and paid for the property. They have blocked out 125,000 tons of gold ore. One vein is 13½ feet and one 16 feet wide in two stopes, and in a third stope is 12 feet. The lower level will average \$25 per ton. They are now installing new hoisting engine, electric pumping plant, etc. Are also retimbering the shaft. The company has built 4 miles of roadway. They are building a 150-ton cyanide mill, which they expect to have completed in ninety days. The power will be supplied by thirteen gasoline engines from 25 to 34 H. P. each; two dynamos for lighting. The water for milling comes from the mine and a pumping plant 4 miles distant.

The Sunbail mine, near Gold Road, is employing a number of men on development work.

The Leland, ½ mile beyond the Snowball, is operated by the Mohave G. M. Co. of Needles, Cal. J. Seward is manager. The tunnel on the Leland No. 2 is in 600

feet, with 30 feet of crosscut. They have a second tunnel in 300 feet. They have a total of eleven claims, eight of them in one group. Ore is free milling. This company will erect a mill.

The Lorona mine adjoins the Leland on the south. A shaft is down 25 feet on 10 inches of high-grade ore, which is shipped. A vein of low-grade ore, which is 3½ feet wide, averages \$12.50. Carl Tanner is manager.

About 4 miles north of the Leland and Snowball is the Silver Creek camp, where the Hardy mine has been worked intermittently for the past forty years. It is now being operated by the Gold Creek M. Co. of Acme, and 2500 feet of work has been done on the property; one shaft is down 225 feet and two 40 feet each; the balance is tunnel work. The company expects to erect a mill. I. W. Hawkins is manager.

The Homestake group of three claims on Silver creek has a shaft and tunnel. The vein is traceable for 2 miles and will average 20 feet wide. R. J. Holmes is the owner.

North of the Homestake is the Yellow Aster, owned by R. E. Zuver. Development is being pushed. They have a good water supply at the Silver Creek or Holmes camp. G. Krauss of Acme is developing the Good Luck mine, near the Holmes.

One of the first claims located in Mohave county, about 2 miles north of the Holmes, is the Moss mine, owned by Burlock & Snyder of Acme. The ledge is nearly 200 feet across. They have run onto an ore shoot 4 feet wide that averages \$21.

Acme, Feb. 22.

(Special Correspondence).—The Night Hawk at Loyna Springs has a tunnel in 1400 feet, which has cut the vein 600 feet in depth. They are cleaning out the tunnel to resume mining.

The Fortunatus mine at Loyna Springs, owned by Dennis & Coffery, has one shaft down 50 feet and another 20 feet. The ore runs three ounces in gold, fifteen to fifty ounces in silver, 30% lead. The Alpha & Omega, owned by the same parties, has a tunnel 300 feet, a shaft connecting with the tunnel 110 feet from the surface. They have a winze 90 feet below the tunnel level.

Kingman, Feb. 23.

(Special Correspondence).—Cerberat, 14 miles north of Kingman, is one of the oldest mining camps in Mohave county. A dozen properties have changed hands there the past two weeks. It is reported that E. T. Loy of Chloride has bought the Cerbat mine and intends reopening it. Denver men have also bought mines in the district and will develop them.

The Frontier G. M. Co., E. F. Holliday, Redlands, Cal., manager, has started work on the Nevada No. 2, Tom, Gusher and Frontier. The work is being done by contract. The Nevada No. 2, down 100 feet, shows a large body of sulphide ore. On each of the other properties they will sink 100 feet deeper.

The Idaho, owned by E. F. Thompson, is down 110 feet and shows \$15 to \$25 ore.

On the Vanderbilt Thompson & Beecher have a shaft 109 feet. Drifting south, they struck 18 inches of ore that will average four ounces gold.

The Golden Gem, owned by the C. O. D. Co., at Stockton Hill, has a shaft 326 feet deep. Drifts run 400 feet north and 150 feet south. The shipping ore averages five ounces in gold, milling ore \$25 per ton. Eight tons concentrate into one. They intend building a concentrating mill. Stockton Hill, Feb. 24.

A half interest in the Ruby group of gold mines, in Greenwood district, 2 miles from the Sandy, was sold last week to J. A. Marshall, of Hackberry.

The Frontier Exploration Co. has incorporated.—J. H. Bohon, E. F. Holliday, E. S. Graham, H. H. Durfee, H. B. Ely, of Redlands, Cal.—to operate near Cerbat.

The Hoffman Co., working the Samoan mine, east of Chloride, are shipping ore to the smelter. The mine is near the top of Sherum's Peak and the ore has to be packed several miles on the burros. It is proposed to build a smelter at Chloride.

PIMA COUNTY.

At the Reward copper mine, near Casa Grande, Superintendent W. P. Guthridge has forty men at work and a 30-ton smelter in operation. The hullion is hauled to Casa Grande for rail transportation. There are twenty claims in the group.

YAVAPAI COUNTY.

(Special Correspondence).—At the Sultana mine, near Hillside station, the new stamp mill and cyanide plant are nearing completion; C. E. Bunker, constructing engineer, and H. La Montague, general manager.

Hillside, Feb. 20.

(Special Correspondence).—The Octave G. M. Co., located at Octave, 10 miles

from the railway, has fifteen claims. Their two working shafts are each about 1200 feet deep, and sinking. The vein averages from 3 to 6 feet in width. Ore is partially free milling. They are crushing 135 tons in a 40-stamp mill. Process, amalgamation, concentration and cyaniding tailings. The mill has been in operation about three years. Air drills are in use and 175 men employed; A. E. Hurley, superintendent.

Octave, Feb. 20.

(Special Correspondence).—The Senate Gold Co., operating the Lucky Day, near the Congress, is down 500 feet, with drifts at the first, second and third levels, on each side from 50 to 150 feet, and body of ore that averages from 4 to 10 feet wide. At the 500-foot level are crosscutting. Ore runs from \$20 to \$25 per ton in gold and is concentrated; J. W. Akers, superintendent.

Congress, Feb. 21.

(Special Correspondence).—The onyx deposits on Big Bug, owned by the Arizona Onyx Co., cover about 285 acres. The company owns 180 acres of this. The onyx (aragonite) is the result of deposit from ancient calcareous springs in the vicinity, the deposit filling the valley several hundred feet across. At the base the aragonite rests on a conglomerate. It occurs in bands of varying width, from the fraction of an inch to a foot or more, the largest and most massive strata being apple green. The quarries have been idle for some time, but it is reported that work is to be resumed.

Mayer, Feb. 22.

(Special Correspondence).—The Bunker Hill Gold Mining Co., operating the Bunker Hill group near Prescott, in the Big Bug district, have a shaft down 100 feet, with high grade pay streak in the hanging wall, 20 inches to 3 feet wide. They are also driving a tunnel at a depth of 700 feet below the shaft.

McCabe, Feb. 24.

The Black Diamond C. M. Co. plant, in the Dragoon mountains near Pearce, is ready for operation and 1000 tons of coke has been contracted for. The company proposes to sink a shaft to a depth of 1000 feet, to strike the sulphide zone. While the Black Diamond Co. has gained a depth of 700 feet in its lower tunnel, below the apex of the outcrop, they say the ledge matter is still an oxide of iron.

The tramway at the Iron King mine, near Jerome, is completed and the machinery for the smelter is being placed.

CALIFORNIA.

AMADOR COUNTY.

Superintendent C. R. Downs of the Bunker Hill mine, near Amador City, reports the mine development as satisfactory. A good vein of pay rock is opened on the 800 level, and a large vein on the 1400. A drift is being run from the shaft to cut this vein on the 1200. He confirms the report that the company will build a 20-stamp mill. The mine is idle at present owing to washout of the Standard Electric Company's ditch.

The tunnel being driven west in the Hoffman mine, near Jackson, is in 460 feet, and in greenstone. One shift of two men are at work, and during January a distance of 70 feet was made, the average cost per foot being \$2.50, says Superintendent J. B. Francis.

BUTTE COUNTY.

W. P. Lynch has bought the Spring Valley mine, at Cherokee. Since hydraulicking was stopped by law it has been worked in a small way under lease. Several months ago the water rights were sold to the Bay Counties Power Co., and work practically stopped. It is reported that the Concow reservoir and water right goes with the property. This will furnish water to run the mine by drifting.

I. Meyer has filed a water right location on Feather river, appropriating 140,000 inches of water, to be taken from the river 6 miles above Oroville, for generating electrical power.

CALAVERAS COUNTY.

It is reported work will be resumed on the Cherokee mine, north of Angels, by San Francisco men.

Manager Morgan of the Sultana M. Co. at Angels says operations will begin by April 1 on an addition of twenty stamps to their mill.

DEL NORTE COUNTY.

J. S. Crawford of Philadelphia, Pa., F. H. Osgood of Seattle, Wash., and associates propose to install a smelter at their Cleopatra copper mines on Diamond creek, near Smith creek, just south of the Oregon line. They will build a railroad from their properties to the coast, 28 miles in length, and will have its terminus at Cable Harbor, Curry county, Or., where they own thirty-five acres frontage.

EL DORADO COUNTY.

Operations at the Baltic mine, Grizzly Flat, will be resumed under bond to a Colorado company.

The Eureka Slate Co., near Placerville, are preparing to put in an aerial tramway 2½ miles long. Water will be the motive power.

A. B. Gould, superintendent of the El Dorado Water Co., has men drifting on their Texas Hill Gravel mine, east of Placerville, and says they struck gravel last week in an upraise.

Neilsen Bros. have bonded the Meder quartz mine, near Grass Valley. They are crushing ten tons per day in a 2-stamp mill.

INYO COUNTY.

The Western Borax Co., W. H. Rees, superintendent, is increasing its working capacity in Saline valley, putting in additional tanks, etc. Two more teams have been put on the road, transporting borax to the railroad at Alvord. They are shipping a carload a week.

KERN COUNTY.

In Kern river field, near Bakersfield, the Monte Cristo Oil Co. has its wells, Nos. 38 and 49, down 700 feet and No. 50 down 50 feet.

The Associated Oil Co. has increased its loading track at the Kern river field to a capacity of fifty cars.

The Alameda Oil Co., near the Diamond at Sunset, has begun work on well No. 2, the derrick is up for No. 3, and lumber on the ground for No. 4.

The Lucky Boy Oil Co. has bought the southeast quarter of section 31 at Sunset from the Pittsburgh Co.

At Randsburg the Butte hill is still attracting attention, \$100 ore being mined in the Butte property, and a new strike of good ore is reported in the Wedge fraction, adjoining it.

LOS ANGELES COUNTY.

A strike of ore is reported in the New York mine, 2 miles from Acton. The ore from this mine and others in the vicinity is a fine grained sugar quartz with finely disseminated sulphurets. The average of ore crushed at the New York, Red Rover and Topeka mines is reported to have been \$12 per ton in gold.

MARIPOSA COUNTY.

H. Soderberg, superintendent Diana group of mines near Bower Cave, near Coulterville, says they will put in a 10-stamp mill. There are seven claims in the group being developed and a body of free-milling gold ore has been opened up.

At the Organita mine, near Mariposa, a gasoline hoist is being put in, the mill is being overhauled and operations will resume next week, says Superintendent R. Dodds.

NEVADA COUNTY.

Superintendent Culp of the Perrin mine, near Grass Valley, says a mill will be built, grading for which will begin next week. The property is being worked by a New York company, of which G. W. Root is president.

C. Puscheck, owner of the Mountain Maid mine, located 12 miles from Nevada City on the Bear river, reports the inclined shaft down 300 feet. Two years ago a new air compressor and machine drills were put in. They have been replaced by a larger compressor and drills. Twenty men are employed and the mill is running steadily.

The Federal Loan mine in Willow valley, near Nevada City, is being unwatered by the Gold Tunnel Co., preparatory to reopening.

PLACER COUNTY.

It is reported the Gold Blossom quartz mine, on Crater hill, in Ophir district, 3 miles from Auburn, will resume next month. R. H. Lloyd of San Francisco is manager.

Manager F. B. Jackson, of Sacramento, says he will work the Fowler & Gallagher placer claims on the American river near Colfax with a dredger, to be installed this spring.

It is reported the Charonnot & Lindley drift mine at Canada Hill, northeast of Westville, is bonded to J. F. Littlefield of San Francisco. A tunnel has been started.

T. H. Wilkins, president the California mine at Shady Run, east of Dutch Flat, says he is putting up a 10-stamp mill at Shady Run, and will crush the quartz and wash the gravel of the mine in the summer.

R. A. Watson, superintendent of the Shady Run mine, near Blue Canyon, says five stamps will be added to their mill equipment.

It is reported the Centennial (Shurtleff) mine, near Ophir, will resume next week. P. L. Lozano, J. L. Grimes and San Francisco men are interested.

SAN BERNARDINO COUNTY.

(Special Correspondence).—Unusual ac-

tivity is noticeable in the vicinity of Oro Grande. In this district are gold, silver, copper and zinc prospects and mines. The carbonate mine is the most extensively developed property in the district. It produces lead-silver ore, associated with limonite and manganese. A shoot of rich gold rock was discovered in the mine some years ago and subsequently lost. This shoot was from an inch or two to nearly a foot in thickness and consisted almost wholly of calcite, with occasional stains of iron and manganese, with a little quartz. Gold could be seen in the greater part of it.

A mile and a half east of Oro Grande are several copper prospects on which considerable development has been done in a superficial way. Half a mile to the northward from the copper mines, lead and zinc ores with silver are found. Nearer Oro Grande station is a large deposit of ferruginous quartzite, which may contain gold, but which has never been prospected. Geologically, this quartzite is identical with that at Gold Mountain, 40 miles east of this place. The latter is known to be gold-bearing and is owned and operated by J. R. DeLamar.

Oro Grande, Feb. 23.

The Copper Chief mine, 8 miles from Victor, is having machinery installed by the new owners.

SAN DIEGO COUNTY.

At the Picacho mines, owned by the California King G. M. Co. of Picacho, 30 miles north of Yuma, 300 tons of ore are being handled daily, but this spring their milling capacity will be doubled. An open cut, 53 feet deep, across a ledge is the present ore supply. The ledge is 160 feet wide, all of which is sent to the mill. Its assays average \$4 in gold, and the ore can be quarried for 10 cents per ton, says Superintendent E. Gee. It can be taken out, crushed and leached for less than \$1 per ton. It is crushed to twenty mesh and cyanided, by which 90% of the values are saved. In addition to the vein now being cut through, two others are being exploited, one of average value of \$5 per ton, the other 20 feet wide and \$6 per ton. On this latter vein a shaft is down 200 feet. They have 120 men at work.

The High Peak and Washington mines, near Julian, have a few miners at work on free milling ore. Some rich ore was recently taken from the Washington mine, twenty ounces of which gave \$3.60.

O. Welburn, who has a bond on the Ranchita mine, near Banner, is clearing out the shaft and levels to make an examination. This mine has produced some rich ore, but has not been worked steadily for several years.

It is reported that the Free Coinage group of mines, near the Noble property at Pine Valley, have been bought by Marr & Middagh of Colorado Springs, Colo. The veins in this district are usually small, but carry high values. They are fissure veins and lens-like sheets in micascist.

SANTA BARBARA COUNTY.

A rotary jig has been installed on the property of the Western Union Oil Co. at Careaga.

The Union Oil Co. of Lompoc has struck oil in its well on the Purisima ranch at a depth of 2000 feet and the oil is within 100 feet of the top of the pipe. They have decided to continue drilling, as the shale formation continues.

SHASTA COUNTY.

The Sam Houston M. Co., will resume operations on the Sam Houston mine in Old Diggings district, near Redding. F. P. Poor of San Francisco is superintendent and part owner.

The ledge of the Lone Jack mine of the Enterprise group, near Redding, is showing 9 feet wide and averages \$10 per ton. The lower tunnel, in 1200 feet, is in the pay chute, which was abandoned in the upper workings two years ago on account of water and lack of pumping facilities. In the Enterprise mine of this group Day Bros. are driving a tunnel in the lower workings. It is expected the mill will be in operation by March 1st.

J. E. Lewis of the executive board of the Western Federation of Miners returned to Keswick last week, and at a meeting of Keswick union a motion to renew the strike was defeated by a vote of 55 to 41. One furnace at the Keswick smelter was in operation, and Manager Wright says he can keep it running without union men, and when desired will blow in more furnaces. There are 150 men in and about the smelter who did not walk out when the recent strike was called.

H. G. Scrivener, with W. T. Wickes and O. B. Sherman, owning the Pawnee group of claims on Wild Cat, 3 miles from Bear Valley station, near Redding, reports an 18-foot ledge of \$20 ore opened.

W. W. Adams, superintendent of the Balaklala mine, has contracted for material and supplies for the new offices to

replace the building destroyed by fire some weeks since.

Judgment has been rendered in favor of A. J. Cook in an action involving the possession of the Enright smelting plant on North Cow creek, near Furnaceville.

SISKIYOU COUNTY.

H. Grayson, who bought the Punch Creek quartz mine on Humbug, near Yreka, is rigging up a water wheel for power to run pumping machinery. A 10-stamp mill is to be erected, and will be operated by power from the Siskiyou Electric Power Co., now extending wires from their plant at Fall Creek, Klamath river.

Work is in progress at the Spengler Bros. placer claim at mouth of Humbug. They are building a new reservoir and replacing new sluice boxes washed out during the heavy rain storms.

S. Gardner of Scott Valley has bought a three-eighths interest in the Eastlick Bros' hydraulic mine at Oro Fino. The claim is being worked. There is abundance of water for operating the giants and elevators until late in the summer.

Manager G. Rymal of Yreka reports having struck a ledge of pay quartz at Anderson Ferry on north side of Klamath river, owned by W. H. Jones of Chicago, Ill. The ledge is 4 feet wide; several tunnels have been driven and a mill will be erected.

The Jillson quartz mine, near Hornbrook, will resume, says Superintendent C. B. Jillson.

A. J. Ball of Rollins, operating on Methodist creek, southwest of Sawyer's Bar, is driving tunnels on his mine and in the spring will put in machinery to work the ore already blocked out.

F. W. Mahler, superintendent of the Deadwood hydraulic mine, near Yreka, has resumed operations, as there is an abundance of water, and with the snow from 4 to 6 feet deep Mahler says the mine is assured of water to keep running until next fall.

SONOMA COUNTY.

J. L. Cramer of Petaluma reports having opened up a 12-foot ledge of gold ore, assaying \$12, in the Cramer mine, near Glen Ellen.

TRINITY COUNTY.

Superintendent G. Lowden of the Three Peaks quartz mine on Battle creek, in Coffee Creek district, near Carville, says he is building a mill on the property, and the ledge being developed has widened to 8 feet.

F. and G. Lowden of Lowden's Ranch are developing a quartz ledge which they located on Saw Mill gulch, near Grass Valley creek. They have a 3-foot ledge of good ore.

The La Grange Co. contemplates building a large reservoir on the divide above the mine. It is reported that the large pipe which was laid by the Sweepstake Co. has been bought and will be tapped in a suitable place and used to pipe out the site of the reservoir. For 1 mile back the bank is cracked, necessitating the removal of the present reservoir. The construction of a new reservoir will admit of working the entire west side of the mountain.

The Lappin mine, near Deadwood, has been bonded by its owners to J. J. Chambers & Co., of Redding, Cal., for \$100,000.

The Homestake group, owned by Reed & Given, near Trinity Center, have shut down for the winter. This group lies half a mile up the mountain opposite the Enterprise mill. A tunnel has been run on the vein 150 feet, between walls of porphyry and slate. The vein runs from 8 inches to 5 feet in width, and carries free gold and sulphurets. A 60-foot shaft has been sunk on the vein.

At the Evans Bar claim, near Douglas City, three giants are being operated. C. Carr has a lease on the mine, which has an 18-foot bank of gravel.

TUOLUMNE COUNTY.

Fifty men are at work at the Republican mine, Jacksonville, and twenty stamps are dropping in the mill.

At the Mobian mine, near Groveland, Superintendent F. Chappellet is cutting a station at 500 feet in, in Tunnel No. 1, for an underground hoist, to have a capacity of 2000 feet. This hoist will be run by compressed air. Tunnel No. 1 is on the mill level.

The shaft at the Campo Seco mine, near Jamestown, is down 130 feet. Of this the first 60 feet was a two-compartment shaft, below which point the shaft was enlarged to three compartments. It will be made three compartments throughout by raising from 60 feet to the surface. Superintendent Hall says a large steam hoisting plant will be put in soon, and the gasoline hoist now in use at this mine will be removed to the company's mine at Nigger hill, half a mile southwest of Jamestown, where Superintendent Pinney is sinking a shaft for prospecting the vein.

S. Ball and W. Divoll, working the Hahapoo mine, north of Columbia, report

having struck a pocket last week, valued at \$7000.

A. T. Barlow of Columbia has bought a one-quarter interest in the Oklahoma and Arizona quartz mines, on the south fork of the Stanislaus. F. B. Price has bought the Salamander quartz mine, near Columbia. The McAlpine G. M. Co. has bought the Big Joe and Little Ben quartz mines. The Mountain King M. Co. have bought the Victoria Extension and Mountain King mines, near Confidence.

COLORADO.

BOULDER COUNTY.

The Valley Forge mine at Boulder, owned by Colorado Springs men, last week sent out a shipment containing three grades of ore which returned first grade, 31.20 ounces gold per ton; the second grade, 9.20 ounces per ton, and the third, 3.01 ounces. The vein is 7 feet wide and the ore shoot has been proved up for 90 feet.

The United States G. M. Co. has incorporated to operate a group of mines below the Fourth of July mine, near Eldora. A tunnel is being driven to open up the ledge at 1700 feet and a depth of 1000 feet. A complete plant of machinery will be put up in the spring. J. F. Rowell, of Eldora, is manager.

CLEAR CREEK COUNTY.

The 160 H. P. boiler and compressor on the Terrible mine of the Elkins M. & M. Co., near Silver Plume, are in operation and the shaft is being unwatered, which is expected to reach the 15th level by April 1st. The main shaft will be retimbered. Operations on the mill are being rushed.

The Hazleton M. Co. will begin operations on the Baltimore and other lodes, near Silver Plume, and the plans include the erection of a plant of machinery for driving the tunnel sinking the shaft and exploring ground, and the construction of a concentrating mill.

In the Penzance, near Freeland, in excavating for the compressor power house, another vein was cut at the surface, showing 5 feet of ore running \$4 per ton. The shaft is on the south side of the gulch, where a hoisting plant has been placed. At 100 feet a crosscut was started and is 45 feet to the west. Another 65 feet is expected to bring it to the new vein. Manager T. S. O'Neil has bought the Allan mill and will have it in operation by March 15.

The Freeland Con. M. Co., of Idaho Springs, has bought the Turner, Anchor and Falu mines near Freeland, and on the line of the Monarch tunnel. G. McClelland is manager.

The plant of machinery at the Terrible mine, near Georgetown, is in operation. The workings are being unwatered and by the time they are ready to break ore the mill will be completed.

The Nevada Con. G. M. & M. Co. made a shipment of 100 tons to the Rocky Mountain concentrator at Black Hawk last week. Development work is carried on at the Lamberson and Warren mines of the company's group on Kling flats, west of Nevadaville.

Arrangements are being made by Denver men to lease the Pay Rock mill, near Silver Plume, which will be used for concentrating ore from the upper Mendota dumps, and other zinciferous ores. The machinery will be overhauled. J. Thomas will have charge of the mill.

The Santiago, in East Argentine district, has struck ore which assays 20½ ounces of gold per ton and 2270 ounces of silver. The shipments from the mine have shown gold values for some time.

Haggart & Co. took a lease in 1900 to drive the 1000-foot level west to cut the ore body of the Aliunde mine at greater depth. In June ore was found on that level, and since shipments have been regularly made, the ore being high grade. This lease alone has produced \$90,000, with considerable ground yet to be worked out. In January the output was \$7000, and last week a shipment of 40 tons yielded \$8000, the first class running 740 ounces silver and 50% lead per ton, and the second class 286 ounces silver and 10% lead.

J. Cousins, working the Crazy Girl mine, at Freeland, reports having opened 12 inches of smelting ore in the adit level. With it is a streak of milling ore. It is the intention to continue drifting on the ore body and sink the shaft on the shoot.

DOLORES COUNTY.

E. Flene of Dunton says he will resume work on his mines in Navajo basin this spring, and will build a mill in the basin this summer.

EAGLE COUNTY.

The lessees on the Mary Cashen, on Battle mountain, are shipping smelting ore from the 350-foot level, where they made a strike a few months ago. The vein is very irregular. The leasing company has paid to the company in royalties \$1400.

EL PASO COUNTY.

President Fullerton, of the Telluride mill in Colorado City, met a committee from the Mill and Smeltermen's union the 19th inst., at his request, and informed them that he would recognize the union and that he was in no way opposed to organized labor. Men who have been receiving \$1.80 at his mill will be raised to \$2. This will be temporary, until a permanent scale is adopted for all three mills.

FREMONT COUNTY.

The United Oil Co., near Florence, drilled into oil in well No. 307 on the 20th inst., being the third well for the week.

A. N. Moore, manager of the Portland Cement Co., near Florence, has located a deposit of gypsum less than a mile from the plant on the other side of the river. About 2% of gypsum is used in the manufacture of the Portland cement.

The Empire Zinc Co. are putting in four more electrical separators at their Canon City plant, making a total of six, which will give them a capacity of 100 tons per day. In addition to this they have a capacity of 100 tons daily of mechanical table separation. This increased capacity is to handle the increased output in Leadville, all zinc ore handled at this Canon City plant being from Leadville.

The Stadacona Oil Co. reports having struck oil in its well between Florence and Coal creek. Pumps will be put in.

GILPIN COUNTY.

Denver parties will reopen the Star of the West mine, in Lake district, near Central City, under a lease and bond. There is a shaft down 330 feet.

The Cleveland M. Co. is working two shifts at its Spur Daisy shaft, in Eureka district, near Central City. The shaft has been retimbered and sinking resumed from the 300-foot level. When the 600-foot mark is reached the company will install a larger plant of machinery. They are operating the Bon Ton claim in the same group and sinking the shaft to 300 feet. J. Brohl is superintendent.

During the past month the ore shipments from the Quartz hill mines of the Kansas-Burroughs Con. M. Co., near Central City, were 180 cords, of which 165 cars were handled by the Gilpin Tramway Co., the balance being hauled by wagon. The principal part of this production was sent to the stamp mills and concentrator, some ores going to the smelter. They have seventy-five men at work.

The Storm King mine, owned by the Argo G. M. Co., at a depth of 45 feet, is in free milling gold ore that runs \$16 per ton. The vein is 4 feet wide. The company also owns the Denver group of four claims on Independence hill, in Leslie gulch, 2 miles southwest of Rollinsville and 1 mile from the line of the new Moffat road. With the erection of a custom mill at Rollinsville they expect to develop their claims into a paying mine.

The Carcasone M. Co., near Central City, have begun sinking a new shaft on the -traughton lode, one of the cross veins on its property in Illinois Central district, and operations are temporarily suspended on the Detrich claim.

Curnow & Co. have started operations at the Ute mine on Quartz hill, near Central City, and are at work in the 400-foot level, where they have a shoot of smelting and milling ores.

The Aurora mine, near Russell Gulch, has been leased and bonded to Cripple Creek parties who will operate it as the Cripple Creek Gold Temple M. Co. The main shaft is down 400 feet, and will be unwatered, the machinery overhauled, and development work begun.

GUNNISON COUNTY.

A strike is reported made last week on the Gold Hill mine in Taylor Park, near Placer, and northwest of Tincup, showing 2 feet of ore assaying \$300 in silver, gold and copper.

Development work is being done on the Big Medicine and Rough Rider groups. The Big Medicine shows 30 inches of free milling ore, running \$15, and the Rough Rider on Red mountain has a 70-foot tunnel, with 4 feet of free-milling ore, running \$20. A mill will be built this spring. The properties are owned by B. W. Snedeker, A. O. Prose and W. B. Wheeler.

The Tilden Co. has opened a 20-inch shoot of lead carbonates in the incline shaft of the Red Cloud, on Tilden mountain, near Tin Cup.

The Gold Cup mine is being operated from the ninth to the eighth level. In the eighth level a winze is showing a body of ore that carries values in silver.

LAKE COUNTY.

H. C. Burrell, operating the Hopkins property on Mount Sheridan, is taking out considerable lead ore.

The Morocco shaft of the Home Extension M. Co. has found a market for sixty carloads of manganese ore monthly at the Pueblo steel works. The manganese is

worth net \$3 50 a ton. The Morocco shaft is worked under management of A. M. Gaines, receiver.

The new mill of the Resurrection Co., back of Broeze Hill, has a capacity of 150 tons of ore daily.

Mines in the Tin Cup and Taylor Park districts are showing values in lead and zinc, and the prospects for increased output from this section are good.

The Forest Hill Con. M. Co. has a group of thirty patented claims, near Pitkin. They are sinking in a 375-foot shaft, from which levels are run every 75 feet. The vein has been cut by four levels run and the fifth is in 375 feet. The ore is zinc and lead sulphide in walls of granite. The concentrates run \$70 to \$75 per ton, concentrates 10 to 1. The plant has a capacity of fifty tons per day. The mill is to be enlarged.

Manager Evans of the Home M. Co. at Leadville says he will increase the output to 300 tons per day. The grade of the iron being low, the net profit is about 50 cents per ton.

Manager Brenneman of the Rex mine at Leadville, says the Rex shaft has been unwatered. The pumps are throwing about 1000 gallons of water per minute.

Manager T. Owens of the La Belle M. Co. is shipping siliceous ore from the Black Prince shaft, near Leadville.

Manager Dwyer of the Empire Zinc Co. says because of the increased output of their mines at Leadville they are increasing the capacity of their concentrating plant at Canon City.

The Big Evans Gulch M. Co. will put in two large boilers to replace those at shaft No. 2, on account of the increased flow of water met with in sinking the shaft. Manager Collins says he will start the Hoffer shaft on the same property next month.

LAS ANIMAS COUNTY.

Two hundred and fifty feet of the workings of the Engleville coal mine have been cleared and fifty men are at work. The debris which accumulated during the recent fire is being hauled from the mine by hand, the track in the mine having been destroyed by the heat. The fire is still burning in some parts of the mine. There are 1200 feet of workings yet to be cleared and the entire area burned will be retimbered. It is expected the mine will be in full operation by April 1.

LARIMER COUNTY.

A strike of copper ore is reported on the Bonbright mine, in State Line camp, 4 miles north of Pearl. The vein cut in the shaft shows 2 feet of mineral, which assays 20% copper. There is also a body of milling grade. The high grade is being sacked and shipped.

OURAY COUNTY.

The Bachelor mine, near Ouray, is working 100 men on the Khedive tunnel and the mill is treating twenty-five cars monthly.

PARK COUNTY.

In the South London mine, near Alma, a vein of ore 4 feet wide, averaging \$100 in gold is reported, struck in the tunnel, being driven with machine drills. The ore was found 300 feet from the surface. E. W. Logan of Denver is manager.

A vein of ore 4 feet wide and averaging \$100 gold a ton has been struck in the South London mine, near Alma, says J. H. Kuhn, superintendent.

SAGUACHE COUNTY.

A strike of 12 feet of milling ore is reported from Crestone in the lower tunnel of the Cripple Creek-Idaho M. Co. property, on Short creek. The Star Isabel Co., north of Crestone, has men at work overhauling their mill preparatory to starting up next week.

SAN JUAN COUNTY.

The Orado G. M. Co. has been incorporated to operate, near Eureka, the Carle G. and Hydrant groups. The Hydrant millsite is included in their holdings. The main shaft is down 700 feet. The smelting ores average \$40 per ton, and the milling ores \$6 per ton. The plant of machinery will be increased.

Contracts are to be let for a 100-stamp mill for the Gold King Con. M. Co. of Silverton, says Superintendent W. Z. Kinney. The company already has an 80-stamp mill in operation.

SUMMIT COUNTY.

The Iron Mask, near Kokomo, will be reopened by the Arkansas Valley Smelting Co. The Iron Mask is said to show bodies of sulphide iron.

TELLER COUNTY.

The English-American G. M. Co., sub-leased on block 7 of the school section at Cripple Creek, are drifting for the ore shoot that was opened in the 90-foot level.

The estate of the Sacramento G. M. Co. on Bull hill, Cripple Creek, is to be worked again. The west end has been

leased to J. H. Hunt and C. D. Taylor. They will use an incline shaft which was sunk to 200 feet. It is provided in the lease that should they do any sinking it must be started from the surface and be 4 by 8 feet. The east end has also been leased. That part is developed by an incline shaft down 180 feet. The group owned by the company consists of the Sacramento and the Midnight claims, a total of seven and a half acres on Bull hill, near the Last Dollar and the Specimen.

The Amethyst G. M. Co. has given a lease on the Alexander Marsh claim on Raven bill, Cripple Creek, to McMullen & Co. The shaft is down 115 feet, and will be sunk 200 feet deeper. A new plant of machinery will be installed.

The August Flower Leasing Co., operating the Katinka group of claims, on Guyot hill, Cripple Creek, will put in a plant of machinery at their three-compartment shaft, including boilers, a seven-drill compressor, and a hoist with capacity of 1000 feet.

The Vindicator Co. is handling 500,000 gallons of water per twenty-four hours, of which 400,000 gallons are being furnished the city of Victor for domestic purposes. No attempt is being made toward a production from the 1100 and 1200-foot levels. The regular production of 1500 tons of ore a month is being maintained.

Asbestos is reported in the bottom level of the Modoc mine, on Battle mountain, near Cripple Creek.

The three-compartment shaft of the Golden Cycle Co., Cripple Creek, is down 1000 feet, and an additional 200 feet will be sunk before spring. Kenron et al., operating the Ida C., are putting in an air compressor.

Lessee J. K. Lewis, operating on the J. I. C. and Sweepstakes claims of the Republic Co., near Cripple Creek, has opened up a 3 foot vein, which averages \$12 per ton. The Fulton-Marguerite M. Co. has granted a two years' bond and lease on its Marguerite claim on Gold Hill, near Cripple Creek, to L. S. Boswell, for \$15,000.

The total production from the various workings of the Elkton Co., Cripple Creek, averages 900 tons of ore per week, says the Times. Of that amount the company is shipping 400 tons that will average \$20. The best showing in the company's workings is in the seventh level, south. A raise being made from that level shows the ore body 3 feet wide. The main seventh level is being driven north of the shaft and drifting is in progress on the Walter vein. There are ten sets of lessees operating on the group, all shipping. Lessees McFee & Ebe, on the Raven vein, being worked from the Raven tunnel, on the Anaconda side, are taking out ore from a 4-foot body that averages \$20 per ton in gold. They are shipping one car per week.

At the Bolivia mine, near Gillett, the shaft house, which was burned down a short time ago, will be rebuilt and machinery installed. The shaft is 400 feet deep and will be sunk deeper. Manager J. Parfet of the Streeter & C. C. Co., at Gillett, says a plant of machinery will be installed on the Snowshoe claim. At a depth of 100 feet a vein was cut which assays \$15.

Popst, Connor & Williams, leasing on the Acacia, at Cripple Creek, say they have proven up the ore body sufficiently to begin figuring on installing machinery.

Ball & Franklin have a two years' lease on the middle block of the Forepaugh Co. ground, on Squaw mountain, near Cripple Creek, with a 20% flat royalty.

The shaft on the Bolivia mine, near Gillett, will be sunk from the 400-foot level to the 1000-foot. A company has been organized to prospect the group, and the Rustic and Necessity claims have been consolidated with them, making a total of fifty acres. The shafthouse will be rebuilt and machinery capable of sinking 1000 feet will be installed.

Eastman & Co., having a lease in the lower tunnel of the Sunset-Eclipse mine, Cripple Creek, have opened up an ore body that is being broken 4 feet in width and averages \$20 per ton without sorting. They expect to get out a carload per day. The Cripple Creek Good Will Temple M. Co., operating the Gold Sovereign claim, on Bull hill, Cripple Creek, will resume sinking next week and make their shaft 150 feet deeper (700 feet total). Their lease has been renewed.

This week the El Paso Co. started the fifth heading in the drainage tunnel, from the north side of the main shaft at a depth of 600 feet. This lateral will be 1000 feet long before reaching the dyke that carries the main water course of the west side of the camp.

The Gold Coin Co. is employing 130 men, producing eighty tons of ore per day, which averages \$35 per ton.

IDAHO.

BLAINE COUNTY.

On the 18th inst. a fire at the Minnie Moore mine, near Bellevue, destroyed the

pumphouse, carpenter shop, changeroom and storehouse and damaged the mine. Thirty-six men were employed at the mine. The loss is \$6000.

BOISE COUNTY.

At the Overlook group of mines, near Boise, the Chilian mill will be in operation by April 1st, says Superintendent E. Johnson.

The Mineral Hill group of quartz claims, near Placerville, has been bonded for one year to J. O. Barber for \$20,000.

CURRY COUNTY.

The Golden Eagle Dredging Co. of San Francisco are preparing to work a group of 940 acres of placer ground 9 miles from Port Oxford, and extending several miles up Sixes river.

CUSTER COUNTY.

The Lion Creek G. M. Co. has incorporated to operate a group adjoining the Last Packer mine, on Loon creek, with R. McBeth of Custer, C. K. McCornick, D. H. Peery et al. of Butte, Mont.

IDAHO COUNTY.

In the Big creek section, near Tbounder, the Crown and Golden Gate groups of twenty claims are being developed. A crosscut will be driven on the Golden Gate to open up the ledge at a depth of 200 feet. The ore assays \$5. In the spring it is intended to install an electric power plant on Johnson creek, capable of generating 200-horse power, and a cyanide plant on Smith creek, says Manager D. Mackenzie of New York City. On the Crown a contract has been let for 300 feet of tunnel work, to be completed by May 1, which will open the ledge at a depth of 250 feet. Operations are resumed at the Dewey mine and mill, near Thunder.

LANE COUNTY.

The Lucky Boy mine, near Blue Pines, has closed down for the winter on account of snow being too deep in the timber to get out material for the tunnel timbering. About thirty men have been at work.

OWYHEE COUNTY.

Manager McKean, of the Alta-Vista M. Co., near Silver City, reports opening up an ore shoot, near the Black Jack mill, which runs \$400 per ton. Arrangements are being made to operate the drills by electricity.

SHOSHONE COUNTY.

The Basin M. Co., owning a group of claims adjoining the Hercules mine, near Wallace, are driving their crosscut tunnel. The snow is 15 feet deep.

Manager W. L. James of the Alameda silver-lead mine up Nine Mile canyon, near Wallace, says they have their crosscut tunnel in 400 feet and last week a vein 2½ feet wide containing galena was found.

The New Jersey G. M. Co., which has bought the group of claims 3 miles east of Wardner, on Gold Run creek, will put up a 10-stamp mill.

There is a local report at Wallace that there is an effort being made to consolidate all the silver-lead mines of the Coeur d'Alenes under one company. It is said the American S. & R. Co. has agreed to take sufficient stock to have the controlling interest. The only properties not in the deal are the Hercules and the Empire State-Idaho Co.

O. P. Lee, a miner, was crushed to death at the Bunker Hill & Sullivan mine last week by a cave in the roof of the drift. He was engaged with another man timbering the drift at the time.

Because the mine was not being worked at a sufficient profit sixty-seven men were laid off permanently at the Frisco mine this week. The day shift of the mill has been closed and from now on will run only during nights. A force of 175 men is retained, but previous to this lay-off another force had been released. The cause for the reduction reported by the management is that the ore in the upper workings is too low grade to be mined at a profit. The men who have been retained will work on the 2000 level. About the last of March the shaft will be sunk to the 2100-foot level.

A shoot of galena was struck last week in the Constitution mine, owned by F. Gilbert & Co., on Pine creek, near Wardner, on the foot wall at 190 feet from the mouth of the tunnel. There is zinc ore on the hanging wall.

MICHIGAN.

HOUGHTON COUNTY.

The management of the Allouez mine, near Calumet, has decided to sink a vertical shaft to strike the Kearsarge lode, which is thought to underlie the property at a depth of 1000 feet.

At the Quincy mine, near Hancock, thirty jigs will be put in, completing the equipment of the new mill, making ninety-two in all. The company finds with the new mill and mill equipment a saving of 6 cents per ton in the cost of handling rock,

being reduced to 20 cents per ton. The Quincy is handling coal from the dock to the mine for 10 cents per ton, as compared with an average cost of 50 cents at the other mines.

The Champion M. Co., near Houghton, is clearing land for the erection of twenty-five additional houses near the thirty just completed. The Trilmountain will build fifty houses in the spring.

From all the openings on the branch vein at the Michigan, near Houghton, last year an average of 480 pounds of mass and barrel copper were sent to the smelter for every cubic fathom of ground broken. The crosscut to the branch vein from the 12th level of B shaft is in 150 feet. B shaft is sinking to the 13th level. Fourteen drills are working in the mine. The branch is said to be making towards the Minnesota conglomerate.

The Copper Range Railroad is hauling five carloads of refined copper from the smelters daily, this representing the output of the South Range mines. The new machine and blacksmith shop of the Champion is now ready for equipment. No. 4 shaft of the Trilmountain will be producing by July.

ONTONAGON COUNTY.

The result of last year's operations at the Mass mine, near Ontonagon, shows an output of 2,700,000 pounds of refined copper, which was marketed at an average of 12½ cents per pound.

G. L. Walker of Boston says negotiations are on for the consolidation of the Adventure, Mass, Michigan and Victoria mines, near Ontonagon, and to also purchase several inactive properties in the same district and operate them together, the Victoria water power to generate electric power for the development, mining, milling and local transportation purposes.

ST. CLAIR COUNTY.

At the Capac marsh, 3 miles from Capac, the American Peat Fuel Co. of Calumet are taking out peat, and they have installed briquetting machinery. By spring they expect to be producing 200 tons a day, for which they are getting \$4 per ton. The peat covers an area of 2200 acres and lies to an average depth of 16 feet. Six hundred tons of raw peat are required to produce 200 tons of briquettes.

MONTANA.

BEAVERHEAD COUNTY.

P. M. Sweeney has located a graphite claim in the Sheep creek basin, near Dillon. The vein is 30 feet wide. Samples sent to the Dixon Graphite Co., Jersey City, N. J., are reported to be of good quality.

Copper glance assaying 25% has been found in the Monument mine, Bloody Dick district. The ore will be shipped. Hundreds of tons of copper ore are reported exposed on the surface. The ore also carries gold values.

DEER LODGE COUNTY.

The Homestake M. Co. has bought the Sailors Dream mine for \$25,000. It is a gold proposition and contains some rich ore.

FERGUS COUNTY.

Manager W. M. McLean of Lewistown says a mill will be erected in the Little Rockie by the Alder Gulch M. Co., of which E. W. King is president. The company's group includes nine patented claims, and it is a cyanide proposition. The mill will be of 100 tons capacity. Ad Mont.

LEWIS AND CLARKE COUNTY.

C. Hartman and T. Cooney of Helena have a bond on all of the Opbir placer claims below Helena, comprising a strip of 2 miles long and ½ a mile wide.

MADISON COUNTY.

Two new 100 H. P. boilers are being put in at the Galena mine, near Sterling.

MISSOULA COUNTY.

G. H. Loehr and P. M. Mahler of Chicago have control of the Amador copper mine, near Iron Mountain. All details have been completed and operations will be resumed.

VALLEY COUNTY.

Oil seepages have been found south of Malta. A company will make a test of the field by drilling.

NEVADA.

ELKO COUNTY.

At the Wakefield mine, near Tuscarora, operations have been suspended, owing to failure of pump to handle the water.

EUREKA COUNTY.

W. H. Tibbals of Salt Lake City, Utah, has bonded a group of fourteen claims in the Diamond district for \$60,000; time, eighteen months.

ESMERALDA COUNTY.

The Southern Nevada G. M. Co. has bought a group of mines near Red Mountain and Silver Peak. Development work will be continued and a reduction plant built at Silver Peak.

LINCOLN COUNTY.

The Cyrus Noble M. Co. has incorporated to operate the Otis mine near Searchlight; G. E. and K. M. C. Otis, H. Surr, A. S. Auchinloss and S. A. Marsh. The principal place of business is Redlands, Cal.

The shaft at the Techaticup, at El Dorado canyon, will be sunk to an additional depth of 420 feet.

Smith & Bowman have temporarily suspended operations on their Summit Springs group, near Searchlight.

The new mill of the Quartette Co., at Searchlight, will have cement mortar blocks and other modern equipment. The water supply is obtained from the Colorado river.

NYE COUNTY.

In the Montana-Tonopah shaft at the 600-foot level, ore stringers and decomposed quartz extend nearly across the bottom of the shaft. This is 50 feet below the drifts on the ledge from which the ore is being mined.

T. Colehan, vice-president of the Coleman M. Co., near Butler, says the shaft on the Eliza Jane claim is being sunk to 200 feet, and another shaft will be sunk on the Polo claim.

The Florence Extension M. Co. has incorporated to work a group of seven claims in Liberty district, 25 miles north of Butler; T. Fleming, W. Tamblin, R. Dougherty and F. H. Maxwell.

A new mining district is reported by the Tonopah Bonanza, 25 miles southwest of Butler. There are seven ledges in granite, slate and limestone. The veins are described as large and containing \$5 and over per ton gold. Thirty claims have been recorded in the new field, which is known as the Grandpa district. There is a spring flowing 3 inches of water within 1/2 mile of the first locations made.

STOREY COUNTY.

Operations at the Con. Virginia are continued with no important change. The water at the Combination shaft stands at 200 feet below the floor of the 1950 station, or about 400 feet below the Sutro tunnel level.

There is a strike at the Butters cyanide plant in Six-mile canyon, near Virginia City, owing to the men being paid at the rate of 30 cents per hour instead of \$3 per eight-hour shift.

Superintendent E. M. Gorbam has resumed work on the Brunswick lode, near Virginia City. The steam hoist will be used until electric motors and machinery are installed.

WHITE PINE COUNTY.

A strike is reported on the 300-foot level of the Saxton mine at Ely of black copper sulphide ore which assays 4 1/2% copper and \$5 in gold.

NEW MEXICO.

GRANT COUNTY.

The Comanche M. & M. Co. has bought the Silver City smelter. The plant has a capacity for treating 250 tons per month. The Silver Cell silver mine at Pinos Altos has been reopened by Dimmick Bros.

F. Deming says a flow of water has been struck in the Neosho shaft, owned by the Alessandro M. Co., near Silver City. The flow averages 10,000 gallons a day and the shaft will be sunk deeper. A 50-ton leacher will be installed.

The Lena concentrator at Lordsburg has been sold to the American Con. Copper Co. Machinery will be added.

The present production from the iron mines of Fierro and Hanover is 1000 tons daily, averaging 56%. Part is shipped to Pueblo by the Colorado F. & I. Co., and the rest to El Paso for smelter flux.

OREGON.

BAKER COUNTY.

Superintendent H. D. Spaulding of the Del Monte mine at Sparta says that on the 180-foot level they have crosscut a 14-foot ledge of sulphide ore.

The Gem mine, near Sparta, owned by A. Geiser of Baker City, is sinking to the 600-foot level, opening up ore.

It is reported that at the I. X. L. mine, near Baker City, last week while driving a crosscut in the lower workings in opening a vein of ore they tapped a stream of water which forced the men out of the mine. The machinery was inadequate to handle the flow. The mine was closed down temporarily, as the snow is too deep to bring in additional machinery. F. Kelly is manager.

Miners at work in the White Swan

mine, in the Virtue district near Baker City, struck the "red" ledge last week in a crosscut from the third level.

The Badger Co. is sinking on the Bull of the Woods claim of the Homestake group, near Sumpter. At present the concentrating plant is not operating, freezing having injured some of the water pipes. Driving the adit tunnel to connect the shaft with the mill continues from both directions.

Manager C. R. Aldrin, of the Tempest mine in Greenhorn district, near Sumpter, says a matte smelter will be installed this spring.

Another strike has been made in the Old Virtue mine, 6 miles east of Baker City, says Manager Buckbee. The ore was found in a pocket. One piece weighing ninety-two pounds yielded \$10,000.

JACKSON COUNTY.

The Opp quartz mine (the Beckman & Huffer mine), near Jacksonville, has been sold for \$150,000 to a Boston company. A. U. Mills of Tacoma, Wash., is president. A 20-stamp mill will be built. There are 2000 feet of tunnel and shaft work done.

D. S. Sanford of the Shorty Hope M. & M. Co. says work will be resumed on the Shorty Hope quartz mine, near Ashland.

JOSEPHINE COUNTY.

The Scribner-Henderson mine, near Wolf creek, has been sold to the Mountainview Copper Co., of which W. E. Olmstead is manager, and which owns copper interests in the Waldo district. The Scribner-Henderson ores are free milling and development will begin next week and a complete plant and mill will be installed.

SOUTH DAKOTA.

CUSTER COUNTY.

Manager D. Henault of the Crown mica mine, near Custer, has resumed work on that property.

The Extreme M. & M. Co. of Custer owns three groups of mines near Custer. On the London group, one of these, a plant of machinery is to be built. The ore will be treated by cyanide or by the chlorination process. I. Downing of Custer is superintendent.

The shaft of the Gertie Co., near Hill City, is down 500 feet. The vein contains both gold and cassiterite; E. C. Johnson, superintendent. A crosscut is being run to reach the vein, which in sinking dipped out of the shaft.

LAWRENCE COUNTY.

The Golden Reward Co., at Deadwood, have their large cyanide plant in operation, although the smelter is shut down by reason of the strike. It is reported the management is considering the advisability of shipping the high-grade ore to Omaha for treatment.

J. R. Pbelan is preparing to ship ore from the Blon mine, near Galena, to the Rapid City reduction works.

A mill test has been made on ore from the claims of the Ak-Sar-Ben G. M. Co., on Annie creek, near Terry, and gave returns of \$10.40 a ton, the extraction being 71% by crushing to 30-mesh. The ore had been taken from three openings on the company's property and was a general sample of the ore exposed. A similar test was made on ore from the main shoot of the University Co., adjoining the Ak-Sar-Ben group. The mill extraction was 73% at 30-mesh. It is a shale ore, similar to that found in the Dakota in the vicinity. The Dakota Co. is making a profit of \$1.18 a ton on \$4.11 ore. The ore is hauled 8 miles by railroad to the Deadwood mill of the company. The Ak-Sar-Ben and University companies have had a millwright and engineer on the ground and a preliminary survey has been made for a mill to be built jointly.

The University G. M. Co., on Annie Creek, near Terry, has developed an ore body reported 50 feet wide, 18 feet thick at the center and of unknown length. The ore averages \$6 per ton. This is one of the flat sheets occurring in the Cambrian. A mill will be built in the spring. R. Fitzgerald of Deadwood, superintendent.

The Gladiator M. Co., of Deadwood, will build a 100-ton cyanide mill in Deadwood gulch, a mile above Central City. C. H. Crabtree, of Des Moines, Iowa, general manager, is in charge.

UTAH.

BEAVER COUNTY.

H. M. Crowther, managing director of the Blue Acre Copper Co. at Blue Acre, says shaft No. 1, down 100 feet, has struck an ore shoot along the foot wall of the vein which assays 11.6% copper, 7.2 ounces silver and \$6 gold. The shaft will be continued to the 200-foot level, from which point drifting and crosscutting will begin. L. E. Kiser is superintendent.

Superintendent G. Morehouse of the Erie M. Co. mines adjoining the Majestic,

near Milford, says at a depth of 175 feet the shaft has cut 8 feet of copper-bearing quartz.

At the Beacon mine, near Shauntie, out from Milford, last week, the tunnel being driven for the old workings cut the vein, opening up a body of carbonate ore, carrying 45% iron, with values in gold and silver, a flux sought by the smelters. The tunnel will be pushed ahead to the incline 20 feet farther, giving it a depth of 80 feet. The Beacon is owned by A. Potberingham, J. Forgie, J. Leysbon, G. Reynolds and C. Smith.

G. Moore, manager of the Atlas mine, near Milford, says he has men at work developing a body of milling ore that will justify installing a concentrator. The ore body is 20 feet wide and carries 12% lead.

The shaft at the Beaver Con., near Milford, is 160 feet and will be sunk to 500 feet before crosscutting for the vein is begun. Twenty-seven men are employed at the Beaver Con. and Ben Harrison.

At the Old Hickory mine, of the Majestic Co., near Milford, a strike was made this week in the main tunnel, opening up a body of bornite and black sulphides 4 feet wide. The main tunnel is in 230 feet, reports Foreman Price, and 162 feet more will bring it to the shaft. The winze from the tunnel level is down 18 feet. Crosscut No. 1 is in second-class ore 30 feet wide. The shaft is down 150 feet and showing black sulphide. A 34 H. P. hoist and galloos frame are being set up. A self-dumping skip will be used and an ore bin of 300 tons capacity built. At the smelter the structural work is about completed, says Manager Farish.

GRAND COUNTY.

Work was started last week on the Mineral Mountain tunnel, near Basin, in charge of J. McMahan, one of the owners. It is the intention to drive ahead until they cut the Sky Lark vein, which will be 50 feet from the breast, now in 300 feet. The Sky Lark shows gold and copper ore on the surface.

The Grand View M. Co. will resume by April 1st with tunnel work on its group on Horse mountain, near Basin, and continue the same until it reaches the Lincoln vein at a depth of 500 feet.

The mines and the smelter of the Paradox-La Sal Co. at Basin La Sal are in operation. Their ores carry silver and copper.

The Tornado-Indiana Co. at Basin will be ready for operations on April 1.

W. J. Gardner & Co. of Cripple Creek, Colo., are driving a tunnel on the Gold bill group, adjoining the Iowa on the west, near Basin. They are drifting in on the Iowa vein 1200 feet west of the Iowa tunnel.

A new company has been formed to work on Grouse mountain, near Basin, on property forfeited last year by the Josephine Copper Co. of Denver, Colo. The company is the Grouse Mountain M. & S. Co. of Huntington, W. Va., with W. R. Wheat as resident manager.

IRON COUNTY.

Manager Parker of the Ophir M. Co. mines and mill at Stateline says the mill will be remodeled and a cyanide plant installed.

JUAB COUNTY.

The Centennial Eureka of Tintic district, near Eureka, is to be equipped with an independent electric lighting plant capable of supplying 400 lights. Underground as well as the surface will be provided with electric light. Preparations are being made to resume sinking the shaft below the 1400-foot level, 500 feet, and a station is being cut.

The shipments from Tintic district, around Eureka, last week amounted to 126 cars of ore, as follows:

	Cars.
Centennial-Eureka	45
Carisa	2
Dragon Iron Mine	23
Eagle and Blue Bell	2
Gemini	6
Grand Central	24
La Clede	1
Lower Mammoth	4
Martha Washington	2
Mammoth	9
Noon Iron Mine	2
Uncle Sam	1
Yankee Cons.	5

Superintendent T. Weir is taking out copper-silver-gold ore in driving a 200-foot upraise from the 500-foot level in the Morning Glory of the La Clede M. Co., near Eureka.

The Lower Mammoth has made a contract with the smelters for a large tonnage of ore that carries 50% iron, ten ounces silver and 80 cents gold, of which the initial shipment of three cars was sent out last week. Superintendent Ball also shipped a 30-ton lot of 50-ounce silver ore from the 1050-foot level of the east fissure.

Manager L. E. Riter of the Dragon iron mine, near Eureka, says the quarry

has been worked as deep as it is practicable, and the iron ore will be hoisted through the 600-foot shaft sunk two years ago.

SALT LAKE COUNTY.

At the United States smelter at Bingham the management has given orders to double the capacity of the ore bins, which are at present 780 feet long and 25 feet high. The receipts of ore from the Centennial Eureka and from their Bingham group are increasing.

The "independent" smelters of the Salt Lake valley forwarded to the Eastern refineries this week approximately 700,000 pounds of copper bullion. The United States shipped three carloads (185,261 pounds), the Highland Boy five cars (300,000 pounds), and the balance by the Bingham Con.

SUMMIT COUNTY.

Superintendent Turner of the J. I. C. mine at Park City says the shaft is down 420 feet and being sunk at the rate of 5 feet a day.

Ad Utah

TOOELE COUNTY.

The Lucy L. M. & M. Co. has incorporated to operate the Lucy L. group of four claims in the Clifton district, near Ibapah. C. H. Wilson is president and F. L. Wilson secretary and treasurer.

A body of copper ore has been struck at 250 feet in the shaft of the Climax mine, owned by J. P. Gardner et al., in Deep creek, near Ibapah, in Clifton district.

WASHINGTON.

FERRY COUNTY.

The Gold King mine, on Upper Lambert creek, near Republic, has been bonded to J. D. Harper for \$10,000 by the Gold King M. Co., for six months. T. M. Hammond, Jr., is president of the company. The Gold King adjoins the Belcher.

C. T. Bliss of Spokane has an option on the Lone Pine-Surprise mine in San Poil gulch, north of Republic, for \$150,000. Machinery will be installed and development work increased.

STEVENS COUNTY.

The Gold Bug M. Co. of Tacoma has resumed work on the Gold Bug at the head of Pierre lake, near Bossburg. The shaft down 175 feet will be sunk to 300 feet. G. Bishop is superintendent.

J. W. Macdonald is developing the Macdonald group, 1 mile west of Bossburg. He is driving a tunnel in which he has cut two veins, both carrying values in gold and nickel.

The Minorca mine, in Flat Creek camp, near Ryan, has begun ore shipments.

FOREIGN.

AFRICA.

GOLD COAST.

The Asbanti Gold Fields Corporation reports that during January 2600 tons from the Obuassi mine and outside development were crushed, producing 2810 ounces.

The Asbanti Sansu crushings for January were 1210 tons, which produced 1260 ounces. The tallings have increased in value from 3 dwt. to 5 dwt.

RHODESIA.

The Eagle Vulture in January produced 975 ounces from 1392 tons.

At the Red and White Rose the January report was: Mill ran thirty days, producing 2179 ounces from 3619 tons crushed; recovered by cyanide, 431 ounces from 3257 tons treated; total yield, 2610 ounces.

At the Rezena the January result was: Crushed, 2425 tons, recovering from mill 837 ounces fine gold; from tallings by cyanide, 84 ounces fine gold; total, 921 ounces fine gold.

TRANSVAAL.

A late report on the labor question on the Rand is as follows. The native labor statistics for January show lower figures than those of any month of 1902 except February, when the Native Labor Association was formed. The total number of natives brought in was 3875, the greatest decrease being in the supply from the east coast, which was less by 914 than that of December. There were increases in the supplies from Zoutpansberg, the Low Country and Mozambique; 45,068 natives are now working in the gold mines and 7395 in the coal mines.

A commissioner has been appointed to investigate Chinese labor in China, with a view to its employment in the mines of the Rand. He will visit California to inquire into the methods of working the Chinese in that State.

AUSTRALIA.

The gold output for Australia in 1902 shows a marked increase over that of 1901.

The production of the several States and colonies was as follows:

COMPARATIVE STATEMENT IN FINE OUNCES.

State and Colony.	1901. Fine Ounce.	1902. Fine Ounce.	Inc. Fine Ounce.	Dec. Fine Ounce.
West. Australia.....	1,708,417	1,867,099	168,682
* Victoria.....	730,453	729,299	1,154
Queensland.....	598,362	623,331	24,969
New Zealand.....	412,877	458,933	46,056
New South Wales.....	216,888	254,435	37,547
	3,662,017	3,893,027	231,010	1,154

Net increase in fine ounces for 1902, 271,010
* Valued at \$1 per ounce.

BRITISH COLUMBIA.

(Special Correspondence.)—Since the beginning of the year five carloads of ore have been sent to the Nelson smelter from the Hunter V. mine, near Nelson—a total of 100 tons. This ore is being raw-holed at the rate of six tons a day. C. Wolfe, manager of the Foghorn mine, on Wild Horse creek, near Nelson, reports a strike of 18 inches of sulphide ore in the crosscut tunnel, in 25 feet. Drilling will continue until the main vein is struck. The heavy fall of snow this year is hampering the Golden Monarch M. Co. in its working on the Foghorn, and has obliged them to reduce their working force, due to the difficulty of getting in supplies.

Roseland, Feb. 21.

The Bureau of Provincial Information has issued the following figures of ore tonnage for 1902:

	Tons.
Grand Forks, Kettle River and Osoyoos divisions.....	525,000
Trall creek.....	340,000
Slocan and Ainsworth.....	30,000
Nelson.....	80,000
Coast district.....	25,000
East Kootenay.....	20,000
Other districts.....	25,000

Total.....1,045,000

The Mother Lode smelter of the British Columbia M. Co., at Greenwood, will double its capacity during the coming year.—The Standard Oil Co. are reported to be buying coal and iron in Nicola valley.—Free gold quartz has been opened at the Coronation mine, eight miles south of Gerrard, says the Prospector.

F. C. Green is at Camhorne surveying for the site of the Eva stamp mill and laying out the tramway line. The Calumet & B. C. Gold Mines, Ltd., at Camhorne, will haul their stamp mill in over the snow this winter, and the management state that as soon as the necessary data for the contract is secured the contract for the tramway will be let.

The Silver Gleaner, on Bear creek, in the Slocan division, is shipping weekly. The American Boy has contracted to ship a portion of their ores to smelters of the American S. & R. Co., the first contract made in the Slocan with this smelter.

The Flesher Malden has contracted with the Trall smelter for treating 1000 tons of high-grade ore. The ore averages 150 ounces silver, 6% lead and 12% zinc. The main vein and a large body of ore have been struck in tunnel No. 8, of the Payne mine. This adds 400 feet of stoping ground to this property.

Managing Director G. B. McAulay, of the Cariboo M. & M. Co., Ltd., mines at McKinney, in his annual report says there was mined and milled during the year 11,414 tons of ore from the Cariboo claim, 4100 tons from the Okanogan, 100 tons from the Saw Tooth, a total of 15,614 tons. The average value of the ore was \$9.65 per ton, 69.8% of which was extracted as free gold by amalgamation, 17.4% obtained in the concentrates, and \$1.27 per ton was lost in the tailings. During the year 1040 feet of drifts were run and 190 feet of upraises made.

The Velvet mine, near Roseland, is shipping forty tons per day and has started to stope level No. 5.

Shipments of ore from the Roseland camp for the week ending Feb. 21st were: Le Roi, 3730; Centre Star, 1310; War Eagle, 1110; Glant, 40; Velvet, 150; Le Roi No. 2, 385; total for week, 6725; year to date, 51,916 tons.

Returns from the Ymir mines show a net profit for the month of \$10,000, the highest since May last.

The Spyglass mine on Popular creek, near Lardeau, is producing silver-gold ores. It is owned by J. Winquist & Co. and is 11 miles from the line of the Lardeau railway. Assays show 1500 ounces silver and \$80 gold.

D. Cameron of Ymir, superintendent of the Union Jack mine of the Active G. M. Co., says at 165 feet in, on the lower tunnel on the Queen vein, a shoot of galena 4 feet wide has been struck, which averages \$25 per ton. Operations on the Union Jack vein are stopped pending the completion of the electric plant, which will be ready next week.

The Granby Co. has bought the Iron-

sides fraction claim, adjoining the Banner of the Granby group, and was secured largely for its timber. The tilting reverberatory furnace at the Granby smelter is in operation, being used as storage for molten matte, which is drawn off and used in the converters as occasion may require.

The Cariboo mine, Camp McKinney, earned \$136,000 last year from the proceeds of ore treated. Of this sum \$60,000 was spent on development work, \$50,000 applied to payment of dividends, and the balance placed in the reserve fund.

The Giant mine has been compelled to close down. The Trall smelter declined to accept its ore until the coke famine is relieved. Otherwise the local mines are not affected, as yet, by the fuel situation.

Up to the 21st inst. 550 members have enrolled in the Provincial Mining Association, of whom more than half are working miners.

CANADA.

ALBERTA.

J. J. Fleutot, superintendent Frank coal mines, on the Alberta side of the Crow's Nest, says they will install fifty coke ovens at Frank this spring. These ovens will not be of the beehive pattern, but built on a plan by which the coal in the course of the process is carried through a number of chambers. By this method, says Fleutot, the process only takes twenty-four hours, instead of seventy-two, as with the beehive oven. These ovens will each produce three tons of coke per day.

MEXICO.

CHIHUAHUA.

The second payment of \$350,000 gold is to be made on the San Francisco del Oro mine, near Parral, on March 1. This company also owns the La Union mine near Parral. G. Parral, of Parral, is manager.

D. H. Moffatt of Denver Colo., is reported to have bought the mines of the Batopilas M. Co., at Batopilas.

GUANAJUATO.

Manager Bryant of the La Luz Mines Co. of Denver, Colo., operating near Guanajuato, reports ore showing in fifteen different places in the three mines of their group. One of the veins runs 8 feet in width. The company is at present doing development work only and has 300 men at work. The ore being taken out in the course of development runs \$20 per ton in gold. The company plans to erect a 100-ton cyanide mill this spring. A profit of \$10 per ton is being made on the ore removed, but with the ore treated on the ground this profit can be increased to \$15 per ton, says Bryant. The power plant that is to supply the district with electric power will be ready to start up by August and the La Luz Co. will then equip its properties with electric hoists, pumps, etc. It will use at the mine and at the mill 600 H. P. One year ago the Sirena mine, owned by the Guanajuato Con. M. Co. of New York, was the only property being operated in this district. Boston parties have bought the Bolanitis mine. A company has been formed in New York to operate the Carmind, a former producer. Chicago men have bought the Cubo. D. G. C. MacNeill owns, and operates the Santa Anita. The Cedro mine is being operated by native Mexicans.

JALISCO.

The lixiviation plant of the San Vicente M. Co. at Ameca is in operation.

LOWER CALIFORNIA.

The Peninsula C. & S. Co. has bought the Santa Maria group of claims, near San Quintin, 15 miles south of San Julio canyon, and has sixteen men developing by shaft and crosscutting. A crosscut at one point opened 20 feet of copper ore, some of it carrying gold. Dikes cut the country in a northeast by southwest direction, and the ore is found near these. The mines are 18 miles from the Pacific ocean. The same company is working on the Julius lease, where 3000 feet of development has been done and ore of medium grade blocked out. The Canary Bird, 2 miles from the Julius Caesar, being developed at the 200-foot level, carries glance ore, but, unlike the Santa Maria group, neither the Julius Caesar nor Canary Bird carry gold or silver. The same company is developing the Columbia, a gold property near San Andreas. The McAnaney mill, near Jacalitas, back of Ensenada, has been bought by the Peninsula Co. and a site for a copper smelter has been secured at San Quintin. G. P. Brown of Los Angeles, Cal., is general superintendent.

The Paderra Onyx Co. has six teams hauling onyx to the beach at Point Santa Catarina, and from there it is shipped to San Diego, Cal. One piece weighing six and one-half tons was recently shipped.

J. W. Dawson of Los Angeles, Cal., representing Eastern men, has bought a

group of five claims in a new section of the peninsula known as Chapalo.

SONORA.

The Lloyd Bros. & Co. are developing the Plomosa de Santa Ana mine, 12 miles south of Trinidad. They have a silver-lead ore with values in gold and copper. Shipments will begin next week.

The Anglo-American Copper Co. have men at work on their gold and copper properties in the Santo Domingo mountains, south of Cananea, near Bacoachi. The company has 200 pertenencias, four tunnels have been driven, and the ores show iron, copper, gold, carbonate of lead and zinc.

Near Hermosillo the El Majin C. Co. is preparing to begin operations on a large scale.

NICARAGUA.

There are in the republic of Nicaragua forty-one mines of which official record is kept. During 1902 these produced a total of 78,000 ounces, valued at \$1,326,000. The ore is sulphide. The country rock is sandstone, volcanic rock and granite. In the Department of Leon and also in Matagalpa, the gold is very fine, occurring in white, chalky soft rock, and is extracted by the cyanide process. In New Segovia and Prinzapula, on the branches of the Rio Coco and Prinzapula rivers, some placer mining is done on a small scale, and some nuggets of five ounces have been found.

SALVADOR.

In the department of Morazan the Loma Larga, owned by the sons of ex-President Mariscal Santiago Gonzalez, consists of 10,000 acres of land, divided into four mineral zones. The principal vein is Loma Larga, silver and gold, averaging \$20 gold. This vein is 3 feet wide. The principal shaft is 393.6 feet deep and the main level 1640 feet long. About 30,000 tons of ore have been taken out of this vein. Water has now prevented further working. The San Francisco vein is 6.5 feet wide and runs \$10 per ton, silver and gold. The gold is free. The quartz is soft, a man extracting with a bar from six to eight tons per day. The main shaft is 229.6 feet deep, with 1640 feet of drifts. The Mantos del Socorro and De la Senora are most worked at present and run \$12 gold per ton. At the present time 600 tons of ore is treated monthly by the cyanide process. One hundred and fifty men are employed, all natives. The capacity of the plant is forty tons per day.

SIBERIA.

Gold mining in the Primorski region is divided into two parts—the northern, on the Amur river and the Okhotsk sea, and the southern, on several little rivers along the South Ussuri district and the island of Askold. Mining has increased in the former since the construction of the Ussuri & Transbaikalian Railroad. Trial excavations are made at a distance of 1 verst (0.663 mile) apart. The whole area is divided into triangular lots, formed by the lines of pits, and draining canals are dug and the necessary buildings are constructed. The work begins with stripping, by hand digging, horse cars carrying the turf away; but recently they have begun to wash the turf away by ground sluicing. A workman is paid from 61.2 to 92.7 cents a day. The washing is effected by barrel engines moved by locomotives. The richest gold layers in the South Ussuri region have been worked by the ancient Chinese processes. The lack of technical knowledge in gold mining is the principal reason why its development is so slow. The chief gold mining works in the province of Primorski were established during the last ten years, and a great number of gold veins of this region are not yet worked.

PERSONAL.

J. M. FORD of Phoenix, Ariz., is in New York.

A. J. OREM of Salt Lake has gone East on mining business.

P. A. H. FRANKLIN of Salt Lake City, Utah, is in Boston, Mass.

R. G. WILSON has returned to Salt Lake City, Utah, from California.

E. F. ADAMS, a mining man of St. Louis, Mo., is in San Francisco, Cal.

E. H. RANDELL of the Denver, Colo., Mining Reporter, is in San Francisco, Cal.

J. A. EDMAN, a pioneer California miner, is in San Francisco from Plumas county, Cal.

MANAGER PARKER of the Ophir M. Co. at Stateline, Utah, has returned from the East.

J. R. LEONARD of Pittsburg, Pa., has recently been at Octave, Ariz., and is now in California.

F. F. THOMAS, general manager of the Gwin mine, Calaveras Co., Cal., is in San Francisco, Cal.

R. HECKSHER, of London, England, interested in the Clifton Con. M. Co., is in Clifton, Ariz.

H. M. GORHAM is superintending operations on the Brunswick lode, near Virginia City, Nev.

MR. MCCLINTOCK of F. W. Braun & Co. has returned from San Francisco to Los Angeles, Cal.

C. A. ROSS, president of the Standard copper mines, is in Clifton, Ariz., from London, England.

W. E. BURK of Louisville, Ky., has been making mine examinations in Graham county, Arizona.

H. T. POWER, manager of the Hidden Treasure mine, in Placer county, Cal., is in San Francisco, Cal.

A. J. ANDREWS of Montreal, Canada, part owner of the Dollie B mine, at Leadville, Colo., is at the mine.

J. B. HUBINGER and J. W. WHITMORE have returned to New Haven, Conn., from Phoenix, Ariz.

MANAGER R. G. WILSON of the New York Bonanza has returned to Salt Lake City, Utah, from California.

C. A. ROSS, president of the Standard Copper Co., near Clifton, Ariz., has arrived from London, England.

A. M. RUCKER is superintendent of the Nevada Con. G. M. & M. Co. at King Flats, near Central City, Colo.

PRESIDENT SOPERS, of the Bayard M. Co. at Golden, N. M., has been visiting the mines from Toronto, Canada.

F. B. COOK has returned to Salt Lake City, Utah, from Montana, where he has been examining mining properties.

S. A. PARNALL, general manager of the Burrage mining interests at Terrazas, Chihuahua, Mexico, is in Michlgan.

P. W. FLEMING and J. B. COPLIN of Tucson, Ariz., have been examining the Golden Wonder mine in Gila Co., Ariz.

A. F. HOLDEN of Salt Lake City, Utah, managing director of the United States M. Co., is visiting at Santa Barbara, Cal.

H. H. HARVEY, mining engineer, has returned to Oakland, Cal., from making mine examinations near Jamestown, Cal.

H. A. SMITH has returned to Salt Lake City, Utah, from Elmore county, Idaho, where he is interested in the Ella Hill group.

D. S. SANFORD of the Shorty Hope M. & M. Co. and M. J. Goldner, treasurer of the company, are in Ashland, Or., from New York.

ASSISTANT SUPERINTENDENT DUNYAN, of the Daly-West, has resigned that position to take charge of another Park City property.

MANAGER W. A. FARISH of the Majestic Co., near Milford, Utah, is examining mines in Arizona, of which he is consulting engineer.

G. E. VOORHEES, JR., of Santa Barbara, Cal., principal owner of the Las Vigas mine at Coyame, Chihuahua, Mexico, is visiting the mine.

A. C. ELLIS of the Salt Lake-Tonopah M. Co. returned to Salt Lake City, Utah, last week after an absence of several weeks in Nevada and California.

W. F. SNYDER of the Western Exploration Co. has returned to Salt Lake City, Utah, from an inspection of the company's California properties.

R. HANLEY, formerly superintendent of the Niagara mine at French Gulch, Cal., is superintendent of the Horseshoe M. Co., near Deadwood, S. D.

R. WILLIS, manager of the Coronation M. & M. Co., near Idaho Springs, Colo., has gone East to attend a meeting of the stockholders of the company.

P. L. BANNAN is president and manager of the Pacific Gear & Tool Works of San Francisco, Cal., and P. Lawlor is secretary of the same company.

H. BROWNLEE of New York, of the Bingham & New Haven Co., accompanied by Manager F. Benedict is inspecting the Frisco-Zelnora mines near Frisco, Utah.

C. O'KEEFE, president and manager of the Sonora M. & M. Co., returned this week to the mine, 60 miles northwest of Magdalena, Sonora, Mex., from Phoenix, Ariz.

C. R. DOWNS, superintendent of the Bunker Hill mine near Amador City, Cal.,

has returned from San Francisco, Cal., to his home at Sutter Creek, Cal.

F. L. SLOCUM, vice-president of the Miami M. Co. of North Carolina, is in San Francisco, Cal., and will examine some of the mines of Amador county, Cal.

S. L. PEREMAN of St Petersburg, Russia, a large iron founder, and D. Grassmoff, consulting engineer, are in northern California inspecting mines and mining methods.

MANAGER H. LA MONTAGUE of the Sultana mine, near Hillside, Ariz., is at the mine overseeing the erection of a stamp mill and cyanide plant for that property.

BURDETTE MOODY, chief engineer of the Homestake Co. at Lead, S. D., has resigned to associate himself with Henry Schmitzel, E. M., to give attention to private interests.

W. H. MCCLINTOCK, president and manager of the Don Pedro M. Co., operating near Don Pedro, Tuolumne county, Cal., has established his headquarters in San Francisco, Cal.

J. C. KORTZ of Cleveland, Ohio, president of the Ohio & Colorado Smelting Co.; J. M. Thomas, treasurer, and T. Goodwin, general manager, were visiting the mines of Leadville, Colo., this week.

G. J. JOHNSON, superintendent of the Colorado Fuel & Iron Co. mines at Madrid, N. M., has been transferred to Starkville, Colo., and Superintendent Lamh, formerly of Starkville, takes charge at Madrid.

PRESIDENT G. W. HUDDLESTON, of New York; treasurer, E. A. Godding, of New York; D. G. and C. C. Edwards, of Providence, R. I., of the Sultana M. Co., are visiting the mines of the company at Angels, Cal.

Commercial Paragraphs.

W. H. CHRISTIE has removed his office from 314 Pine St. to 615-16 Hayward Bldg., San Francisco, Cal.

THE Union Ore Extraction & Reduction Co., Denver, Colo., say they have installed their new plant and are now running full in every department.

F. C. COOLEY has been appointed agent General Chemical Co. of Chicago and New York, and Baker & Adamson Chemical Co., Easton, Pa., with office at 1752 Champa street, Denver, Colo.

THE Dyer Mill Co., 240 Montgomery street, San Francisco, Cal., are putting a cannon ball mill on the market that they say will work wet or dry equally well; also furnishing small mills for prospecting purposes.

THE Risdon Iron Works of San Francisco, Cal., report having sent the past week to the Tenderfoot G. M. Co. at Joseph, Or., a complete 20-stamp mill, with 1000-pound stamps, eight 6-foot Johnston concentrators, water power and a saw mill.

THE Paraffine Paint Co. of San Francisco, Cal., have moved to No. 24 Second street, where they now have more commodious office rooms, in keeping with the present expansion of their business. They have bought additional land adjacent to their factory site at Paraffin, near Emeryville, Alameda county, Cal., and have erected several large brick buildings and greatly increased their capacity for manufacturing P. & B. roofings, building papers and paints.

THE Pacific Gear & Tool Works has incorporated at San Francisco, Cal., and succeeds to the business and property of P. T. Taylor & Co. The incorporators are P. L. Bannan, president and manager; P. Lawlor, secretary; F. Gottfried, J. H. Folles, and T. Butcher. Their machine shop at 523 Mission street is well equipped with the latest milling and gear-cutting machines. As gearing forms a prominent part of the work done by the company, correspondence relative to same is solicited and estimates will be furnished.

Books Received.

"Electricity as Applied to Mining" is the title of a new book issued by D. Van Nostrand Co. of 23 Murray street, New York. It handles the subject systematically and thoroughly, from the first introduction of electricity in mining operations twenty-five years ago up to the present. The book is the joint effort of Arnold Lupton, G. D. Asplund, Paw and Herbert P. Kinn, noted electrical and mining engineers. It contains 170 illustrations and 280 pages. Bound in cloth. Price \$3.50.

Catalogues Received.

Catalogue No. 17 of the Weber Gas & Gasoline Engine Co. of Kansas City, Mo., in black and carmine, gives much information not only regarding that class of engines, but on gas power in general and its practical application. The cuts are new, the tables and descriptive matter well prepared, and 105 testimonials from pleased patrons give endorsement to the efficiency of their manufacture.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market St., S. F., has official reports of the following U. S. patents issued to Pacific coast inventors:

FOR THE WEEK ENDING FEBRUARY 17, 1903.

- 720,994.—MAP.—A. von Babo, Seattle, Wash.
 721,000.—R. R. SWITCH.—W. J. Bell, Los Angeles, Cal.
 720,889.—OIL BURNER.—A. H. Calkins, Santa Monica, Cal.
 720,895.—VISE.—E. R. Cook, Sacramento, Cal.
 720,783.—TELEPHONE MOUTHPIECE.—C. W. Clough, Watsonville, Cal.
 721,022.—HORSE CONTROLLER.—C. B. Corl, Riverdale, Cal.
 721,023.—GREASE CUP.—F. B. Cosper, Seattle, Wash.
 720,897.—MOTOR POWER.—F. A. Creed, Whatcom, Wash.
 720,799.—PLASTER.—H. M. Hammore, Los Angeles, Cal.
 720,814.—BRAKE BLOCK.—P. L. Jones, S. F.
 720,815.—SAWMILL.—W. E. Jones, Clear Lake, Wash.
 721,051.—TOY BALLOON.—A. J. King, Los Angeles, Cal.
 720,700.—GRAPPLE.—W. Kirry, Blue Lake, Cal.
 720,938.—SHADE BRACKET.—E. H. B. Lindhorst, Sacramento, Cal.
 721,067.—HOIST.—W. L. McCabe, Seattle, Wash.
 720,944.—SAW.—J. Meklejohn, Sedro Woolley, Wash.
 720,948.—DIEK PLOW.—J. P. Mulrony, Plaza, Wash.
 720,839.—HORSE BLANKET.—E. C. O'Neil, S. F.
 720,840.—LOADING DEVICE.—T. M. Park, Darrington, Wash.
 720,950.—LOADING DEVICE.—T. M. Park, Darrington, Wash.
 721,090.—WAVE MOTOR.—F. H. Reed, Claremont, Cal.
 720,853.—ROCK CRUSHER.—Spargo & Rose, Doble, Cal.
 720,750.—WATER WHEEL.—E. E. Speigle, Stockton, Cal.
 720,984.—TACKLE BLOCK.—A. H. F. Stranh, Portland, Or.

Notice of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

WAGON BRAKE BLOCK.—No. 720,814. Feb. 17, 1903. P. L. Jones, San Francisco, Cal. This invention consists in a means for mounting the block upon a supporting and actuating shank, with a spring-adjusting attachment therefor, and means for regulating and limiting the movement of the block upon the shank. This device may be equally well attached to iron or wooden brake blocks and may be fitted to blocks of any size, the spring being, as before stated, reversible, so that one pattern serves for both right and left slides, and the movement of the brake block is limited in both directions by the lugs and adjusting screw. The wide lower end of the collar forms a sufficiently long bearing of the screw to prevent its becoming loosened in its threads by its use, and this portion also serves to steady the brake block or plate and prevent its tilting or wobbling upon the shank. The lugs at opposite ends of the screw prevent its working out and being lost.

ATTACHMENTS FOR HORSE BLANKETS.—No. 720,839. Feb. 17, 1903. E. C. O'Neil, San Francisco, Cal. The object of this invention is to provide a simple, durable and adjustable securing device by which the blanket may be held down over a horse's rump to prevent the blanket being disarranged or blown off when the horse is exposed to winds or storms. The novelty of the device resides particularly in the position of the points of attachment of the strap, and means by which the strap ends are resiliently supported in order to allow the blanket to be quickly put on or taken from the horse and to accommodate for the natural movements of the horse while blanketed.

CONCAVES FOR ROCK CRUSHERS.—No. 720,853. Feb. 17, 1903. John D. Spargo and G. W. Rose, Doble, Cal. This invention relates to improvements in rock crushers of the gyratory type, and pertains particularly to the concaves or grinding surfaces thereof. It consists in making these concaves rectangular or with parallel side edges instead of wedge-shaped and employing keys to lock the concaves together, said keys being wedge-shaped and having their lower ends thicker than their upper ends. When a set of these concaves have become worn at one end, the concaves may be reversed, thus effecting a saving of practically one-half in the expense of maintenance of a breaker. In mining operations where low milling expenses are of importance this saving becomes appreciable.

ANTISEPTIC ATTACHMENTS FOR TELEPHONE MOUTHPIECES.—No. 720,783. Feb. 17, 1903. C. W. Clough, Watsonville, Cal. The object of this invention is to provide a device which can be quickly attached to any ordinary mouthpiece, which shall in no wise interfere with the transmitting quality of the telephone, and which shall have the property of destroying bacteria and other germs expelled by the breath. These bacteria and germs often render promiscuous use of telephones a menace to health. The invention consists of an antiseptic or sterilizing adhesive water-soluble or other means of attachment to the mouthpiece than its inherent adhesiveness.

Latest Market Reports.

SAN FRANCISCO, Feb. 27, 1903.

METALS.

SILVER.—Per oz., Troy: London, 22s 3d (standard ounce, 925 fine); New York, 48¢; refined (1000 fine): San Francisco, 48¢; Mexican dollars, 38¢ @ 39¢ San Francisco, 38¢ @ 39¢ New York.

COPPER.—New York: Standard, \$12.62½; Lake, 1 to 3 casks, \$13.12½; carload lots, \$12.75; Electrolytic, 1 to 3 casks, \$13.37½; carload lots, \$12.50; Castling, 1 to 3 casks, \$12.75; carload lots, \$12.50. San Francisco: \$14.00. Mill copper plates, \$17.00; bars, 18¢ @ 24¢. London: £59 1s 3d spot per ton.

Copper, as predicted, has reached and passed the 13 cent mark in New York, and, judging from the condition of the market and what can be learned of supply on hand, the price is likely to go higher. It is stated that there is not over a single month's supply on hand; but this is not considered a surplus.

L. Vogelstein of New York City furnishes the following figures of German consumption of foreign copper for January-December, 1902, compared with the same period of 1901 and 1900:

	1902.	1901.	1900.
Tons.	Tons.	Tons.	
Imports.....	80,417	63,155	88,108
Exports.....	8,903	10,277	10,960

Foreign.....71,514 52,878 77,146

LEAD.—New York, \$4.12½; Salt Lake City, \$3.50; St. Louis, \$4.00; San Francisco \$4.50, carload lots, 4½¢ 1000 to 4000 lbs.; pipe 5½¢ sheet 6, bar 5½¢; pig, \$4.75. London: £12 3s 9d per long ton = 2.610 per lb.

SPELTER.—New York, \$5.05; St. Louis, \$4.60; London, £21 10s per ton; San Francisco, ton lots, 6½¢; 100-lb lots, 7c.

ANTIMONY.—New York, Cookson's, 9½¢; Hallett's, 8½¢; San Francisco, 100-lb. lots, 10c; 300 to 500 lbs., 11c; 100-lb. lots, 13¢ @ 15c.

TIN.—New York, pig, \$29.50 @ 29 75; San Francisco, ton lots, 31c; 500 lbs., 31c; 200 lbs., 31½¢; less 32c; bar tin, 31c @ 37½¢. London, £133 15s spot.

PLATINUM.—San Francisco, crude, \$18.00 @ 19.00; New York, ingot, \$19.00 per Troy oz. Platinum ware, 75¢ @ 80¢ per gram.

QUICKSILVER.—New York, \$45.50 @ 46.00; large lots: London, £8 15s; San Francisco, local, \$45.00 @ 46.00; 70¢ lbs.; Denver, \$49.50. Export, \$43.50.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½¢; extra, 17½¢; genuine, 35c; Eclipses, 37½¢.

ALUMINUM.—New York, No. 1, 99¢ pure ingots, 35c; No. 2, 90¢, 30c to 34c.

SOLDER.—Half-and-half, 100-lb. lots, 20c; San Francisco, Plumbers', 100-lb. lots, 16.65c.

NICKEL.—New York, 50¢ @ 60c @ 70¢; ton lots, 45¢ @ 48c.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$23.10; gray forge, \$20.50; San Francisco, har, 3c @ 3½¢ in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$30.00; open hearth billets, \$31.50; San Francisco, bar, 7c to 12c per lb.

CHICAGO CURRENT QUOTATIONS.

Special rates for carload lots.

GENERAL SUPPLIES.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15¢; less than one ton, 17¢. No. 1*, 60%, carload lots, 13¢; less than one ton, 15¢. No. 1** 50%, carload lots, 11¢; less than one ton, 13¢. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2*, 35%, carload lots, 9c; less than one ton, 11c. No. 2** 30% carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 725 kegs, \$1.50 per keg; less car lots, \$2 per keg.

CAPS.—3x, \$5.50 per 1000; 4x, \$6.50; 5x, \$8; Lion, \$9, in lots not less than 1000.

FUSE.—Triple tape, \$3.60 per 1000 feet; double tape, \$3.00; single tape, \$2.65; Hemp, \$2.10; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 feet and up.

CANDLES.—Granite 6s, 16 oz., 40s., 10c @ 12c; 14 oz., 40s., 9c.

CEMENT.—Germania, \$2.50 @ 2.75; Hewmore, \$2.90; Trowell, \$2.90; Portland, \$2.50 @ 2.75 per bbl.

LIME.—Santa Cruz, \$2.25; Roche Harbor, \$2.25 per bbl.

OILS.—Lined, boiled, hbl., 56c; cs., 61c; raw, bbl., 54c; cs., 59c; Lucol oil, boiled, bbl., 50c; cs., 55c; raw, bbl., 48c; cs., 53c. Kerosene—Pearl, per gal., 22½¢; Astral, 22½¢; Star, 22½¢; Extra Star, 25½¢; Ecocene, 24c; Elaine, 27½¢; Water White, in bulk, 16c; Mineral Seal, iron bbls., 18c; wooden bbls., 21c; cs., 24c; Mineral Sperm, cs., 26½¢; Deodorized Stove Gasoline, bulk, 17c; do., cs., 23½¢; 86° Gasoline, bulk, 21c; do., cs., 27½¢; 63° Naphtha or Benzine, deodorized, in bulk, per gal., 16c; do., in cs., 22½¢; c. Lard Oil, E. W. S., bbl., \$1.00; cs., \$1.05; Neats-foot Oil, pure, bbl., 75c; cs., 80c; Sperm, crude, 50¢ @ 60c; Natural White, 65c; Bleached do, 70c; Whale Oil, cs., 50¢ @ 55c.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., per lb., 6½¢; in 25-lb. tin pails, 7c per lb. above keg price; in 1 and 5 lb. tin cans, 100 lbs. per case, 7c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6c; do. in kegs, 6½¢.

RED LEAD.—500 lbs. and over at one purchase, per lb., 6c; less than 500 lbs., 6½¢.

LITHARGE.—Pure, in 25-lb. bags, 8¢ @ 9c per lb.

BONE ASH.—Extra No. 1, 5¢ @ 6c per lb. No. 1, 4¢ @ 5c.

BORAX.—Concentrated, 7¢ @ 9c per lb.; powdered, 9¢ @ 12c; fused, 25¢ @ 30c.

BISMUTH.—Subnitrate, per lb., \$1.60.

BONE ASH.—4c @ 5c.

BORAX.—Crystal, 7c; calcined, 25c.

COPPER.—Sulphate, 5¢ @ 7c.

MANGANESE.—(90% and over) 7¢ @ 11.25.

MOLYBDENUM.—25c. 3/4 gramme; 1000 grammes=2½ lbs.

CHROMIUM.—(90% and over) per lb., \$1.25.

SODIUM.—Metal, 7¢ @ 11.25.

MERCURY.—Bichloride, 7¢ @ 10c, 80c.

PHOSPHORUS.—(American) 7¢ @ 11.00.

SILVER.—Chloride, 7¢ @ 11.00; nitrate, 55c.

URANIUM.—Oxide, 7¢ @ 11.25.

ZINC.—Metallic, chemically pure, 7¢ @ 11.25; dust, 7¢ @ 10c; sulphate, 7¢ @ 10c.

(These prices are wholesale, f. o. b. San Francisco, unless otherwise noted.)

WANTED.—PROSPECTORS AND LEASERS on private estate in California, 20,400 acres. Timber and water plentiful. The "GREAT STONEWALL" mine which has produced two million dollars on grant, which has never been prospected. For particulars, address

Usefulness of the Arrastra.

The most primitive mechanical device in the way of quartz-crushing machinery is the arrastra. In principle it is simple; in operation slow, but effective. It is the favorite resort of the miner who has rich gold rock but limited means to equip his property with machinery. The arrastra is usually built of stones—bottom and sides, and large hard rocks are selected to perform the function of pulverizing the ore introduced into the arrastra basin. Although simple in construction, the amount of material crushed and the percentage of extraction varies greatly with the same ore, depending on the experience or incapacity of the man in charge. He who does not know from careful instruction or long experience the secrets of the arrastra will crush much less and save much less than he who is familiar with its details of construction and method of operating. One important thing is to so dispose the "drags" that every portion of the basin is covered by each revolution of the upright shaft to which the "drag" arms are attached. Another feature worth remembering is to hang the "drags" by chains in such manner that their forward edges are slightly elevated, permitting the pulp to readily pass underneath. Some construct the basin with flat bottom, others incline the bottom from the center outward, and others from the edge toward the center. It is a close gold saver, and will often amalgamate an ore which cannot be satisfactorily amalgamated in a stamp battery, because of the condition of the particles of gold which are coated with silica or mineral oxide. This the abrasion of the arrastra quickly removes, brightening the gold and making it easy to amalgamate.

The arrastra has been usually the first "mill" introduced in new high-grade western camps. Often in the southwest, particularly in Arizona, New Mexico and southern California, these useful primitive quartz mills have been and are still numerous. They

may be operated with the minimum amount of water, and in many places large numbers of them may be found in a better or worse state of preservation, in the neighborhood of streams or springs, though no mines are near. Water being scarce at the mines the ore has been packed several miles to the arrastras located near the water. In Riverside county, California, there are over 100 of these old arrastra beds in the Gavilan district, grouped about springs.

The accompanying engraving is of a series of arrastras at Guanajuato, Mexico. Each arrastra is operated by a mule (blindfolded). This is the universal custom, as it has been found that animals will work more steadily while walking in a circle when blindfolded than otherwise. The ore is introduced to these arrastras through a hopper from a car running over-

head along the entire series. There are no arrastra establishments operated in the United States on so large a scale as the one illustrated here, but the arrastra is found in the Southwest running by gasoline engine, by steam and water power, as well as by animal power. So satisfactory is the arrastra in its work as a gold saver that the principle of its operation has been introduced into various forms of continuous crushing rotary mills. The principal difference between an arrastra and a Chilean mill is, that in the latter solid wheels of stone are substituted for the flat drags of the arrastra. These wheels are placed on a rigid axle, and in making a revolution of the basin the wheels grind as well as crush the ore. The Chilean mill also has its imitators in iron and steel. They are suited to fine crushing and grinding.

The capacity of the arrastra, like all other quartz-crushing machinery, depends on many factors. The most important are the size and construction of the arrastra, and the friability of the quartz, and to a great extent upon the size of particles introduced into the bed. Very hard quartz will crush much more readily if first calcined.

In the process of calcination the water contained in the rock, penetrating every microscopic crevice and vesicle, and often forming an essential part of the rock itself, is expelled. It is supposed that the pressure of steam generated by the application of heat causes the rock to disintegrate to a great extent, making subsequent pulverization comparatively easy. The burning also oxidizes the sulphides, thereby rendering the gold susceptible to amalgamation, and for this reason ore containing sulphides should be roasted.

Location by Agent.

Prospectors going into the newly discovered placer mines of Tanana district, Alaska, are complaining, it is reported, that Tanana creek and its tributaries are located from end to end by those first on the ground, who have taken up claims in the name of friends and relatives in the capacity of agents. This is just what may have been anticipated, for there is nothing in the Revised Statutes that prohibits one from securing a mining claim through the instrumentality of an agent. The title to mining property comes through compliance with certain conditions defined by the mining law, and one does not necessarily have to take the initiatory steps in securing the claim in person. In many cases the person in whose name a location is made may be totally ignorant of the transaction, but the law presumes that the act is done with his knowledge and consent, upon the general principle that a party is presumed to assent to a deed or other act manifestly in his interest. Claims so taken are subject to the operation of assessment and other laws governing mining claims the same as any other claims, and in the event of the failure to comply with the laws the claims may be taken by others.

As most mining properties in these days depend to a great extent upon the investment of large sums of money in equipment, and development for success, and as the individual prospector or investor is sometimes unable or unwilling to provide these essential factors in the conduct of the business of mining, the law permitting the taking of as many claims as one can properly "represent," or develop and exploit, seems to be not unwise. There are few syndicates or associations of large means which care to invest in a single claim, though eventually it is often found that the principal values are obtained from a single location. As a means of protection against the possible encroachment of neighboring interests, and also in the hope of extensive ore deposits being found, a

large area of ground is preferred by large investors.

With few exceptions those who are the first to reach a newly discovered mining field rarely are the ones to realize the greatest benefit from the dangers and hardships encountered. It is those who come later that have the better opportunities.

The Copper Market.

As predicted in these columns some weeks ago, copper has not only reached 13 cents per pound, but has passed that point, sales having been made in New York, the past week, at 13.75, and it is now safe to predict 14 cents copper within a reasonably short time, as there is nothing in either the market, the present production of the metal, the stock on hand or the wants of consumers to anticipate lower prices, for, in fact, a consideration of all these conditions plainly suggests the probability of higher prices. The rising price of the metal stimulates production, of course, but most of the large producers that can make profit at present prices are in operation, as well as some that are operating at a small loss. The range in price since 1898 has been notable, though being on an average about 12 to 13 cents. The lowest price within the period mentioned was 11 cents, obtaining in February, 1898, and the highest, 19½ cents, in April, 1899; but the fairly high price throughout this time has proven a great stimulus to the active development and equipment of copper properties, and no period in mining history has seen so many and such large undertakings inaugurated as within the period named. The wide range in price during the years mentioned has been due partly to manipulation by large interests, and partly to the natural course of events in the markets. At the time of the organization of the Amalgamated Association, April 29, 1900, with a capital of \$75,000,000, it was pointed out by the MINING AND SCIENTIFIC PRESS that this amount of capital was insufficient to control the copper market of America, to say nothing of dictating the price for the world. There were too many large conflicting interests—a struggle to sell all the copper produced, and no fixed price could be maintained.

While much distrust seems to have been engendered among large sellers of copper by the failure of certain producers to report their production according to understanding or agreement, or the suspicion that some others rendered fictitious reports, this seems to have been overshadowed by the actual operation of the laws of supply and demand, and under the stimulus of a heavy and continuous demand the market price is steadily advancing.

Silver in Mexico and China.

The gradual depreciation in the price of silver to its present value of 48½ cents per ounce has done much to stimulate gold mining. The sanguine ones who long hoped for better prices have long since given up that hope, and nothing now is anticipated for silver in the way of better prices. Mexico and China are striving to make some arrangement which will be advantageous to them. In the proposition recently submitted to the United States they practically ask that Mexico, and other countries desiring to do so, shall issue a new silver currency at the ratio of about 32 to 1, this currency to be maintained at a stated value by the governments interested controlling the quantity of currency coined and abolishing free coinage. These coins shall be accepted for public debts at gold parity, a gold exchange fund being maintained at the capitals of the countries entering into the agreement. The silver dollar of the United States, though containing only about 37 cents worth of silver, is maintained in value in this manner. Of course, in governmental transactions silver is not exchangeable for gold, excepting at hullion rates. The United States is only requested to give its moral influence to the plan, and not to enter into it further than that. Were Mexico, China, Siam and other countries at present giving serious consideration to their monetary systems to adopt the gold standard, it is difficult to say what effect it would have on the money markets of the world. It is doubtful if there is at present sufficient gold in existence to make this practically possible, and, in view of this fact, the proposed plan of Mexico and China seems to have much to recommend it.

Annual Assessment on Oil Claims.

Congress has had under consideration for some time an amendment of the law relative to annual assessment work on oil mining claims where the same are taken up under the revised statutes as placer mining claims. The bill as amended provides that where oil claims are located as placer claims the annual assessment work may be done upon any one of a group of claims lying contiguous, and owned by the same person or corporation, not exceeding five claims in all, providing that the labor will tend to the development or determine the oil-bearing character of such contiguous claims. The law now requires that upon each mining claim there shall be performed each and every year at least \$100 worth of work. The courts have held, with reference to lode mining claims, that this assessment work may be performed upon any one of the group of claims when it can be shown that the work is done to the direct benefit of all the claims in the group, but the land department of the Government seems unwilling to accept this ruling, and seems to be of the opinion that the annual labor upon placer mining claims must be done upon each of said claims. The bill passed the House of Representatives December 6 and is now before the Senate. It is believed it will pass the Senate without change. The necessity of such an amendment to the law is apparent, and is of great importance to the oil mining industry.

Mining Bureau Bill Killed.

A bill introduced in the Oregon Legislature creating a mining bureau, for the investigation and advancement of the mining interests of the State, passed both the Senate and Assembly, but was vetoed by Governor Chamberlain as too drastic in its provisions. The bill made the chief executive of the new department of mines not only an official whose province should be to investigate and report upon the mineral resources and industry of the State, but it also made him virtually an inspector of mines who would have authority to enter mines at any time, and approve or condemn methods of operating, machinery employed, etc. The leading mine owners and managers of the State petitioned the Governor to veto the bill, which, upon investigation, he did. A mining bureau, created solely for the purpose of investigating the mineral resources of the State, with the publication of official statistical and technical, as well as practical information concerning the same, would be of great value to Oregon, as it is to any State, but the need of an inspector of mines is not apparent. There are inspectors in several of the mining States, and there is about an equal number without them. Results do not show that mines are managed more carefully, or that there is a lesser number of fatalities—to the number of men employed—in those States having inspectors than in those operating without them.

THE government of India has issued a customs circular reducing the duty on crude petroleum having a "flashing test" of 150° or over to 5% ad valorem, provided it can be shown that the oil is to be used for fuel only. That there is any necessity for so high a "flashing point" has not been shown, though, as a matter of course, affording far greater security to the users of the oil. Millions of barrels of oil are annually consumed in safety where only ordinary precautionary measures are taken, the flashing point of which is far below 150°.

THE local papers of Wardner and other towns in the Cœur d'Alene district of Idaho report the merger of the principal lead-silver mines of that section, in which the American Smelting & Refining Co. are said to be an important if not the chief factor. The control of the lead industry in the Cœur d'Alenes will probably result in an apportionment of the output and possibly also higher prices for lead, as this section of Idaho produces more silver-lead ore than any other district or State in the Union.

AN attempt to pass an eight-hour bill for the benefit of underground mine workers in the Idaho Legislature was defeated in the Assembly, though passing the Senate. A similar bill became a law in Utah.

CONCENTRATES.

A DIRECT CURRENT of 500 volts would probably prove fatal to a human being.

SHELLAC makes an excellent insulator on wires of a newly-wound armature.

A DYNAMO will light from eight to twelve 16-candle power lamps per horse power; approximately allow 53 watts to each lamp.

AN object glass whose focal length is 72 inches, with an eyepiece of 2 inches focal length, will magnify an object thirty-six diameters.

A MINING LOCATION made on unsurveyed public land is valid. But a valid homestead location can not be made on unsurveyed public land.

THE longest electric transmission in the world is that of the Standard Electric Co. and Bay Counties Power Co., in California—220 miles.

MINERAL WOOL is mostly made from slag. About 40% of the annual product is derived from natural rock. About 4000 tons of mineral wool are yearly produced from slag in the United States.

A YELLOW PINE LOG has a resisting power to end crushing of from 4700 to 9800 pounds per square inch. Spruce ranges from 5000 to 7800 pounds, but spruce timbers will outlast yellow pine in resisting decay from effects of underground conditions.

TWENTY ONE minerals are known to contain zinc, but few are commercially valuable, their order of production being sphalerite, smithsonite, zincite and calamine. Not more than six minerals contain tin; cassiterite, the tin oxide, furnishing all the metal produced.

THE Catlin shaft, near Elandsfontein, Rand, is 8x28 feet, and 3950 feet in depth—the deepest in South Africa. At that depth the rock temperature is 80° F. At Turfontein a diamond drill struck the reef at a depth of 4800 feet, and a shaft is now being sunk to that depth.

CHILLED CAST IRON can be drilled if the chill is drawn. This can be done by laying the piece to be drilled in the forge, covering the spot to be drilled with sulphur and working the bellows slowly until the sulphur is burned off, when the drilling can be proceeded with.

FISH PLATES are advisable on outside tracks where there is heavy tramping; but underground, where the cars hold less than one ton and the tramping is done by men, they are an unnecessary expense. If the ties are substantial and good-sized spikes are used when the track is laid.

IRON SULPHIDES suspected of containing gold may be tested by giving the material a thorough roasting and subsequent grinding in a mortar with water. The gold may then be generally seen on panning, but even this test is not positive, as the gold may be present but be too fine to be seen.

SELENIUM is not a common mineral. It is reported to have been first discovered in the flue dust of the lead chambers of acid works in Sweden. In its properties selenium resembles tellurium. When heated it gives forth an odor resembling decaying borseradish. Arsenic when heated smells like garlic.

AN undeveloped mine must necessarily be an uncertain venture no matter what its surroundings may be. Each mine must make its own record and depend wholly upon its own resources, though frequently much consideration is given adjoining property, in placing a valuation on the undeveloped mine.

RAWHIDING is the principal means of ore carriage in the big places in British Columbia. The sacks of ore are securely enclosed in a rawhide and this is dragged by a horse over the snow. In the Lardeau particularly they accumulate their ore and wait for the deep snow and baul in the rawhide as described.

STEAM HOSE may be employed in connection with steam sinking pumps in mines; but "slipjoints" are superior, as the hose, if not kept under constant pressure, vulcanizes and becomes brittle, beside leaking badly at the couplings, and this leaking is difficult to stop. The pump can be handled better with the slipjoint.

THE ores of nickel number twenty-five, copper nickel, niccolite, the silicate, garnierite, millerite, nickel sulphide and smaltite, cobalt glance, furnish most of the nickel of commerce. There are ninety minerals containing iron. The oxides (hematite, limonite and magnetite) furnish nearly all the iron smelted from the ores.

APLITE is dike granite of uniformly fine grain and consisting of quartz, orthoclase and some plagioclase with little or no mica. Sometimes the masses are large, and in some instances quartz almost wholly replaces all

other constituents, forming a rock resembling quartzite. Rare instances are reported where this rock is gold bearing.

STEEL has been employed in sustaining mine workings, and under ordinary conditions answers admirably, but it is doubtful if its employment in swelling ground would be found satisfactory, as steel is rigid and will not bend, thus giving warning of the threatened collapse, which, should it occur, could not be anticipated as is the case where timbers are employed.

THE Colorado State mining law provides that no location certificate shall claim more than one location, whether the same be made by one person or several, and if it purport to claim more than one location, it shall be absolutely void, except as to the first location described, and if they are so described that it cannot be determined which was first located, then the location shall be void as to all.

STANNITE (tin sulphide) is comparatively rare, but occurs in some Cornish tin mines, and has been reported from the Etta tin mine, Black Hills, South Dakota, in small quantities. In New South Wales, at Howell, tin occurs as sulphide, associated with copper, iron and other metals associated with galena, zinc blende, mispickel and silver sulphide, generally in a gangue of crystallized quartz.

A SAFE AND SIMPLE TEST for cement is to sift 3 or 4 ounces of the cement through a standard test sieve of 100 meshes per linear inch. Reject cement of which 10% by weight is retained on the sieve. Many Portland cements are on the market which will leave less than 5%. A standard barrel of cement contains 3.65 cubic feet. The average weight of a cubic foot of Portland packed cement is 110 pounds.

THE public mineral lands of the United States, both surveyed and unsurveyed, are open to location by citizens of the United States and those who have declared their intention to become citizens, subject to such regulations as may be prescribed by law and subject also to the rules, regulations and local customs of the miners in the several mining districts, so far as the same may not conflict with the laws of the United States.

THE assay ton on the grain basis was used long before the introduction of the assay ton based on gram weights. Formerly the assay weights used on the Pacific Coast were grains—ten grains being divided into a thousand parts. As it used to read, "1000=10 grains." Thus a weight of 291.66 grains represented an assay ton; .01 of one grain an ounce Troy. J. S. Phillips describes this in his book, first edition printed about 1869, and was in use long before.

THE use of man engines in mines, though introduced early in Cornish mines, were first put in in the Hartz in Germany in 1833, the deep George adit having made two water wheels and pump rods available for the purpose; they were provided with steps and band holds. The next one was put in in the Duke George William shaft in 1838. The first in England was put in in 1842 at the Tresavean mine; the second in 1845 at the Great United mines at Gwennap.

IN SAND, silica is the fire-resisting element—it has no binding property—so that in a sand where adhesiveness is required alumina must be present; silica alone is very refractory; in the presence of the fluxing elements, iron, lime, magnesia, soda and potash, it readily fuses and forms silicates; these silicates fuse or melt at the following temperatures: Silicate of alumina, at 4350° F.; of magnesia, 3960° F.; of lime, 3810° F.; of iron, 3270° F.; of soda, 1600° F. The more lime or alkali present the more easily the sand is converted into a slag.

BLASTING in shafts by the use of the galvanic battery is now successfully accomplished by employing what are termed "delay fuses." These are fuses which require time—the fraction of a second—to cause an explosion. By this means "cutting bores" may be fired first, the intermediate "sinking holes" next and the "squaring-up" bores last. The great damage to timber often resulting by the simultaneous discharge of the full round of bores is thus avoided to a great extent, and the miners do not have to run the risk incident to "spitting" a large number of bores.

IN order to prevent excessive condensation of steam in pipes, the pipes should be covered with some non-conducting substance. For this purpose several varieties of material are manufactured. They are usually molded in cylindrical form, divided in half, and may be quickly placed on the pipe and secured with metal bands. It is estimated that the amount of condensation to a square foot of exposed steam pipe is equal to about eighteen pounds per hour, with steam at 100 pounds, this varying somewhat with the outside temperature. When the pipe is properly covered this loss is reduced to about four pounds. Steam pipes conducted into mines should always be protected in the manner described.

THE gold minerals number but a half dozen, by far the greater part of the metal produced is from the native. Fully forty minerals contain silver, but the production of the metal is mainly from native silver, from argentite,

proustite, pyrrargyrite and stephanite. There are ten minerals from which mercury is extracted, but the one ore, cinnabar, is accountable for seven-eighths of the world's production. There are about 100 minerals containing copper, but five-sixths of the world's production is produced from native copper ores, from the carbonates (malachite and azurite) from the sulphides, chalcocite, chalcocite and tetrahedrite and the oxide cuprite. Upwards of seventy-five minerals contain lead, 90% of the metal produced is derived from the sulphide, galena, while the carbonate (cerussite) is chiefly accountable for the remainder.

MINERS who have learned their craft in a single district usually have much to learn when going into a different State or district remote from their former home. The rocks may be different, the ores different, the character of the mines very different, and necessarily the methods of working also different. In some districts the most ordinary-looking stone is a valuable ore, yet the same appearing rock in another district may be valueless. As examples of this fact, some of the rich gold rock found in the Randsburg, Cal. district would not be given any attention in northern California. In Calico, Cal., ordinary-looking sandstone, jasper or spotted rhyolite, showing no indication of value to the inexperienced eye, carry payable and occasionally high values in silver chloride. In Lawrence county, South Dakota, chert, such as may be seen commonly in limestone, is in some instances rich in gold, and white friable quartzite is rich in silver. One cannot afford to pass hasty judgment on rocks; their appearances may prove deceptive.

SHOULD a vein of valuable mineral be discovered on railroad land, the first step is to ascertain if the railroad have a patent to the land. If they have, the proper course is to buy it from the railroad company. If they have not patented it, the land is subject to location. If a portion of the vein is on government land and a portion on railroad land, and the land is patented, by posting a notice of discovery at some point on the vein where it appears on the government land the locator is entitled to all that portion of the vein lying without the railroad grant, both on the surface and in depth. When the railroad company or the agricultural claimant obtains a patent to land, the patent guarantees to the holder thereof not only the surface of the land, but also all lying beneath it to the center of the earth, but these rights are bounded by planes drawn vertically downward through the boundary lines, and the locator of a vein on government land outside the railroad or agricultural patent may work all of the vein excepting the portion included within the vertical planes established by the boundaries of the railroad or agricultural land.

A WATER PRESSURE of 500 pounds per square inch is too great for domestic or fire purposes. The only practical and satisfactory manner in which this pressure can be reduced to one suitable for this purpose—say 150 pounds—is by the construction of a large tank at the proper elevation—about 345 to 350 feet above the datum plane—and tap the main line at this place, providing a good sized pipe, about 4 inches under the heavy pressure above it, and placing in a good gate with large wheel, or lever for opening and closing, as the pressure at this point will be about 350 pounds per square inch, and on the disc of a 4-inch gate would aggregate about 4375 pounds. In case of fire, the tank being full, an immediate supply is available, and a man may be sent to open the gate at the pressure tank. The ordinary fire hose will stand 200 pounds pressure and more when new. The distance to which water may be projected from a nozzle depends upon the pressure at the nozzle. Right angled turns in pipe lines should be avoided, as they greatly retard the flow of water and are likely to leak badly. The percentage of friction in pipes varies with the size of the pipe, being proportionally greater in small pipes, and also with the velocity of the stream. A 2-inch hose and inch nozzle are only serviceable for use inside buildings, and would give no satisfaction for general fire protection.

THE laws concerning the appropriation and use of water are not altogether satisfactory nor always as clear as might be wished, but in this regard the laws of California provide as follows: The right to the use of running water flowing in a river or stream, or down a canyon or ravine, may be acquired by appropriation. The appropriation shall be for some useful or beneficial purpose, and when the appropriator or his successor in interest ceases to use it for such purposes the right ceases. The person entitled to the use may change the place of diversion, if others are not injured by such change, and may extend the flume, ditch, pipe or aqueduct by which the diversion is made to places beyond that where the first use was made. As between appropriators, the one first in time is the first in right. The appropriator must post a notice at the point of appropriation and this notice shall state the uses to which it is intended to put the water and place of such use, also the size of the flume, ditch, pipe or aqueduct. Actual work must commence within sixty days from date of location and be continued uninterruptedly until completed. A locator cannot claim a larger amount of water than he actually appropriates from the stream. The owner of a ditch has no right to shut off the water legally flowing into the ditch of another. If he is injured by the appropriation of water by another from the same stream he has recourse in the courts.

The Assayer--His Uses and Abuses.

Written for the MINING AND SCIENTIFIC PRESS by
DAVID ATKINS.

Unless he is honest, the assayer is of no use whatever. His accuracy may be proved, to commence with; his quickness is obvious; but, if he does not bold his results inviolable, neither accuracy nor quickness are worth a cent.

Perhaps every assayer has faced the day when his tailings sample went higher than his ore, and, knowing that the part can not be greater than the whole, has wondered what to do. On the surface of it his position is one that promises little credit either way. He may either lie, and know himself a fool, or tell the truth, and give others that impression. But it is the man who writes down what his balance tells him who is worth his place. It may be that he has erred—assayers are human, after all; but, if he erred, nothing in the world is better than his discovery of it. A good man seldom errs twice in the same direction. There is a possibility that his tools are at fault; that his balance indicates its own sweet will, and a variable will at that; or that he is not allowed to use clean crucibles. Then let him say so. There are unquestionably bad balances—balances that are worn out and balances that were never broken in; and as for using dirty crucibles, the practice is as reprehensible as using unsterilized tools in an operating room. Any apparently foolish result that betrays the unreliability of his tools or methods should be welcomed by the assayer. He is not at a mine, as a rule, merely to do a hard day's work and draw a salary, but to turn out accurate work. There are dumps of good ore, condemned as waste by some hasty assayer, that will stand for long years as a monument to his carelessness. If a man's tools will not do him credit, he should have the pride of any honest craftsman and protest.

But it is to be borne in mind that the assayer, even if he is honest, quick and accurate—the perfect assayer—stands for nothing more than the value of his sample. He does not, and can not, say: "This result shows the value of your ore," but: "This result shows the value of your sample," unless he has done the sampling himself and has some understanding of the art. To blame him for another man's poor sampling is one of his commonest abuses. The art of sampling, as it is understood by more than one foreman, is embodied in the old classic:

He stuck in his thumb and pulled out a plum,
And said: "What a good boy am I!"

But, because the pudding is not all plums, the directors will ask: "Who is that assayer they have up there? Here are his samples averaging \$10 a ton, and the mill returns only showing \$2.50. We must get another assayer. Now, I have a nephew just out of college, etc." Here the assayer is abused for the carelessness of the sampler, and as often as not for the errors of the directors and stockholders themselves, who have a bewildering habit of striking averages without considering what amounts are represented. If the face of a drift give two samples, one showing a value of \$19 per ton and the other of \$1 per ton, the average value of the ore coming from that drift is not necessarily \$10 per ton. There may be only 6 inches of the \$19 ore and 66 inches of the other. It is not the assayer's fault that the ore in reality is only worth \$2.50 per ton.

It should always be remembered that assaying is the last of a series of acts going to determine the value of the ore, and is dependent on each previous act. There are superintendents who prepare elaborate statements showing the weight of ore crushed and its value, who show also the weight and average value of their tailings, who have no scales on the property. They estimate the weight of the ore, and then multiply this guess by the assay value. The weight of their tailings they estimate by subtracting the weight of concentrates saved from their first guess. Then, if Providence does not interfere on behalf of the poor assayer and throw up a coincidence, he stands the blame. If it's to be a guessing game, it might as well be left to the secretary in the city. Other interesting results are obtained by taking a lump of ore from each car and calling it a sample, or by weighing the ore wet, assaying it dry, and then multiplying the weight of wet ore by the assay value of the dry. Because the mill can not do conjuring tricks like this, it is hinted that the assayer is a fool or the millman a thief.

Of course, assayers are underpaid; we all are in these days of unions, when the bricklayer and plasterer are earning \$5 to \$7.50 a day; but the remedy is with themselves—though where assayers are being turned out in thousands, it is a very good man who can force the hand of his employer.

These are the most common abuses of the assayer; but there is yet another, which shows itself in the most fiendish variety, but for purposes of consideration may be classed under a common head: It is that of giving the assayer an incompetent superintendent. This is obviously unjust. The superintendent who on being told by his miners that all his mine needed was a

good gouge to break to, and who replied that he would "send to the city for one immediately," is a dangerous man to have around. It was such a one quite recently who dismissed his assayer because he found out that his plate tailings and his concentrator tailings, when added together, came to more than the value of his ore. He did not consider that the value of his final tailings was included twice in the total which appeared so large, and, moreover, he could not be brought to see it. In this case the superintendent was a wise man from the East who had given up a flourishing grocery business to take a turn at mining. It is from these that the assayer seeks for cover.

Having considered the abuses of the assayer, now let us, from the employer's standpoint, consider his uses. The average mine without him is as dangerously situated as a ship without a compass. There are exceptions, of course; for just as the ship that sails away in sight of land is independent of its compass, so the mine that yields free-milling ore may feel its way along by faith and panning.

Primarily, the assayer is at a mine to do the assaying, and to do it accurately and quickly; but his functions need not stop here. If there are means of weighing the ore, let him prepare a monthly chart, showing the disposition of the values, though it should be remarked that such a chart must not be expected to tally to a cent. As St. Peter protested, when St. Paul threw double nines from his dice box: "No miracles between friends!" With ordinary methods of cleaning up, where it is not economy to recover all your gold, since some is absorbed by the plates, and some retained in the batteries and even in the quicksilver, it is vain to expect anything more than an approximation. This chart should show the number of tons of ore crushed and the average value, the number of tons and the value of the concentrates saved and the value of the tailings. It may be asked: "What are his uses, if he can not tell us whether we have all the bullion which belongs to us at the end of the month's run?" These are his uses: To pass upon new ground, as the inspectors pass upon immigrants; to watch the pickpocket tailings like a detective, and when he catches this thief in the act to find out how it happened; be should strip and sift and identify and mark the characteristics; be able to tell you whether your thief is slimy, coarse or greasy; whether the loot is concentrates, gold or amalgam. These are uses enough.

Let your assayer, then, where it is practicable, have overcharge of the mill. A superintendent is none the less in charge who intelligently delegates his authority. Indeed, the successful manager is the man who can free his mind from routine duties to attend to larger questions. Many a man instead of directing is being driven; overburdened with detail, he does the "next thing," whether it is best or not he has no time to ask. And while this delegation of authority frees the manager, it also stimulates the subordinate in no small measure, for there is no spur to effort like responsibility. The assayer, then, should be encouraged to voice his opinion of the milling—not necessarily to the millman, who has as a rule too many masters, but to the superintendent, from whom it is better that all interference should come.

In a going concern, where the ore is fairly stable in value, it may be economy to let the mill samples accumulate for two or three days; for, if one is getting at average values, one obtains the same result from a three-day sample as from three daily samples assayed separately and averaged, and obtains it at less cost, while the labor and money saved might be spent to better advantage in prospecting the mine.

Since, as has been said, the assayer is responsible only for the value of his sample, he should have charge of the sampling in the mine, under the direction of the superintendent or foreman, and would be responsible from start to finish.

If possible, give your assayer time and a trifle of latitude for experimenting. A man who is kept down with litharge, soda and honeash and what flour he can get from the cook, is apt to become a rule-of-thumb man and lose his faculties through disuse.

Copper Output and Prices.

Following is a table of copper output in the United States from 1887 to 1902, inclusive:

	Tons.		Tons.
1902.....	293,830	1894.....	158,120
1901.....	266,716	1893.....	147,033
1900.....	270,588	1892.....	154,018
1899.....	261,313	1891.....	126,839
1898.....	235,050	1890.....	115,966
1897.....	219,481	1889.....	101,239
1896.....	202,235	1888.....	101,054
1895.....	170,137	1887.....	81,017

Following are the highest and lowest prices (in cents per pound) reached by Lake Superior copper in each year of the same period:

1902.....	13.00	1894.....	10.10
1901.....	17.00	1893.....	12.20
1900.....	17.00	1892.....	12.25
1899.....	19.25	1891.....	15.00
1898.....	13.12½	1890.....	17.05
1897.....	12.00	1889.....	17.50
1896.....	12.00	1888.....	17.60
1895.....	12.30	1887.....	17.75

Why Some Mines Employ Incompetent Miners.

Written for the MINING AND SCIENTIFIC PRESS by CHAS. L. LANG.

The poet has declared that "civilized man cannot live without cooks." It is no less true that mines cannot be worked without miners, and it is sometimes not so easy to get them if the mine is unfortunately situated at great distance from the main mining centers.

Much happier is the superintendent or foreman whose operations are conducted in close proximity to the large mining towns, where good accommodations, excellent food at moderate prices, including all the pleasures and allurements dear to the heart of the careless, free and generous toilers from under the surface, make these places a natural magnet, holding within its attraction a continual surplus of first-class men from whom to pick and choose.

But very often nature places a mine in some isolated, forsaken spot, many days removed from even a postoffice, reached only by a long stage or buckboard ride, and often nothing but a tortuous, zigzag trail up rugged summits and down dark canyons, until the dump of tunnel or shaft is seen, bidden amongst the brush and timber, or perhaps standing out against some barren, rocky ridge, wind-swept in winter, or baked by summer suns.

Not much amusement or excitement in a place like this; no wonder that there is dissatisfaction. A dirty bunkhouse, usually alive with bedbugs or worse, three rows of bunks, one over the other like those in the steerage of a ship, is something of a contrast to the hard-finished room with clean bed, mirror and washstand, chairs and carpet, the commonest "mucker" can command in any mining town. At the boarding house there is the usual mixture of chickory and ground peanuts for coffee, bread half baked or else burned and sour, leathery pie crust made of rancid lard and filled with prunes; cake made without eggs, bull butter good and strong, and condensed milk blue and weak; pasty wheat mush, a vile imitation of nutritious oats, with the inevitable sodden hot cakes that require a specially prepared gastric juice to digest. All these things have a tendency to make the miner, accustomed to better things, long for the "flesh pots of Egypt," so to speak, and the first pay day, if he has the endurance to wait that long, sees him wending his way to the settlements, or to some neighboring mine whose reputation for "setting up good grub" is an inducement to change not to be resisted, although its drifts and stopes may be wet, the foreman a "devil's own pusher" and "a crank from way back."

Now, these out-of-the-way mines must be worked as well as mines in or near the towns, but it is a notorious fact that wages alone will not attract good miners to them, as many prefer to lie idle for months rather than accept immediate employment at an "outside" mine.

A crew of poor miners means slow and expensive mining work. It is gradually filtering into the brains of those who own mines in remote and isolated places that men who can command employment by reason of their extra skill are not often compelled to travel in search of work. They will not run the risk of extra hardship, the curtailment of appetites and pleasures, therefore the creature comforts of employees must be considered even if it does entail what may seem unnecessary expense. Acting on this idea the modern superintendent no longer huddles his men together in a bunkhouse; small cabins are built instead, usually 10x12 feet in size, furnished with bedsteads, wire and woolen mattresses. Each cabin is occupied by two men. (Cottages are erected for men with families.) By this arrangement men working on the night shift are not awakened or annoyed, and the day-shift men are not disturbed by the night-shift that comes off of the mine in the early morning.

Reading or club rooms are now built at many mines; these contain a large heating stove, plenty of strong chairs, a long, plain desk, with inkstands and penholders, magazines, mining, sporting and daily papers, card tables, and even a graphophone, the value of which cannot be described in words, for it affords to some extent the relaxation demanded and needed by all who perform heavy and continuous physical labor. This idea is well known to professional athletes; the "Varsity coach" always tries to keep his men in good humor and to select a low comedy man as one of his team, for he knows that the depressing influences exerted on the mind by severe training reacts on the muscles.

Nothing is ever lost by judicious kindness; it is always repaid with heavy interest, no matter what the sour or selfish cynic may say. It is strict business economy to see that your men are well housed, well fed and contented. Improved physical condition means greater capacity for work—and here you have your reward. This principle is carried out in the intelligent handling of animals. Why should they be better used than men?

The writer well knows that "some men would growl though they were to be hanged." But dis-

criminating kindness is not weakness, and a hearty friendliness can be maintained between employer and those who labor without stiff-neckedness on one side or by encouraging the familiarity which is said to breed contempt on the other.

Sonora, Cal., February 7.

Electrolytic Power Plant at Chedde, in the Alps.

Written for the MINING AND SCIENTIFIC PRESS by
FRANK C. PERKINS.

During the past few years there has been a great development of electro-chemical work, both in this country and in Europe. A large number of hydro-electric power plants have been utilized for supply-

The installation at Chedde contains twelve Girard horizontal turbines built by Brenier & Neyret of Grenoble. They each have a capacity of 800 H. P., making a total output of 10,000 H. P., and the total cost of the hydraulic plant was 140 francs per horse power at the turbine shafts. The electrical equipment of this power station consists of four Oerlikon generators, four Belfort machines, and four Thury 8-pole dynamos, the latter having each a capacity of 560 K.W. These machines supply a direct current of 800 amperes at a pressure of 700 volts, the speed being 240 revolutions per minute. These generators may be seen in the foreground of the accompanying illustration (Fig. 1). The electrical equipment of this plant cost 210 francs per horse power and the efficiency of the generators is 95% and that of the turbines 75%. It is stated that the cost of the power per annum at the dynamos is but a trifle over \$4 per

the "white coal" of the Alps for the production of chlorate of potash by the electrolytic process may be mentioned those at St. Michel and Vallorbes, as well as the Usine de Gavet-Clavaux and the Usine de Monthey (Suisse). In this country as well as abroad special electrolytic generators, transformers and other apparatus for use with electric furnaces have been produced by the leading manufacturers. The accompanying illustration (Fig. 2) shows one of the 12-pole direct current machines built by the Cie de L'Industrie Electrique de Geneva, Switzerland, for the Usine de la Praz for the reduction of aluminum. These machines supply 3000 amperes at a pressure of 110 volts, and operate at a speed of 250 revolutions per minute. The plant at La Praz utilizes a total of 8600 H. P. and is operated by the Societe Electro-Metallurgique Francaise. There are also two machines at this plant, each of which supplies 7500 amperes at a potential of 35 volts, the speed being 300 revolutions per minute. Generators of this type are also employed at St. Michel de Maurienne, France.

The Auriferous Zone of Georgia.

Written for the MINING AND SCIENTIFIC PRESS.

The gold-bearing formation in Georgia occupies fully one-third of the area of the State, and, with the exception of about 3500 square miles in the northwest corner, includes the entire State north of a somewhat irregular line from Augusta on the eastern border to Columbus on the western side. This line is the southern boundary of the crystalline area and marks the head of navigation on the rivers, which generally run from north to south. The area here defined may be considered as mica schist, for though there are intrusions of granite and other rocks, the proportion is very small.

The strike of the country rock extends from northeast to southwest, and the veins from which most of the gold has been obtained are parallel with each other in belts which follow the strike of the country rock, and vary in width from 1 to 6 miles. The two great belts are about 25 miles apart and extend from the northeast corner of the State to about the middle of the western boundary line. The belts continue into North Carolina and Alabama, and in the eastern part of the State, about 30 miles north of Augusta, a continuation of a South Carolina belt enters and extends southwest about 40 miles.

The veins are separated from each other in the belts by spaces that vary from 30 to 40 feet up to several hundred feet and rarely cut across the country rock, but are between the planes of the schist and follow its dip and strike. Miners who are disposed to be theoretical would probably change their ideas here about fissure veins, for though these veins conform to the planes of the schist and have no walls, they hold their value in depth. Such a mine is now worked here at a depth of 1300 feet.

The small veins are quartz and the large ones are made up of alternate streaks of quartz and mica schist. The latter are often of great width and are of course low in the value of gold per ton. Denudation has proceeded to a great extent, and the veins can easily be traced on the surface or found by digging a few feet. The placers that came from the decomposition of the veins, as also the free-milling ore that could be found in them, have been worked out and the sulphide ores remain for development.

The veins of Georgia have ore shoots and lean places, like veins in other countries, and the average value of the ore shoots is probably from \$5 to \$7 per ton in gold, which is about the only metal saved here, though some of the veins have considerable value in copper. Lead and silver are not important values.

The dullness in the gold mining business of Georgia is shown by the low price paid for labor. Good miners, white and black, work here with hammer and drill ten hours a day for \$1.25 and with this support themselves and families. There are opportunities here, either on a large or small scale, for those who have capital and thoroughly understand the mining and milling of gold-bearing ores. It is probable that the sulphur in the gold ores of Georgia will have a value as a by-product which can be used in the manufacture of phosphate fertilizers. At present pyrites are brought from Spain and other countries to Georgia to be used in this industry. Gold-bearing ores can be mined here and the values extracted by any process, except smelting, for one-half to two-thirds of the cost of the same work in the western part of the United States. Mining land in Georgia is also farm land and must be purchased from individuals, all the public lands having been disposed of many years ago. The title is from the State of Georgia as one of the thirteen original sovereign States and there are no extralateral rights.

There is a smelter at Atlanta that is well equipped to reduce ore or concentrates to copper matte, but there are no stamp mills, concentrators or chlorination works for custom work, and a miner must also be a mill man and have the capital to build his own mill. As is usual in mining districts, there are stamp mills idle here which have been built by persons who know but little about gold mining, and, as is the custom with such people, they have put up their mills and then proceeded to look for ore.

Fig. 1.—Power Plant for Electrolytic Production of Potassium Chlorate at Haut, Savoie, Switzerland.

ing the necessary current, and at no place has this source of energy been so extensively utilized as in France and Switzerland. The "white coal" of the Alps is now being employed for this work to a great extent, the melting ice and snows of Mont Blanc and other high peaks furnishing water power, which is well sustained through the dry season.

The river Arve supplies about 10,000 H. P. for the production of carbide and chlorate of potash, the power being generated at the works of Chedde, in the commune Passy, department of Savoie. The power house is located in the valley of Chamonix, near the junction of Sallanches. The water is conducted from the river Arve through a large tunnel 288 meters in length, and then another tunnel of 505 meters, at the end of which there is a direct fall of 39.05 meters to the power house in the Ravin du Chatelard, where four turbines of 1300 H. P. operate generators which supply current for an electric railway in the mountains. The water, after passing from the tail race of this power plant, enters a tunnel 672 meters in length, at the end of which there is another direct fall of 139.05 meters to the power house of MM. Corbin & Co. At this plant the water is carried through two steel pipes 1.4 meter in diameter and 400 meters in length. The wrought iron pipes are 15 millimeters in thickness near the turbines and 5 millimeters in thickness at the beginning. The water is carried a total distance of nearly 1800 meters by canal, and it will be noted is utilized in two different power stations.

Fig. 2.—Type of Generator at La Praz, Switzerland.

horse power. The energy is utilized not only for the electrolytic production of potash, but also of soda, by the Gall-Montlaur-Corbin process. This electro-chemical plant is said to produce 1,500,000 pounds of carbide and 9,000,000 pounds of chlorates per year. The chemical works cover an area of 13,000 square meters, the largest building alone having an area of nearly 8000 square meters. Among the other important power plants using

Treatment of Homestake Ores.*

By C. W. MERRILL, Lead, S. D.

Before entering into the question of the metallurgy of the Homestake ore, I wish to invite your attention to the standards which I shall use in its discussion and which are as follows:

1. The U. S. gold dollar.
2. The U. S. ton of 2000 pounds.
3. \$20 67 per ounce of fine gold.
4. Percentages are by weight and not volume.
5. The sizings are based on the following: Coarse

is that portion of the sample which will remain on a 100-mesh screen, diameter of wire .00433 of an inch, size of opening .00575 of an inch square; middles being the material finer than the opening of the above 100-mesh screen and coarser than the opening of the commercial 200-mesh screen as given below; fines being the material which will pass such a 200-mesh screen, diameter of wire .00216 of an inch, size of opening .00312 of an inch square. A further subdivision of fines is also mentioned, which is based upon the granular condition of one portion and the amorphous condition of the remaining portion of these fines.

We now turn to the nature of ore. The Homestake lower level ore, which comprises the greater part of that now being milled at Lead, may be described as a hornblende garnetiferous schist or slate, which has been crushed and infiltrated with free silica and pyrites, the latter being about 7% or 8% of the ore, and comprising pyrite, pyrrhotite, arsenopyrite and traces only of chalcopyrite.

MILLING.—The ore receives its first crushing in rotary breakers at the hoists, and this product varies in size from that of sea sand up to rock having an extreme dimension of 4 inches. From bins at the hoists at Lead the broken ore is trammed to the three mills, i. e., the Homestake and Golden Star, containing 200 stamps each, and the Amicus (formerly the Highland), in which there are 140 heads, making a total of 540.

From the mill bins the ore passes to the mortar, which is of the now celebrated Homestake narrow pattern, where it is crushed between cast iron shoes and dies, the weight of the stamp when equipped with new iron being 900 pounds, the drop 10½ inches and falling eighty-eight times per minute.

The screen is of the steel needle-slot type, No. 8, and the bottom of the screen opening averages 10 inches above the top of the dies.

The long drop, high discharge and small area of screen opening produce an extremely fine pulp, about 80% passing a 100 mesh screen, and it is to me a most remarkable fact that under these conditions such a high stamp duty is maintained, it being fully four tons per stamp for twenty-four hours.

This duty is only possible because, first, of the very favorable nature of the ore, the slate and pyrite crushing readily and the quartz being an excellent medium of attrition; secondly, a large proportion of water is used, being from eight to ten times the weight of ore crushed, and thirdly, because of the narrow mortar, which is only 12 inches wide at the lip.

This very fine and thin pulp is in the most excellent condition for amalgamating, which process is conducted both inside the mortar and outside, on four full size plates, in series (54 by 144 inches by ½ inch), to each mortar. The first of these is a copper plate and the other three are silver plated copper, the weight of plating being two ounces per square foot, and all silver plating being done at the works. The addition of the three silver plates to each stamp battery by Mr. Grier, general manager, has proven one of the most valuable steps in the treatment of this ore, and has brought about an additional profit amounting to approximately \$250,000 during the year 1902, over and above what would have been realized from amalgamation had the outside plate surface been only that of the one copper plate, and which, by the way, is considered ample in many of the large modern plants of the day. In the judgment of the writer much more attention will ultimately be paid to amalgamation and finer crushing in South Africa, and that instead of obtaining from 55% to 60% there on the plates they will more nearly approach the Homestake yield of 70% to 75% by amalgamation and at the same time reduce the value of their cyanide residues. This is particularly true because in that country their slimes are of proven value sufficient for secondary treatment, while such has as yet not been proven at the Homestake, where the advisability of sliming such a large proportion of the ore has been a debatable point. But more of this will be said later.

In connection with amalgamation it should be said that experiments conducted here indicate very strongly that in the case of the Homestake ore the maximum yield on the plates is obtained when the temperature of the water fed to the battery is below 50° F.

The total cost of milling in the 200-stamp mills at Lead is approximately 40 cents per ton.

CLASSIFICATION.—We now have a pulp containing eight or ten parts of water to one of ore, and much of the latter is infinitesimally fine; so much so that

one gentleman, after watching an attempt to filter the slimes on a large scale, remarked that for an exemplification of the size of a molecule he advised the study of Homestake slimes.

The sizing test of the tailings as they leave the mill is about as follows:

Coarse, or that portion remaining on a 100-mesh screen 22%
Middles, or that portion between 100 and 200-mesh 18%
Fines, or that portion passing a 200-mesh screen 60%

That is, the cross-section of 60% of the particles issuing from the mortar is less than 1/1000 of a square inch in area.

Having outlined the metallurgy up to that point at which the secondary treatment begins, it may not be amiss to point out that when the erection of the cyanide plant had been determined upon, the question of a tailings wheel to elevate the pulp and enable the locating of the plant nearer the mills, being under discussion, it was figured out that to elevate the tailings at a cost of about 2 cents per ton would cost the company approximately \$140,000 on the proportion of the material then blocked out in the mine, which would be available for leaching. In other words, for every cent per ton which could be saved in the secondary treatment of the leachable material, the company would profit ultimately to the extent of \$70,000. It is perhaps superfluous to remark that the tailings were not elevated. Consequently the plant was located on its present site, and the problem of transportation and such classification as would permit the pumping plant to return its former percentage of water to the mills presented themselves. The latter has been met by the installation of the upper cone house, where twelve gravity settling cones, 7 feet in diameter and with 50° sides, throw off about one-half of the water and perhaps one-fifth of the solid matter, which latter is the very finest slime of the following sizing during 1902: Coarse 0, middles 1.76%, fines 98.24%. The slimes are subsequently settled out of this pulp and a part of the water returned to the mills.

From the bottom of the above cones is drawn the thickened pulp containing all of the leachable material and some of the slime. This portion is transported by means of a 12-inch cast iron flanged pipe, on a minimum grade of 2½%, and with as few turns as possible, to the cyanide plant.

The second step in the classification is carried out in the plant proper by means of six more gravity settling cones, the overflow from which, of a like composition to that of the first twelve cones, is conducted to a collecting tank, whence it is drawn for the purpose of sluicing out the leachable material after its treatment has been completed. The average sizing of this second settling cone overflow for 1902 was: Coarse 0, middles 1.38%, fines 98.62%.

The underflow from the second set of gravity settling cones, which is now quite thick, passes to twenty-four sizing, or hydraulic classifying cones, which carry a device for discharging the sand and introducing water, which the writer has patented. By its means the admitting of water does not result in currents of varying velocity, which latter always interfere with uniform separation of slimes from granular material.

These sizing cones complete the classification, which has been a difficult problem because, first, of the extreme fineness of the pulp, and secondly, because the writer was determined to avoid double treatment, which entails a largely increased installation and operating cost, but which is necessary unless a product practically freed from slime may be obtained.

The slime overflow from hydraulic classifiers had the following average sizing for 1902: Coarse 0, middles 1.46%; fines 98.45%. As regards all the slimes referred to, they will practically all pass the 200-mesh screen, the middles being largely wood pulp.

In fact there is little doubt but that the importance of the most perfect classification possible will be recognized shortly as a vital consideration in the cyaniding of wet-crushed ore, and metallurgists will not follow the old German practice of spitkasten and spitlutzen, which are very imperfect machines as compared with a cone classifier or sizer. The writer's judgment is that a scientific classification system, by which all the granular or angular material may go to the leaching vats and all the amorphous portion to the slime plant, will in the future be a feature in designing a plant on which the greatest care and experimentation will be put, and the highest grade of technical skill utilized.

By these three steps in the classification we have separated the pulp into non-leachable slimes, all of which will pass a 200-mesh screen, and a direct leachable product, which although very clean and free from mud, is still of a very fine texture, as the following sizing test, the average for the year 1902, will show:

Coarse remaining on 100-mesh 40.5%
Middles, 100 to 200-mesh 30.8%
Fines passing 200-mesh 28.7%

While you will note the fineness, we find that as the proportion of lower level ore increases we can treat an even finer product, a recent charge containing as high as 40% fines, which maintained our normal leaching rate of 3 to 4 inches per hour throughout the treatment. This is undoubtedly due to the fact

that the fines from the lower level rock contain a greater proportion of angular or granular material and a less proportion of amorphous or hydrated.

TREATMENT.—The leachable pulp, which contains 10% to 12% of pyrite, is now ready to go to the vats, and on the way lime is added in quantities varying from three to five pounds per ton. At first we tried adding this lime in the mill, as is done in Africa, but found that the amalgamation was most seriously affected thereby; not only was the plate completely coated, weeks being required to get it back in proper shape, but the tailings values were largely augmented. This result only emphasizes the fact that the process must fit the ore, and that attempts to make an ore fit a process are useless. This practice of adding lime to the battery is unanimously pronounced to work the best results in Africa and to reduce the values in the slimes lost from amalgamation to one-half of what they are when no lime is used in the battery. In our case, however, we have demonstrated that the best results follow from crushing the lime wet into a running pulp which joins that from the cones, whereby there is less slacking and less loss of flocculent lime in the vat overflow, i. e., in the water which overflows the vat, the sand having settled out. Not only is it of distinct advantage to have our lime go into the tank in unslacked granules, but recent investigations are proving that the average size of these granules has an important bearing on the subsequent cyanide decomposition. We are not prepared as yet to say what is the very best mesh screen to use on our lime stamp battery, but at present we are using a wire screen, the opening of which is ¼ of an inch square. In this connection it should be said that only the purest lime should be used, the magnesia in the ordinary dolomitic limestone being objectionable for several reasons.

The classified pulp and the lime pulp having commingled, the mixture passes to the distributor, which is of the garden sprinkler, or Butters & Mein type.

Of these distributors there are two, one for each row of vats, hung from a carriage which travels on a track and the step of which rests on the top of the center bottom discharge gate of each vat when the distributor is in operation. There are fourteen sand vats, each 44 feet in diameter, 9 feet deep inside, and holding 610 tons of sand. To fill one of these requires from eleven to eleven and one-half hours, which permits, with our equipment, of about five days contact with solution before it is necessary to recharge the vat. After filling, the drain valve is opened, the top leveled, and the stronger of the two stock solutions, of a strength of 0.14 of 1% KCN, is run on. The contact with this solution, including frequent drainages for the purpose of drawing in air, is maintained for about three days. The air contact is very important in Homestake ores, owing to the presence of pyrrhotite or sub-sulphide of iron, which absorbs oxygen with great avidity and which would greatly retard the dissolving action of the cyanide solution, were not quantities of this essential oxygen introduced. The effluent solution, during this period, having normally a strength of 0.10 of 1% of cyanide, is run to the weak precipitation tanks, of which there are two, each 26 feet in diameter by 19 feet deep, and holding 300 tons of solution.

After the three-days contact with strong solution, the weak solution, normally of a strength of 0.10% KCN, is brought into the charge and this contact is maintained for the remaining two days. The effluent solution from the charge during this period is run to the strong precipitation or rather collecting tanks, which are of the same size and number as the weak precipitation tanks.

After contact with the weak solution has been completed wash water is brought into the charge, and the washing continued until the effluent solution is down to 0.03 or 0.02 of 1% in KCN and from 5 to 7 cents per ton in value. The charge is now ready for sluicing, which operation is accomplished by two men with 3-inch hose, in about four hours, using the slime water from the overflow of the second settling cone. The four side gates and one center gate afford ample facilities for the discharging. The last inch or so of the sand is sluiced with clear water under seventy-five pounds pressure through 1½-inch hose, and the eight-ounce duck filter, under which is another of cocoa matting, is washed clean. The vat is then filled with water and is ready for the next charging.

PRECIPITATION.—As stated above, the effluent solution resulting from the leaching with strong solution is run to the weak precipitation tanks, and has a value of approximately \$2 per ton and a strength of 0.10 of 1% KCN. When one of these weak precipitation tanks is full the stream is turned to the other and the former is then ready for precipitation. It contains 300 tons of solution, which is brought into agitation by means of compressed air; and about sixty pounds of zinc powder in the form of an emulsion is sprayed in during the agitation. The pump, which is of the compound, duplex, outside packed plunger type, is then started and the mixture pumped through two large filter presses 36 inches square, of the flush plate and distanco frame pattern, containing twenty-four frames, each 4 inches in depth. The gold, silver and excess of zinc remains in the frame and on the cloth, the barren solution passing through the cloth and on to the weak solution storage tank below, which is the same size as the

*Transactions Black Hills Mining Association.

sand vats, whence it passes again to the sand as weak solution. Its value has been reduced by this operation from \$2 to 5 or 10 cents per ton, being a precipitation of 95% to 97½%. The efficiency of this method of precipitation lies largely in the fact that the cloths of the presses are coated with about ½ inch of powdered zinc and precipitate, so that every particle of solution having to pass through the cloths, gets a molecular contact with the precipitant, which is true of no other precipitation process. The presses are run without opening for a month, at the end of which period the press gauges show only about ten pounds pressure, notwithstanding the fact that they then contain about a ton of precipitate, worth about \$50,000. They are cleaned up by two men in about six hours, including the putting together with new cloths.

It is worth while in passing to suggest that figures covering the labor of cleaning up \$50,000 from zinc boxes or electrolytic precipitation would form an interesting comparison.

We must now return to the effluent solutions resulting from the contact of the tailings with weak solution during the latter part of the leaching, which effluent solutions are run to the strong solution collecting vats, which when filled are strengthened to 0.14 of 1% of KCN and pumped directly, without precipitation, to the strong solution storage tank, of the same capacity as the weak storage, whence it goes on to the early treatment of the charge as before mentioned. Its value is from 30 to 50 cents per ton. It will thus be seen that the strong solution of one day becomes the weak solution of the next day and that the values are all accumulated in the weak precipitation tanks. The strong solution thus has an approximately constant value; that is to say, only one-half of the total effluent solution is precipitated, the other half being kept at a constant low value.

REFINING PRECIPITATE.—As the refining of cyanide precipitates is of some importance owing to the well recognized losses which take place in the ordinary methods, which losses are from 2% to 6%, a description of the process we use at the Homestake, in which the loss is less than 0.1 of 1%, may be of interest. The precipitate after removal from the presses is treated first with dilute hydrochloric acid in a lead lined mixing tank equipped with a mechanical agitator, a hood and a powerful exhaust fan. After agitation and settling, the supernatant liquid is forced through a filter press by air pressure. Sulphuric acid is then added, agitation begun and the mixture heated. It is then settled and the supernatant solution put through the press as in the case of the hydrochloric acid. Wash water is then added to the mixing tank and the whole mixture put into the press where it is further washed. The resultant acid-treated precipitate is then removed to a large steam drier where a part of the moisture is expelled, but never all, and the precipitate mixed with litharge, borax, silica and powdered coke. When thoroughly mixed it is sprinkled with a solution of lead acetate and the whole mass briquetted under a pressure of 4000 to 6000 pounds per square inch. The zinc having been removed and the briquettes having been dried, a borax slag develops upon their outer surface upon being charged to the cupel and they fuse quietly, quickly and at a low heat, without dust or volatilization losses. The lead absorbs the values, sinking to the bottom, and the slag is tapped off. All of the slag having been removed, the lead is cupelled off as litharge and the resultant metal, 975 to 985 fine, is ready to run into bars. The cupel slag and the cupel bottom are then put through the blast furnace, the lead content of the slag reduces to lead which absorbs the values and is drawn from the lead well in the usual manner. This lead is returned to the cupel at the next cleanup, the litharge from the cupellation goes to the next precipitate and the blast furnace slag is worth less than \$5 per ton. The total cost of this refining amounts to less than three-quarters of 1%, so the Homestake Co. realizes \$20.52 per ounce for its cyanide gold, less the usual U. S. assay office charges on dore bullion, and the expressage to New York. These charges total between 10 and 11 cents, so that the net realization per ounce of fine gold precipitated is \$20.42 in New York exchange. A parting plant is now contemplated which will make a further saving in this connection and enable the company to turn out fine gold and fine silver.

Having now described the process in detail, let us turn to the question of tonnage, percentage and costs: The maximum monthly tonnage of this plant was attained in October, 1902, when 40,236 tons, or 1298 tons per day, were treated. This gives to the Homestake Co. the largest sand treatment cyanide plant in the world. The next largest being, I believe, that of the Simmer & Jack, in South Africa.

As a comparison of the various assay determinations and valuations which the bullion produces is always of interest, the following figures for the last half of 1902 are given:

Extraction—that is, difference between charge and residue assay multiplied by the tonnage, equals \$292,579.

Precipitation—that is, difference between assays of unprecipitated and precipitated solutions multiplied by the solution tonnage, equals \$301,233.

Gold in precipitate—that is, the assay value of the precipitate sampled upon removal from the presses, \$302,895.

Gold value of bullion shipped, \$307,635.

Silver value of bullion shipped, \$2874.

The average percentage recovered in bullion by the treatment for the past six months is 74.7%.

This is not as high a percentage by bullion as should be recovered from a porous or oxidized ore, or one in which the values are along cleavage planes.

But in view of the fact that such a high percentage is recovered by amalgamation, that the values are very finely disseminated in the Homestake ore, that the tailings are very low grade, we feel, and all our tests so far have verified our conclusions, that it is the economic percentage, that is, the percentage which yields the maximum net profit.

As to operating costs at the Lead cyanide plant, the following are averages per ton for the year 1902, during which time the average value of the sand treated was \$1.65 per ton:

Classification	\$0.017
Treatment — Cyanide	\$0.152
Labor	0.030
Lime	0.022
Supplies	0.005
Precipitation	0.209
Power	0.026
Water	0.051
A-saying	0.026
Refining	0.013
Miscellaneous	0.008
Total	0.005
	\$0.353

As compared with the above, the lowest costs I have seen authoritatively stated for other plants, are as follows:

City & Suburban, S. A.	\$0.55
Goldenhuis Estate	0.605
Goldenhuis Deep	0.62
Robinson	0.62
Worcester	0.72

These African costs refer, of course, to operations before the late war between England and the South African republics; but they are the only figures available to me, and I do not think they have been reduced materially since.

As regards the slimes, which are not at present being treated, their assay value ranges from 80 cents to \$1.10 per ton. I am not aware that even as low treatment costs as the gross value of this material have as yet been attained anywhere in cyaniding slimes, and yet it is a pleasure to be able to say that Mr. Grier, the general manager of the company, has evolved an entirely novel process which promises an economic solution of their treatment. The principle of his proposed method, when worked out in its practical details, will hold out a good possibility of revolutionizing the metallurgical aspect of cyaniding slimes, and may bring to the company another world's record.

The Superficial Enrichment of Tailings Dumps.

TO THE EDITOR:—As to the matter of surface enrichment, I refer to tailings dumps following cyanide treatment; although inclined to think that this would take place in any dump employing a chemical process, as, for instance, in the case of chlorination, bromocyanidation, or in the use of the hyposulphite of soda leaching process, since the values in all these cases exist in practically the same condition, so far as solubilities are concerned.

The matter is not a theoretical one entirely. It was first called to my attention some six years ago, while engaged in operating a tailings plant in Idaho. I discovered, mainly by accident, that tailings, the value of which I knew to be less than \$1.20 per ton, assayed from grab samples, taken from the surface of the dump at various localities, gave values not far from \$4 per ton (these figures are taken from memory, but may be taken as substantially correct). This state of affairs set me to thinking, but before I had an opportunity to investigate the matter I was called away to attend to other matters, and the affair was temporarily dropped. It might be well to add that the assay values of the tailings and the bullion shipments checked reasonably close.

Since that time, on several different occasions, have I noticed a discrepancy of this sort, but only within the past two years has an opportunity occurred to personally investigate the matter.

The results obtained, briefly stated, are as follows: I found samples taken from the surface of several cyanide dumps to carry values, in nearly every instance, in excess of the regular mill tails. I again take the precaution to state that the mill samples, in every case, checked the bullion and solution assays reasonably close, taking monthly averages.

An instance of enrichment occurred recently with which the writer was, in a general way, interested. It was in the case of the Mercur tailings which gave results so high, from superficial sampling, that the assayer became greatly alarmed, until the above solution of the problem was suggested.

In all these cases, and the writer refers only to those cases in which he personally took the samples, it was found that samples taken from about 2 feet beneath the surface gave normal results.

There seems to be little doubt, though I have never tested it, that these high values would cease at a much less distance from the surface than 2 feet,

from the very nature of the proposition, which in low grade tailings would not allow of extensive enrichment.

Very recently an engineer sampled the tailings dump of the Chairman mill, obtaining values far in excess of the actual value of the ore as brought to the mill from the mine. I believe that he took his samples from the surface of the dump, taking a sufficient number of samples to insure accuracy.

Of course the idea is, in a way, a theoretical one, but it is a theory which admits of no other explanation, so far as the writer has been able to determine.

WINTHROP H. WICKHAM.

Denver, Colo., Feb. 25.

Refining Gold by Electrolysis.

Practically all the gold produced by the mines of the world contains more or less silver, some of it a relatively large amount. Silver bullion containing a considerable amount of gold offers no unusual problem in metallurgy, but gold containing small amounts of silver and other impurities in its refining often costs more than the value of the substances separated from the gold.

The problem of refining gold bullion of this character has been solved by electrolysis and this method is now almost exclusively in use in the refineries of the country. As a result only the refined gold is now shipped to the mints and the consequent scarcity of silver has proven an inconvenience in the refining of gold containing small amounts of silver and other substances. By the acid method the gold bullion is alloyed with two and one-third times its weight of silver, and this after granulation is boiled in nitric or sulphuric acid. As a result of the small amount of silver sent to the mints, the same silver has to be employed over and over in the process, causing an unusual expense for acid. If the silver arrived at the mint in about the necessary proportion to the gold—that is two and one-third times as many ounces of silver as ounces of gold—the refining process would be less expensive.

The electrolytic process as practiced at the United States mint at Philadelphia, Pa., is described by D. K. Tuttle, melter and refiner at that institution, in *Electro-chemical Industry*, as follows:

The only process for directly refining gold electrolytically that is known to have been reduced to practice is that patented by Dr. Emil Wohlwill, Hamburg, Germany.

The feature protected by patent is the electrolyte. This is composed of gold chloride solution rather strongly impregnated with free hydrochloric acid, and it is in this latter point that the significance of the invention lies. If a gold anode be placed in a neutral or only slightly acid solution of gold chloride, opposed by a suitable cathode, gold will be deposited by an electric current, but little or no gold will be dissolved from the anode. Free chlorine is given off; a result not to have been anticipated since chlorine is an active solvent for gold. Upon the addition of free hydrochloric acid to the bath, a point is reached where the chlorine at the anode is suppressed and gold passes into solution, equivalent for equivalent, to that deposited. The strength of the electrolyte is easily maintained by such additions of gold chloride from time to time as will be equivalent to the copper, platinum, etc., dissolved from the anode and not deposited on the cathode. The operation is continuous until the solution becomes highly charged with impurities.

In the operation of the process the apparatus consists of first: A dynamo, which, when run at its normal capacity, requires 5 H. P. and furnishes a current of 600 amperes at six volts. The machine having been designed with a view to experimental work, a rheostat in the field winding enables us to regulate the current between 100 and 600 amperes.

Second: The cells, which are of white porcelain, are 15 inches long by 11 inches wide and 8 inches deep. These are filled with a prepared solution of gold tri-chloride containing 30 grammes of gold per litre (3½ Troy ounces per gallon), the depth of the solution being such as not to entirely submerge the anodes. In each of these cells are suspended twelve anodes and thirteen cathodes, in multiple. The anodes are 6 inches in length, 3 inches wide and ½ inch thick. The corresponding cathodes are of fine gold and rolled down to ⅓ of an inch in thickness. The distance between anode and cathode is 1½ inches. In our present working seven cells are placed end to end on a bed of sand, underlying which is a series of steam pipes by which the temperature of the bath may be raised and maintained at any desired degree. At present our cells are kept at from 50° to 55° C. The increased temperature serves to reduce the voltage required, and at the same time to diminish the amount of free acid necessary to suppress evolution of chlorine at the anodes.

Circulation of the electrolyte by mechanical means is necessary to secure uniform disintegration of the anode and deposition of the gold.

The seven cells in use are connected up, in series, with the dynamo, which is at present regulated to furnish 100 amperes. The tension between the terminals of the seven cells varies from four and a half

to five volts, dependent upon temperature, strength of solution, etc.

The chemical equivalent of gold is very high and the electromotive force required for the deposition of gold is very low, so that the power necessary for running the plant is insignificant. With only seven cells of our plant in operation, we are refining about 5000 ounces per week, with the expenditure of about 1 H. P. One attendant suffices to manage the work, with the occasional assistance of a second workman.

The cost of hydrochloric acid in the bath is 20 cents per 1000 ounces of deposited gold. We can increase our refining capacity to 50,000 ounces per week with our present plant.

Besides the advantage the process offers for the refining of gold with an insignificant consumption of acid, with little labor and small expenditure of power, an important one should be mentioned, viz., the recovery of any platinum present in the bullion. This dissolves, but is not deposited with the gold. When the electrolyte becomes sufficiently charged with platinum, the gold is first precipitated by sulphur dioxide and removed. Then the platinum remaining in solution is separated as ammonium platinum chloride. Lastly, the copper is recovered by passing the wash waters over iron scrap.

With these advantages to its credit, the process has limitations which are serious ones. Any silver in the anodes will, of course, be converted into insoluble chloride, and if the percentage be small will fall to the bottom of the containing tank as "slimes." But if the amount of silver exceed 5% the chloride tends to adhere to the anode, as a crust, which must be mechanically removed.

Furthermore, any considerable quantity of copper present in the bullion to be treated is undesirable, since the electrolyte, in that case, must be renewed inconveniently often.

There seems to be reason to think that any electrolytic process for parting and refining gold will not have the same success in this country in our industrial plants as it met in Europe. The Australian, South African and Hong Kong native gold is very much purer than even our California nuggets and they were very much better than our recent finds in Alaska.

Hong Kong gold is reported as containing .975 gold, .020 silver, .0005 platinum, .0005 iridium.

Some recent consignments of Klondike gold to this mint varied from .776 gold to .834 gold, .219 silver to .161 silver, with no showing of platinum or iridium in the electrolyte.

Such bullion can only be successfully treated by the "Wohlwill" process when blended with a higher-grade gold. We prefer not to treat bullion having a fineness of less than .940 gold.

Again, the Government conditions for the gold producer here are much more favorable than in other countries. At any United States mint or assay office the depositor is entitled to receive promptly upon assay of his bullion all the gold it contains in the form of gold coin or draft on the treasury, less some slight charges. If the amount of the deposit be large he may even receive an advance of 80% on its approximate value at the time of making the deposit. Under these circumstances the question of interest becomes an important item with the industrial establishments. With a given output per diem, several times the value will be locked up in solutions, anodes, cathodes and material in various stages of leaching, melting, etc.

Cananea Copper Mines.

TO THE EDITOR:—Now that W. C. Greene has disposed of his interests in the Cananea mines, some who are familiar with these famous producers of copper are wondering how the purchasers of them are going to profit by their investment. For some time the management of the Cananea mines has been contemplating and has partly attempted the most rigid economy. They have earned for themselves the reputation of being antagonistic toward laborers of all descriptions, and are in consequence suffering from the loss of the good will of their employees. In the West this is a serious matter to consider; in Cananea it is especially so.

When it is known that all the expensive construction work of the Cananea company has been completed the attempts at economy through the reduction of salaries and wages of American employees are looked at with distrust. It might indeed be wiser to abolish the system of employing Americans at American wages and employ Mexicans only in every department. That the company will ultimately substitute Mexican for American labor seems likely.

Appreciating the superiority of American labor the Cananea company is trying to secure it cheaply. Miners and mechanics from the United States are paid at the rate of from \$3.50 to \$8 gold per day, while Mexicans for similar employments receive from \$3 to \$5, Mexican money, per day. To abolish the difference the company assesses the American employees \$2.50 gold for hospital fees and \$2.50 gold for rent, and sometimes discharges them from employment after a service of from five to eight days. This would reduce the net earnings of the Americans to from \$1 to \$2 per day gold. The labor difficulty is the principal one in the way of the Cananea company. The epoch of favoritism is passed. No longer is

there seen in Cananea a boss to a man and a boss in a man's way. But this is only a small advance. If American labor in the great camp is to be supplanted by Mexican labor the bosses must be able to speak Spanish fluently. Usually the most competent mining and smelting officials are not versed in Spanish. At the same time that the Cananea mines must be worked by the cheapest kind of Mexican labor they must be supervised by expert mining men, and at the present time these two desiderata do not seem to be achieved.

The conditions of the mines themselves show why these things are necessary. According to R. Mitchell, general manager of the smelter, the productive capacity of the reduction plant of the company is 65,000,000 pounds of copper per year. Allowing that this is true, although it seems exaggerated, the value of the output of the Cananea company is about \$8,000,000 annually laid down at New York.

While W. C. Greene states that the company can produce copper at a profit of $\frac{1}{2}$ cents per pound the actual working test shows that ore carrying $\frac{1}{2}$ % copper can be worked barely at a profit.

The mines producing ore are the Elisa, the Capote

Tramming by Gravity.

Written for the MINING AND SCIENTIFIC PRESS

As mining regions are usually in a mountainous, or, at least, a hilly country, the problem of transportation is often a serious one from the standpoint of economy. The ideal condition or surroundings do not often obtain. A vein is usually discovered on the slopes or the summit of a hill or mountain, for the reason that the vein, if existing near the base of the slope, is often covered by the talus formed by the debris coming from higher points on the hillside. As the discovery is made at some high point, so the early development of the mine is likely to be done at or near the place of discovery. Mills or other works for the treatment of the ore are generally built at some lower point on the slope or in the gulch below. Often, to convey the ore from the mouth of the tunnel driven into the mountain, or shaft sunk on the vein, an expensive road is built from mine to mill or shipping station, and on it the ore is packed on animals or hauled in wagons. In other instances the

Fig. 1.—Side Elevation of Gravity Tramway.

Fig. 2.—Plan of Double-Track Gravity Tramway.

and the Oversight. The Veta Grande and Cohre Grande are hut small producers comparatively. The Elisa yields 175 tons of ore per day of an average of 8% copper per ton, the Capote yields 725 tons of 6% ore, and the Oversight 300 tons of 10%. So difficult is the ore to treat, owing to the amount of siliceous matter in it, that it is necessary to use 300 tons of flux per day. This flux is barren of metal. Taking all in all the material treated by the Cananea smelter yields copper to the extent of 5.8% of the gross bulk. About 87 tons of copper is produced daily from 1500 tons of earth.

By shutting the Capote mine down and devoting every energy toward extracting the high-grade ores of the Oversight and Elisa, by good management 300 tons of 8% ore can be taken from the Elisa daily after extending workings in the mine for a period of six months. From the Oversight a production of 700 tons of 10% ore could be brought about in six months. But so great are the siliceous contents of the Oversight ores and the solfataric features of the Elisa ores, at least 500 tons of flux would be required in their treatment. At any rate, however, the results would be very advantageous to the company. In the contingency of both an increase in the copper percentage and an advance in the price of copper the company would be put on a very safe dividend paying basis.

But Mr. Greene has stepped out of the Cananea company's problem by turning it over to Rockefeller. Naco, Ariz., Feb. 28.

ore is shot down a long chute of lumber or through a good-sized pipe. When the tonnage to be handled is large and the country rough, aerial ropeways are superior to other means for transportation; but under ordinary conditions a grade may be made on a line joining the two points—mine and mill—on which a track may be constructed, the cars running by gravity, the loaded car going down developing sufficient power to haul the empty one up. The tracks may be built single with turn-out at the center; but this is not advisable, owing to interference of the ropes. The three-rail track is not uncommon and is in use at many places. This is also constructed with a midway turn-out. The most satisfactory track is double, with no turn out, and, consequently, no interference from passing cars, derailling on switches, etc.

Where the grade is heavy, some device must be built at the upper end of the tramway to control the cars, as the loaded car on starting down the incline may so nearly balance the empty car at the foot that it starts gently and moves with little velocity; but, as the loaded car passes downward, the distance between the empty car and the sheave at the head of the tramway grows constantly less, with accordingly less weight of rope, while the loaded car has an increasingly greater amount of rope and weight, and the speed is accordingly greatly accelerated.

Ordinarily the tramway rope is wound on reels similar to those in use on ordinary hoisting engines.

The accompanying sketches illustrate an ingenious method of constructing the upper station for double-

track tramway, whether built on the ground or on trestle. Fig. 1 shows a side elevation of the construction and Fig. 2 the plan of same. A and C are sheave wheels, running loose on the shaft but secured by collars at the side to prevent possible travel. B B are brake surfaces forming a portion of the sheave wheels. D is a third wheel disposed midway between A and C, but placed horizontally, as shown at D in Fig. 1. L is a lever connecting with the brake hands which operate on B B. The brake construction is also shown in Fig. 1. The rope attached to the car running on the track opposite A passes over A, half way around D and under C, and thence is attached to the second car. The sheaves and shafts are disposed and constructed as shown in the drawings. The frame should be solidly built and securely anchored. The cost of such head rigging on a tramway of this description is much less than where cylindrical reels are used.

A novelty in the operation of a gravity tram is in use at a slate quarry near Placerville, El Dorado county, Cal. The slate is quarried on the slope of a steep mountain side and is elevated several hundred feet on a gravity road to near the top of the hill, where the wagons are loaded. At this place the loaded car has to be hauled up. To accomplish this, on the track opposite the slate car, or "giraffe," is a four-wheeled truck, upon which is secured an iron barrel supplied with a valve at the lower end, operated by a projecting spindle, similar to valve hockets used in some mines. The quarry company own a ditch near the top of the tramway and from this fill the iron barrel with water. The weight of the barrel when full is sufficient to pull the "giraffe" loaded with slate to the upper station, where it is secured by brake until the load is removed. In the case of ore this might be accomplished automatically by dumping; but slate can not be handled in this manner. Upon the arrival of the water barrel at the foot of the incline, the spindle at the bottom of the barrel meets an obstruction which causes the valve to raise, the water escaping. The "giraffe," being heavier than the truck with its empty water barrel, upon being released, descends, hauling up the latter.

No practical use can be made of this ingenious scheme in sending ore down a gravity road.

The Congress Mine, Congress, Arizona.*

The illustration on page 145 gives an idea of what is going on at Congress, Arizona.

The Congress Consolidated Mines Co., Ltd., have recently started their new mill of forty stamps, making a total of eighty stamps. The engraving shows

Head Frame Congress Mine, Arizona.

all of their plants except three hoists, which are over the hill back of the mill. There is a tunnel 1200 feet in length running through the mountain and ore from these shafts is sent through the tunnel to the mill, and supplies for the shafts are taken on return trips. The treatment at the mill is wet crushing with stamps, followed by concentration on tables. The tailings are separated into two classes. The coarse sands are treated by the cyanide process and the finer material (slimes) is first roasted in mechanical furnaces and then treated by cyanide. As there is no free gold in the ore, plates are not used and no amalgamation attempted. The mill treats about 300 tons per day. Their water supply is obtained from Date creek and is pumped a distance of 8 miles and

raised 500 feet. They use about 100,000 gallons of water per day.

The deepest workings are now 3500 feet on the dip of the vein, which is about 22°. This is known as the Congress vein. They have two other veins approximately parallel, one of which is known as the Niagara. On this they have two shafts 3300 feet apart, one of which is down 1000 feet and the other 1300 feet, showing strong veins of normal grade at that depth.

The machinery used in and around the mine and mill is up-to-date and includes an air compressing plant. Machine drills are used in the mine—twenty-five in all. They own the railroad from the mine to the main line of the Santa Fe, Prescott & Phoenix Railway.

The company have completed a brick store and office building, which makes a great improvement to the town.

The ore is white quartz carrying iron pyrites. The average value of the ore is stated to be \$15 per ton. There is reported to be more "ore in sight" than ever before. There are 450 men employed at this property.

Under ordinary conditions, head frames at mines are not only located at the collar of the shaft of the mine, but usually at no great distance from the hoisting engines. Owing to the unusual conditions at No. 6 shaft of the Congress mine, the head frame herewith illustrated was particularly designed by the company's engineer. Manager W. F. Stanton describes the innovation in head gear and placing of power as follows: The shaft is 1300 feet deep, at an inclination of 45° to over 50°. The self-dumping skip is of one-ton capacity and travels in the shaft 1000 feet per minute. The engine is 900 feet distant from the shaft and 98 feet higher than the collar, and the line of rope leading from the engine makes an angle of 80° with the center of the shaft. The rope from the skip leads over the top sheave in the head frame, then straight downward to a sheave at the base of the frame, and thence over guide sheaves and rollers to the engine. Another peculiar and equally unusual construction of head frame is that at the Argonaut mine, Jackson, Amador county, Cal. At this mine the head frame in general appearance resembles that at the No. 6 shaft of the Congress mine. The shaft is inclined at 63° from the horizon. The "angle braces" are usually found on the side next the hoisting engine, and are designed to take the thrust, or resultant strain, the direction of which is about midway between the center of the shaft and the hoisting reel. In the case of the Argonaut frame, the "braces" are at the back of the structure, opposite to the engine, and to the casual observer serve no useful purpose. The

engine is nearly 200 feet distant from the head sheave and about 60 feet lower on the sloping hillside. The entire head frame is constructed on a level grade cut into the hillside, and the "braces" are heavily bolted to mudsills, the whole being weighed down with about thirty tons of old iron, rocks, etc. When this is understood, the construction of the frame is appreciated, though, at first glance, contrary to all recognized ideas of engineering.

THERE is no competition among the miners of gold. There is no dread of overproduction, no fear of a fall in price. Miners of base metals have all of the annoyance and mischance that besets the gold miner, and the additional cares of competition and variable market.

Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 24, 1903.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MOUNTAIN ROPE LIFT.—No. 720,909; W. Feldmann, Elberfeld, Germany.

A rope lift or elevator provided with double or duplex supporting cable located in plane passing through center of gravity of supported car, each part of cable being adapted to independently support car and both parts thereof permanently secured at upper station and yieldingly connected together at lower station and to counterweight or mass in such manner that they are always maintained under constant tension.

DISCHARGE VALVE FOR COMPRESSORS.—No. 721,221; B. V. Nordberg, Milwaukee, Wis.

In pump or compressor combination with cylindrical valve chamber communicating with pump cylinder through discharge port thereof and having outlet port, of oscillatory discharge valve having cylindrical hearings at ends fitted in chamber, and longitudinal working face spanning cylinder exhaust port when valve is closed, valve being cut away outside its working face between its end hearings to leave clear space between it and inner wall of valve chamber, and formed with one or more transverse passages leading from its working face opening on both sides of valve into space, an outwardly opening cup-shaped valve seated in each of passages, cap or plug closing outer end of each of passages, and spring interposed between each relief valve and associated cap or plug.

BAND FASTENER FOR TANKS.—No. 721,539; P. H. Bruinekool, Pella, Iowa.

An improved hand fastener for tanks, comprising in combination two independent frames, each having substantially flat base, upright sides having openings

*See illustration on front page.

therein to receive journal, and integral cross piece connecting sides arranged slight distance above base and having opening through its central portion parallel with base, pivoted pawl having journals passed through openings in side pieces and having a central recess substantially in line with the opening in cross piece, and having eccentric, toothed, lower end, and bolt passed through cross pieces of two lugs, through recesses in pawls, and nuts on end of bolt resting against outer faces of cross pieces.

BLAST FURNACE.—No. 721,417; R. Berg, Pittsburgh, Pa.

In blast furnace combination, with bush shell at lower part of furnace provided with openings, of horizontal ribs at interior of shell, firebrick lining supported between ribs and provided with channels, main pipe encircling lower part of furnace and connected with source of compressed and cooled air, and valved branch pipes connecting main pipes with openings in bosh shell so as to supply compressed and cooled air to same and to interior of furnace.

BLASTING CARTRIDGE.—No. 721,432; T. F. Durham, Philadelphia, Pa.

In safety blasting cartridge of character described, outer tube formed with one end closed, closed end being conical or tapering, other end being interiorly threaded, screw plug adapted to be inserted in threaded end, inner tube formed with one closed end, other end being interiorly threaded, screw plug threaded in threaded end, longitudinal ribs formed with interior tube, inner and outer tubes being molded from material composed of mixture of cement and silica, both screw plugs being provided with central openings from exterior of outer tube to interior of inner tube.

ELECTRO-MAGNET FOR SEPARATING METALS.—No. 721,490; G. H. Young, Elmira, N. Y.

An electro-magnetic separator for hand manipulation.

tion comprising steel or iron core of U shape having spool of wire wound upon each leg thereof, wire in spools running from one spool to other and ends being carried through suitable cable to source of current supply, bend of core piece forming handle, and button or other switch located in proximity to handle whereby current may be switched on or off by hand which grasps instrument.

APPARATUS FOR FORMING BLAST FURNACE CHARGES.—No. 721,505; A. S. Dwight, New York, N. Y.

An apparatus for forming blast furnace charges, comprising hopper, cone upon apex end of which hopper discharges, cartridge boxes into which base of cone discharges, and connected conveyers each receiving contents of one of boxes and delivering contents to common place discharge, and means for receiving and conveying charges one at time from common place of discharge.

APPARATUS FOR RECEIVING AND HANDLING MOLTEN MATERIALS.—No. 721,288; P. Danckwardt, Deadwood, S. D.

Apparatus for handling molten materials, composed of wheel-mounted pot having flat bottom and inclined straight front, false bottom, false front, and means for removably securing false bottom and false front to pot.

CRUSHING ROLL.—No. 721,208; W. C. Madge, Anaconda, Mont.

In crushing roll, combination of core provided with continuous peripheral groove and with circular series transverse mortises crossing groove counter-bored at both faces of core, series shoes engaging periphery of core and provided with mortised flanges engaging groove of core, tapering keys extending through mortises of core and shoes, and nuts upon smaller ends of keys.

ORE CONCENTRATOR.—No. 721,591; J. H. Michelsen and M. La Mothe Borglum, Butte, Mont.

In ore concentrator, combination of table, means for reciprocating table longitudinally, framework of machine, lever pivoted thereon, means for securing lever in different positions upon framework, and link or arm pivoted to table, link and lever being pivoted together in horizontal plane.

METHOD OF PURIFYING BLAST FURNACE GASES.—No. 721,617; G. J. Snelus, Frizington, England.

Method of treating blast furnace gas, consisting in passing gas through mixture of hot fuel, small bituminous coal and suitable flux, extracting dust from gas by forming with dust and flux fusible slag, enriching furnace gas by admixture therewith of gaseous products from bituminous coal, and converting carbon dioxide contained in furnace gas into carbon monoxide by combustion of carbonaceous fuel.

The Armstrong Universal Ratchet.

The Armstrong Bros. Tool Co. of Chicago, Ill., have recently placed on the market their Universal ratchet, a machine which they describe as having a great deal of merit and one capable of doing great service in tight places, being especially adapted to drilling holes in cramped places, which fact ought to make the ratchet serviceable in and about mines. It will drive a drill in any position where it is possible

Armstrong Universal Ratchet.

to move the handle either in vertical or horizontal direction or at any intermediate angle. The machine has no ball joints, bevel gears or other complicated parts, and for ordinary work the handle can be rigidly fixed almost instantly.

The movement is described as a new one. "Even a vertical motion of the handle will drive the drill. The bearings are cylindrical. The pawls do not slide lengthwise on the ratchet teeth. The universal quality of the tool is due only to the fact that the axis of the two trunnions on which the handle turns is at an acute angle with the axis of the drill. About 2 inches of motion of the end of the handle in any direction whatever will drive the drill. Fix the set screw up into one of the three countersinks, and you have a rigid handle, as in the common ratchet. In two of these fixed positions the handle stands at an angle out of the way of possible obstructions. In the No. 6 ratchet there are twelve large teeth in the ratchet and five pawls which engage one at a time. Thus the pawls catch sixty times in a revolution. For this reason the tool cuts about one-seventh faster than the common ratchet, even in ordinary positions, for it takes one stroke of the handle less to make the drill turn once around."

Mining Summary.

Specially compiled and reported for the
MINING AND SCIENTIFIC PRESS.

ALASKA.

J. E. Cooling of Seattle, Wash., and S. Colclough of San Francisco, Cal., report the discovery of stream tin in their claims on Buck and Gold creeks, near Cape York, about 10 miles back from the coast. These creeks are stated to be 40 to 80 feet wide and 8 or 9 feet to bedrock. The prospect was discovered where the streams debouch from the gulches into an open, low, rolling country. No veins have been discovered as yet. The formation is slate.

W. B. Cotter, operating on Harris creek, near Nome, says Harris creek produced some gold the past season and the outlook in the Kougarak region is good. On Dahl creek, on claims owned by Yarnell, Olsen & Galvin, there are 2000 feet of ground stripped and in the face of the drift gold is showing.

Around Shovel creek, in the Solomon river region, near Nome, there are 100 men, with winter camps established. With the development of quartz, along with winter and summer placer diggings, the property holders consider the prospects of the camp encouraging. A good many men are at work taking out dumps for the spring cleanup. On Moran gulch, opposite No. 13 below, on Solomon river, W. Nelson is prospecting with a gasoline thawer. Ross & Chase have a lease on No. 7 below. They have a steam thawer at work. On No. 8, West creek, F. Alden is drifting on a quartz location. At the Lane quartz mine Superintendent Williams has men at work crosscutting and tunneling. The main shaft is down 115 feet. The mill is being installed.

The Nome Gold Digger says Nelson Bros., operating No. 10 on Hastings creek, run in two drifts and at a depth of 12 feet opened up three 2-inch strata of ruby sand, 15 inches apart, with gold in places plainly visible. The layers are removed one at a time, carrying the pay dirt in a canvas cloth to their cabin near the beach and the gold rocked out.

ARIZONA.

COCHISE COUNTY.

The Calumet & Cochise Dev. Co. has been organized by Lake Superior copper men to develop a group of fourteen claims in the Warren district, adjoining the Lake Superior & Pittsburg, Calumet & Pittsburg and Calumet & Bisbee.

The Calumet & Arizona Co. have bought a group of fourteen claims near Don Luis, out from Bisbee, for \$150,000.

GILA COUNTY.

G. Chittenden, manager of the Saddle Mountain M. Co., having an option on four claims in the Reed or lower basin of the San Carlos coal fields, near San Carlos, has begun development work.

M. Hotz, M. J. Murphy and H. J. Sisty, developing the Sultan group and other claims in Lost gulch, near Globe, have leased the Girard mill and expect to start it up next week on ore from the Badger mine.

The A. B. Copper Co., near Globe, under A. E. Wiley, superintendent, are working two shifts and sinking two double-compartment shafts. On the Bird they are down 145 feet and on the Tiptop of the Taylor group they have sunk 45 feet since Feb. 1. A steam hoist will be put up as soon as water is struck. In this district there are six shafts being sunk by five companies—a double-compartment at each the Mallory and Copper Hill, a three-compartment shaft at the Grey, a four-compartment at the O. D., and two double-compartment at the A. B.

GRAHAM COUNTY.

The Detroit Copper Co., near Morenci, are remodeling their plant. The new furnaces are of the copper matte variety. The concentrator will be changed from 500 to 800 tons capacity.

MARICOPA COUNTY.

C. H. Akers, president and manager of the Oro Grande Exploration & Dev. Co., has a bond on the Grand View group in the Blue Tank district, near Wickenburg.

MOHAVE COUNTY.

(Special Correspondence).—The Philadelphia-Arizona M. Co., E. T. Loy, general manager, at Chloride, operating the Minnesota-Connor, has the shaft down 600 feet. The milling ore goes to a bin of 250 tons capacity. The copper ore bin holds 150 tons.

The ore is dumped on a grizzly, the fine drops into the boot. The coarse goes through a Blake crusher on to another grizzly, the fine into a boot, the coarse to

a 11"x15" Dodge breaker, which crushes to 1/2 inch and less. Then the whole drops into a conveyor and is sent to rolls 14"x27", from which it drops into a bin. Thence it is fed to the second rolls, 14"x27", and elevated to a set of three screens which sizes for four jigs. The hydraulic sizers then feeds two Wilfley tables, the overflow going to a 40-foot V tank which sizes and feeds three tables. From the trommels it is fed to jigs. The middlings from the first jig return to the second roll, and middlings from the second and third jigs return to the third rolls. Middlings from the fourth jig and coarse Wilfleys run to a 5-foot Chilian mill. After feeding the middlings to the Chilian mill it goes into a settling tank 38 feet long. From the Chilian mill it feeds into a V tank which sizes for two tables, two Frue vanners handling the slimes. The concentrates from all parts of the mill feed into a hopper on the lower floor where they are drawn off and run to drying bins, whence they are sent to the railroad 1 1/2 miles from the mill.

Water is scarce in this locality and is kept in circulation. In concentrating they lose about 20% of the water. The tailings are discharged into a tank and drawn off into a car and the water drained off. The water is settled in tanks and pumped to a reservoir above the mill, holding 20,000 gallons.

The power used in mine and mill is furnished by an 180 H. P. Corliss engine, three 100 H. P. high-pressure Atlas boilers, a Cochran feeder and separator combined. Oil is used for fuel. All of the oil pipes are under a concrete floor. They have one 50 K. W. generator. The oil storage tank holds 25,000 gallons, with a 15,000-gallon tank at the railroad. The mill, hoist and entire plant can be run with nine barrels of oil per twenty-four hours. In the blacksmith shop the machinery is operated by power. Capacity of the mill is 150 to 200 tons per day. The ore is sulphide bearing gold, silver and copper, 40% of the value being gold. The property consists of sixteen claims. In places the vein is 20 feet wide of milling ore. There is a large amount of ore blocked out, but the company will be obliged to develop more water. Water for domestic and boiler use is obtained 1/2 mile from the mill, the remainder of the water coming from the mine.

Chloride, Feb. 26.

PINAL COUNTY.

At Troy a strike in the Alice mine is reported. In a crosscut, at a depth of 200 feet, 2 feet of black sulphurets assaying \$26 in gold were cut, and at a depth of 400 feet the ore body widened to 4 feet, giving \$20 and 12% copper.

SANTA CRUZ COUNTY.

(Special Correspondence).—The Nogales C. Co. of this place will build a large stamp mill and cyanide plant on the property they recently bought.

L. F. Swain, manager St. Bibiana M. Co. of this place, is about to make extensive purchases of that class of machinery. Nogales, March 1.

(Special Correspondence).—The Nogales C. Co. of Nogales have seventeen claims 12 miles northeast of Nogales. They have 3000 feet of development. They intend erecting a mill. Ore averages 6% copper and two to four ounces in silver. The same company are working a lead property 18 miles west of Nogales. Have a dump of 30,000 tons of 20% lead ore. In the lower workings they have struck ore reported to run 45% to 60% lead and six to ten ounces in silver. There is a hoisting plant on the property.

Nogales, March 2.

(Special Correspondence).—The Pride of the West mine, mill and smelter at Washington are closed down and no definite information can be obtained when they will start up.

Washington, Feb. 28.

YAVAPAI COUNTY.

G. W. Middleton of Prescott is going to put in a smelter.

The Great Belcher-Bullwhacker G. Co. is the name of a merger organized to include the Great Belcher mine and the Bullwhacker mine, near Prescott.

Manager D. C. Monroe of the Monroe Con. M. Co. at Walker says they will install reduction works of 200 tons capacity per day.

N. C. Bonnevile of Denver, Colo., consulting engineer, says they are planning the erection of a 100 ton mill at the Crown Point mine, near Prescott.

L. Pfau, president of the Pfau G. M. & R. Co., says they will start operations on the Verde slope of the Cherry Creek district, 12 miles south of Jerome. Their holdings include the Red Hill group, Valley Anthony, St. Claire and millsite of six acres.

The tailings dump of 30,000 tons at the Crown King mine, near Prescott, is reported sold to New York men for \$75,000,

and that the same parties were given an option on the mine.

YUMA COUNTY.

The Success Copper Co., at Quartzsite, C. E. Eichelberger of Los Angeles, Cal., president, propose to erect a smelter at Yuma, where the ore can be treated at low cost. Additional development machinery is being installed at the mine.

CALIFORNIA.

AMADOR COUNTY.

At the South Eureka mine, near Jackson, crosscuts have been run 300 feet east and west, and to the east ore has been found. The main shaft, down 2300 feet, will be continued 100 feet deeper and other crosscuts run.

The repairs to the shaft and machinery at the Zella mine, at Jackson, have been completed and operations resumed this week.

At the Central Eureka mine, near Sutter Creek, the management is taking advantage of the temporary hang-up of the mill—due to failure of electric power with which it was operated—by starting sinking and will put the shaft down 100 feet deeper.

BUTTE COUNTY.

W. P. Lynch has bought the Spring Valley hydraulic mine at Cherokee, including the Concow reservoir and water right, which is considered sufficient to run the mine by drifting. Operations will resume this week.

CALAVERAS COUNTY.

The machinery for the Carson Hill G. M. Co., near Irvine, is on the ground. The tunnel is in 110 feet, says Manager S. P. Smith.

The Morris tunnel, being driven through Bald mountain, near Sonora, from the Woods creek side, is in 1100 feet.

Work has begun on Nigger hill, near Jamestown, on the group recently bought by J. P. E. Heintz. M. P. Pinney is superintendent and a double-compartment shaft will be sunk.

At the Grizzly mine, near Carters, Superintendent W. R. Hall says drifts north and south have struck ribbon rock. The vein is 5 feet wide and shows free gold. The Grizzly shaft is down 300 feet below the 1700-foot bottom of the Dead Horse.

The Sherman mine, in Salt Spring Valley, near Hodson, is being worked by Superintendent Rathburn, and a 3 stamp mill is crushing ore from one of the veins.

The Easy Bird quartz mine, on the Mokelumne river, north of Mokelumne Hill, is working twenty men. The Peek ditch, taking water from the Mokelumne canal, is being cleaned out, and as soon as this is completed grading for a 10-stamp mill will begin.

T. Rooney of San Francisco has begun work on the Bernardi blue gravel mine, at Chili gulch, near Mokelumne Hill, with ten men, under the superintendency of F. Bernardi.

The Calaveras Chronicle says Superintendent W. T. Robinson has twelve men at work on the Red Hill gravel mine, at Buckeye, near Mokelumne Hill, and 4000 feet of hydraulic pipe is being laid. A tunnel is being run under the ditch to tap the channel from the head of Alexander gulch.

The Nineteenth Century quartz mine and the Pocket placer mine, on French Hill, near Mokelumne Hill, was hounded last week to the Nebraska-California M. Co. for two years for \$2000. The first work will be clearing out the water ditch and putting up a pumping plant.

KERN COUNTY.

The 10-stamp mill building at the Echo mine, 5 miles from Mojave, will be completed by March 10. Development of the mine is in progress.

At Sunset the Gilt Edge has a well down 1600 feet and in oil sand.

At McKittrick, the McKittrick Oil Co. reports having brought in a well last week that flows 300 barrels a day and is 740 feet deep.

The Arcata, between the Stratton property and the Altoona-Midway wells at Midway, at a depth of 1164 feet went into oil, and the sand rose nearly to the top of the casing.

MARIPOSA COUNTY.

McCarthy & Soderburg are developing their mine, near Kinsley, and intend putting in six more stamps, making it a 10-stamp mill, with water power from the Merced river.

The Austin Group M. & M. Co. is putting a steam hoist on the Coronado mine, near Whitlock. They also intend to put one on the Golden Gate, while the tunnel from the creek level on the Whitlock Chief mine will be driven ahead.

Weston, Patterson & Kinsley are working the Dugan mine, near Kinsley, under

hond, and last week made a mill run which returned \$20 per ton. The vein is 6 inches wide.

MONO COUNTY.

A new mining field is being developed between Oasis and Silver Peak, 12 miles from Oasis, says the Inyo Register. At present twenty men are at work, all on their own locations, besides the Hector M. Co., of which Hill & Barlow of Bakersfield are principal owners.

NEVADA COUNTY.

(Special Correspondence).—In Meadow Lake district five mining claims have been hounded to Los Angeles parties—Cash on the Dump, Sedgwick, Alice, Hattie and Angus. The property adjoins the Excelsior mine, now operated by the Crystal Lake M. Co. The Cash on the Dump G. M. Co. has been organized in Los Angeles; J. B. Ladd, president; J. M. Brown, secretary and treasurer; M. E. C. Munday, vice-president; R. Baker and J. D. Hoff, officers and directors.

The Crystal Lake G. M. Co. are running their ten stamps during the day only on ore from the Excelsior mine. The mine is not opened sufficiently to keep mill running the twenty-four hours. The output for the past five months has been between \$3000 and \$3300 per month. Recently a body of high-grade ore has been opened in the main tunnel. The manager, T. H. Murray, intends to develop the mine so that the mill may be run full time, and the addition of ten stamps more is being considered.

Emigrant Gap, Feb. 28.

The Murchie Con. G. M. Co. has been incorporated; C. F. Humphrey, B. Goodman, J. J. Meyers, A. Maltman, W. T. Farrar, J. C. Campbell. The Murchie mine is in Willow valley, near Nevada City. The company also owns the Lone Star and Alice Bell mines, adjoining the Murchie, and an 8-stamp mill, which is being overhauled. J. C. Cambell is manager.

The 20-stamp mill at the Red Cross mine, near Washington, is in operation.

The Alta mine, near Washington, has resumed after a temporary suspension on account of the heavy storms last month.

The Standard mine, near the Jenny Lind, near Grass Valley, will be reopened, says C. A. Emery, a Boston member of the company. The shaft is down 150 feet, where it is tapped by a drain tunnel 500 feet in length. It is the intention to continue sinking, following the vein. The company owns five full claims and a 20-stamp mill will be installed.

PLACER COUNTY.

The 5-stamp mill at the Crandall mine, near Auburn, is in operation. F. Hartley is superintendent.

At the Gaylord mine, near Auburn, the black sand which has heretofore been allowed to run to waste after being partially worked, has been found to run well in fine gold; it will hereafter be shipped to the Selby works for reduction.

SACRAMENTO COUNTY.

The Sutter M. Co. has put in an oil burner on their Keystone drill on the Murray ranch.

SAN BERNARDINO COUNTY.

The American Niter Co., G. E. Bailey, consulting engineer, and E. P. Ripley, part owner, controlling niter deposits near Daggett, will install this spring an experimental plant for developing their holdings in Death Valley. They have recently had surveying parties out, and it is said the company will soon have 300 men at work. There are other minerals found near the niter beds—horax, bicarbonate of soda and gypsum.

SANTA CLARA COUNTY.

Last week, after passing through 200 feet of clay, the Watsonville Oil Co., operating on the Sargents ranch, 7 miles south of Gilroy, struck the oil sand at a depth of 675 feet, the force of the oil and gas carrying the tools 40 feet in the air. The well is near the old tar spring, in which district the same company have struck several wells, this one being the eleventh and the second well yielding oil in paying quantities.

SHASTA COUNTY.

The Connor G. M. & M. Co. report a strike on the Connor group on Clear creek near the Mount Shasta mine, near Shasta. In the 120-foot tunnel they cut the ledge found on the surface, 100 feet above, and have opened 2 feet of sulphide ore showing free gold.

The Mount Shasta Gold Mines Corporation, F. E. Ware manager, has let contracts for further development of the Summit group on Backbone creek, near Kennett. The Mount Shasta mine, one of the group, has been equipped with electric power for the mill. Steam is still used for air compressor and hoist, but the company expects to put in a larger compressor this spring, when electricity will

be applied and compressed air used in running the hoist.

The gold mines of Old Diggings district, near Redding, have several shipments of quartz ready for hauling to the smelter at Keswick. Superintendent Woodrow of the Texas mine has 100 tons of quartz loaded on flat cars at Central Spur. The lessees of the Mammoth have sixty tons loaded and awaiting orders. C. Hoskins, lessee of the upper workings of the Texas mine, has two cars of assorted ore loaded. Other lessees at the Spanish and Central mines are preparing ore for shipment.

The Washington mine at French Gulch has twelve men at work and is taking out 200 tons of ore per month.

The Higbland quartz and placer mine, at French Gulch, has resumed under the superintendence of M. H. Peck.

SISKIYOU COUNTY.

(Special Correspondence).—The Ball mine has been sold to El Paso, Texas, men; \$10,000 has been paid; price, \$300,000.

Sawyer's Bar, March 2.

Boston men have bought the Commodore mine, Barkhouse creek, near Etna, says the Advance. Operators will begin this month and additions made to the plant. They expect to sink a shaft from the lower tunnel.

The Etna Advance says the Ball mine closed down temporarily last week, owing to the freezing spell. The aerial tramway is in operation. The company will add ten or twenty more stamps to their mill this spring.

TUOLUMNE COUNTY.

W. A. Holmes has begun work on the John Royal mine in Experimental gulch, above Columbia. He has put in a 100 H. P. hoist and intends sinking several hundred feet.

Fire partially destroyed the top works at the Del Monte mine, near Groveland, last week.

The mill test of ore from the crosscut at the 150-foot level of the Nonpareil mine, near Groveland, made last week, gave returns of \$5 per ton, free milling, says Superintendent Dron. The crosscut is 53 feet in length and the hanging wall has not yet been reached.

C. Richards is preparing to open up the Wheel Rough mine, near Soulsbyville.

At the Belle mine, near Tuttletown, the shaft is down 500 feet, the vein at that point showing free gold. A main three-compartment shaft will be sunk south of the present one.

At the Street mine, near Tuttletown, drifting is in progress on the 300-foot level north of the shaft, says Superintendent Kingman.

R. Hersey of San Jose, as trustee, has bought forty acres of placer ground near the Mayflower tunnel, 1 mile south of the Tuolumne river, near Groveland, says the Independent. Hersey, for \$4500, has also bought the Bright Star and New Discovery group of mines, near the Duleek mine.

The Independent reports the Springfield Tunneling Co.'s placer (Woodside gravel mine), on Table mountain, near Sonora, has been rebanded by the present operators to Philadelphia men for \$45,000.

The Horseshoe Bend G. M. Co. of Boston, Mass., last week bought for \$10,000 the Doyle mines, which divided the company's several claims on the Stanislaus river, near Columbia. The company now owns twenty claims and development work will begin this month.

Work on the Carlotta group of mines, near Carters, has begun under the superintendency of C. L. Lang, says the Democrat.

The Santa Ysaabel G. M. Co. has turned over all its property and assets to the Santa Ysaabel M. & M. Co., incorporated under the laws of Arizona. Certificates of the latter are being delivered upon the payment of the balance due of 10 cents per share. The new company starts with twice the area and with \$150,000 to \$175,000 cash on hand. The mine, near Stent, is being unwatered and machinery put in order.

COLORADO.

BOULDER COUNTY.

H. P. Walker, superintendent of the Ingram mine at Salina, says the mine has thirty men at work on leases.

CLEAR CREEK COUNTY.

The McClelland tunnel of the Monarch M., T. & P. Co. has opened a flow of water in the mine at Freeland, 2 miles west of Idaho Springs. This has increased until there is a stream averaging 3000 gallons a minute.

The Joe Reynolds mine, on the opposite side of the creek facing the East Red Elephant tunnel, near Lawson, has been drained by the tunnel run in on the Elida vein. This tapped the bottom of the Joe Reynolds shaft and has opened up the ore body showing workable values.

The Silver Standard says arrangements

have been completed and the contracts let for completing the Atlantic-Pacific tunnel near Silver Plume, which is in 6000 feet and will pass under Gray's peak. N. West is superintendent, and operations will begin as soon as supplies and machinery can be sent up to the tunnel.

CUSTER COUNTY.

The Gold Metal M. & M. Co. has been reorganized, with the addition of other mining territory, as the New Gold Metal M. & M. Co., by J. Schell of Querida and P. M. Finnis of Custer. The consolidation includes the Pochontas-Humboldt mines at Rosita, seven claims at Telluride, San Miguel county, and 16,870 acres of placer and lode ground in New Mexico. The first work of importance will be on the Pochontas-Humboldt or Rosita property, where the erection of a 50-stamp mill is proposed.

FREMONT COUNTY.

Announcement is made that the Portland Cement Co. will build a factory on the north side of the Arkansas river near Florence for the manufacturing of plaster of Paris from a bed of gypsum they have located there.

The Fremont coal mine, near Rockdale, under operation by the Colorado F. & I. Co., has been equipped with an electric lighting plant. The main workings underground, as well as on top, are lighted. The coal is mined by electric drills.

The seepage from the clear water wells drilled by the Colorado Springs & Florence Oil & Gas Co., near Chandler, is said to be flooding the lower side of the Chandler mine, and a portion of that end of the mine is being abandoned. Electric pumps are being used to reduce the water. The three wells are a mile from the mine and the flow is 360,000 gallons per day. The water will be piped along the Arkansas river and used in Pueblo for domestic purposes. The company will drill other wells. They were drilling for oil when they tapped this underground reservoir.

The Union mill, near Florence, is in operation, with 200 men at work and handling 450 tons per day. Five furnaces are in operation.

Enlargements in the roaster, concentrator and precipitating departments of the Dorcas mill near Florence are being made. The plant is treating 100 tons a day.

GILPIN COUNTY.

Last week the 50-ton concentrator and stamp mill in Chase gulch, near Central City, was started up. The plant was built by the Lyons-Kyle G. M. & M. Co., W. Wood superintendent, to handle the ores of the Tucker mine. The plant is driven by steam power; they have an ample water supply and have built several storage reservoirs for winter use. The buildings are lighted by electricity.

The Gunnell M. Co., near Central City, has resumed and are unwatering the mine. Below the Gunnell and on the same hill, the Buckley mine has resumed and is making regular shipments of ore.

The Fostoria G. M. Co., B. M. Myers superintendent, operating the Hall ranch group near Central City, will enlarge their plant and put in heavier machinery.

Jones, Hardy & Miller of Russell Gulch have taken a lease on the Defiance mine, near Russell Gulch, and have begun work in the lower levels to get under the chute of ore which was found on the 100-foot level.

The Avon mill, in Nevada gulch, near Nevada, is in operation with twenty stamps dropping on ore from the San Juan mine, on Quartz hill, which is delivered by tramway.

GUNNISON COUNTY.

A coal camp is building up at Somerset, in the northwestern part of the county. A vein of first-class coal is being worked by the Wasatch Coal Co. of Utah with 150 men employed. The company is installing a set of four scales to cost \$10,000. The location is 2 miles from the Delta county line and near the Dorrance, Gelwich and Juanita banks.

The Rosalasa M. Co. has leased the Granite Mountain group in Jones' gulch, near Pitkin, for two years, and work was started up last week.

LAKE COUNTY.

Near the Valley mine, near Leadville, the Blue Ribbon mine is being worked by local lessees headed by T. V. Gallagher. They are sinking a new shaft with three shifts and expect to tap the Valley ore chute at about 160 feet.

The American S. & R. Co. have their sulphide mill at the A. V. plant at Leadville in operation, beginning with a capacity of 300 tons a day.

Surface improvements are under way at the Coronado mine, near Leadville. The boilers are being overhauled and pumping will be resumed next week. The retimbering of the shaft is completed, says Superintendent D. Jones.

Manager McGreevy of the Catalpa-

Crescent, near Leadville, is taking out three products from the discovery shaft—a good grade of lead, an oxidized iron and manganese which goes to the steel works at Pueblo—a total of thirty tons a day.

Superintendent Johnston of the Big Six mine, near Leadville, reports having finished sinking an additional 107 feet on the Little Prince shaft, and, after going through 60 feet of quartzite, cut an intrusive sheet of porphyry. At this point he proposes to run drifts and prospect east and west.

Superintendent G. Campion of the Little Bob mine at Leadville says the contact ore body cut last week has been opened up, showing 60 feet thick. It assays \$5 in gold and one and one-half ounces in silver and a cyanide plant will be installed. The ore lies between porphyry and quartzite walls and is a body of decomposed quartz.

Manager F. Brooks reports opening up the extension of the Resurrection ore chutes in the Diamond mine, near Leadville, at 200 feet in on the drift from the 1020 foot point in the shaft. A larger hoist and other machinery will be put in and shipments started.

There are 200 men at work in the Moyer mine, near Leadville, says Manager J. Walsh, and the present working shaft is being taxed to its full capacity. The North Moyer shaft will be down to the level driven out of the ore stop by the 10th inst., and a heavier hoist will be installed there, after which it is expected to increase the output of the mine by one-half the present tonnage.

A. J. Andrews of Montreal, Canada, part owner in the Dolly B mine near Leadville, has closed down the property, owing to a disagreement among the owners as to their operating policy, says the News-Dispatch.

MINERAL COUNTY.

Manager Fitzgerald of the Humphrey mill, near Creede, says the new assay office on the floor of the first set of rolls is completed. Everything is automatic, samples are conveyed from automatic sampler to crushers and rolls from which pulp moves through troughs to screens, the oversize carried back for regrinding, while screenings are delivered on bucking-board.

The Big Kanawha (United Mines Co.), near Creede, instead of depending on the water power in future will put in a steam plant to be used in the fall and winter months when water is short. As soon as the snow melts in sufficient quantity the Humphrey mill will resume and run at rate of 350 tons of ore per day, says Manager Fitzgerald.

The Captive Inca mine, between the Antlers-Park Regent group and the continental divide, near Creede, is being developed as a gold producer, with W. G. Boyle, manager. J. R. Hanna of Monmouth, Ill., is president of the company. A contract has been let to sink a shaft 5 by 15 feet to a depth of 500 feet. The company expects to sink this shaft to 800 feet, from which point they will drift to the Bachelor mountain vein.

OURAY COUNTY.

The Treasure tunnel at Red mountain has closed down indefinitely after being driven 4900 feet on its course toward Telluride. The shut down is owing to litigation over the right of the tunnel to pass through a prior location on its line, says the Standard.

PARK COUNTY.

It is reported the Snowstorm Hydraulic Co. is to absorb the Alma placers, which include most of the Platte River valley from a point 1 mile below Alma up to Montgomery, 6 miles above, including the priority water rights. The Snowstorm Hydraulic Co., organized by Colorado and Eastern men, own the placer lands from a point half way between Alma and Fairplay, extending to below the latter town, known as the Snowstorm and Beaver Park placers. Manager Evans of the Goldpan Co., at Breckenridge, is part owner.

SAN JUAN COUNTY.

The Mammoth T. & M. Co.'s holdings in Prospect basin, near Silverton, consisting of twenty-eight claims, tunnel site, millsite, water right, etc., has been bonded and leased to the Stony Pass M. Co., A. A. Brown, manager, for fifteen years. The tunnel will be extended 500 feet additional, and the Hercules, one of the group, will be equipped with a steam hoist.

The Stony Pass M. Co. has incorporated to operate the C. A. Marshall group in the Stony Pass section, near Silverton. A. W. Hall, F. Jones, W. A. Brown, W. F. Pope of Maine, J. F. Shafer. A. A. Brown of Silverton is manager and superintendent.

SUMMIT COUNTY.

The Mountain Pride Co. shut down last week for repairs in the mill, after a continuous run of fourteen months. The

snow made it impossible to keep a wood supply on hand.

The Robinson pyritic smelter, at Robinson, will be blown in April 1, says Superintendent Doolittle.

TELLER COUNTY.

The Cripple Creek Times says the value of tonnage of ore produced from the mines of Cripple Creek district for February amounted to \$1,651,970, from 51,674 tons of rock crushed:

	Tons.	Average Value.	Value.
Smelter....	9,000	\$55 00	\$495,000
Economic....	5,000	27 50	137,500
Dorcas.....	3,200	37 50	120,000
Aurea.....	1,774	5 00	8,870
U. S. R. & R. Co.....	25,000	27 00	675,000
Portland....	7,700	28 00	215,600
Total..	51,674		\$1,651,970

This production is less than for some months past, the shortage being partly due to severe weather and a temporary breakdown of the La Bella power plant, which supplies several of the mines with air. The Colorado plant of the United States R. & R. Co. was closed fifteen days of the month. Repairs are being made to that plant. Figures from the Telluride mill were not obtainable.

The Jack Martin Leasing Co., leasing the Guyot hill property of the Robert Burns Co., near Cripple Creek, are operating through the tunnel level, where a winze has been sunk to 200 feet, giving 400 feet depth below the surface. Drilling is in progress from the bottom of the winze in a southeasterly direction to explore the country. Ore has been cut assaying \$10.

The Times reports a new ore shoot to Gold hill opened in the second level of the main workings of the Lexington Co., adjoining the Anchoria-Leland, at Cripple Creek. Lawry & Miterer are operating the property under a bond and lease. The vein lies northwest of the shaft and is 3 feet wide, assaying \$18 in gold. The ore shoot has been proven in length for 35 feet.

The Gold Cord M. & S. Co. has a lease on blocks 13 and 14 of the Bonanza King, on Gold hill, Cripple Creek, and a steam hoist will be installed.

The Doorkey G. M. Co. last week received a patent on the Malta claim of 49 acres on Galena hill, near Cripple Creek. The company also owns the McCumber-Morning Star and Doorkey claims on Tenderfoot hill. A. F. Woodward is president.

The cyanide plant of Nesbitt & Miller at Cripple Creek is in operation and handling rock from the Pharmacist dump at the rate of thirty tons a day.

The territory owned by and under lease to the Moose Co., on Raven hill, Cripple Creek, is being prospected by diamond drilling.

Lateral work has been started by the Cripple Creek Enterprise G. M. Co., at Cripple Creek, at a depth of 200 feet.

The Cripple Creek & Pueblo Railroad is driving a 4 mile tunnel, double-track width, from Cripple Creek to Victor. The engines will haul fifty cars at a time. The plan is not to mine, but to transport ore from underground workings to mills and smelters, saving the cost of hoisting. The freight rate will be 50 cents a ton for dirt and \$1 a ton for ore. The main tunnel will be straight and level, but branches will be run on irregular grades to reach important mines. Work was begun Jan. 1 and they are making the record of 30 feet per day. The Mary McKinney, Doctor-Jack Pot and Anaconda mines have already been reached at from 600 feet to 1000 feet depth. The greatest depth, 1550 feet, will be reached this month.

The Cripple Creek Times reports an option has been given on the controlling interest of the Golden Cycle mine, on Bull hill, Cripple Creek, to W. H. Reynolds of New York.

The El Paso Co. have three shifts at work in their third level, at depth of 490 feet, drifting on the C. K. & N. toward the latter property, and expect by March 10 to tap the water and drain the C. K. & N. shaft. The El Paso Co. is breaking the ore 34 feet wide, all of it being shipped smelting grade.—Development is being done in the east vein of the Little May, with stoping in progress in the first level, breaking two-ounce gold ore. The company is shipping two carloads a day of smelting ore. At present there are six sets of lessees operating on the company's holdings, with five of them on the shipping list.

The Hawkeye claim, at the head of Barnard creek, near Cripple Creek, will be operated by the Hawkeye G. M. & M. Co., incorporated last week; W. A. Parkinson, F. A. Wright, W. E. Lloyd.

A plant of machinery will be placed over the shaft of the Blue Flag on Raven hill, Cripple Creek, owned by a Denver company. An old shaft has been retimbered and the collar raised.

IDAHO.

CUSTER COUNTY.

The Shakespeare lode, on Loon creek, running parallel with that of the Lost Packer, says E. Macheth of Custer, shows 3 feet of ore at the surface running \$30 gold per ton.

ELMORE COUNTY.

The General Pettit mine, near Atlanta, has been sold to New York men for \$130,000. A cyanide plant will be installed this spring.

IDAHO COUNTY.

F. Brown, manager of the Jumbo mine at Buffalo, reports that his company will build a 20-stamp addition to their mill. He says: "We have between \$12,000 and \$15,000 worth of the second-grade ore awaiting the erection of a cyanide plant. The tailings will be treated by the same process. There are 1 1/2 year's run of tailings from the 4-stamp mill stacked up, which assays \$5 per ton. Work is progressing on the lower ore shoot. It has been crosscut every 50 feet, and in each drift its width is 11 feet. The Jumbo, with four stamps, is producing \$5000 each month. The total output of the district from the four mines, operating twenty-nine stamps, is about \$20,000 per month."

H. L. Hollister, acting for Chicago men, has bought the Homestake & Idaho group of seventeen claims for \$125,000. The mines are on Beaver creek, in the Thunder Mountain district, near Thunder.

KOOTENAI COUNTY.

F. G. Jordan, of Spokane, Wash., manager of the Pacific Portland Cement Co., operating in the Pend d'Oreille district, near Sandpoint, says the Pacific Portland Cement Co. has its works on the Pend d'Oreille river, 52 miles southeast of Northport, Wash., and when the plant is complete will turn out 100 barrels of cement daily. The company has 400 acres of land producing cement materials, above the works, and 1250 feet above steamboat level. The machinery for the works will be run by water power. The cement is taken down the river by steamboat to Northport, then shipped to Spokane.

In the lower workings on the War Eagle claim, owned by the Tyson Con. M. Co. at Tyson, and adjoining the Richmond on the east, the ledge was crosscut last week. It shows 12 feet wide and carries free gold.

The Panhandle S. & R. Co. of Minnesota men plan the erection of a smelting plant at Sand Point, and it is intended to have the works in operation by September. The work of excavation has begun. One furnace of 300 tons daily capacity will be installed at first and gold, silver and copper ores reduced. A waterfall 300 feet high, 1 1/2 mile from the smelter site, will furnish 1000 H. P., says Superintendent H. M. Williams. The Queen Aoo mine, owned by the Panhandle Co., contains deposits of iron ore averaging 18%. Mixed with this ore is lime rock, making it a flux for the silver and lead ores of the district. The Queen Ann is on Trestle creek, within easy access of the smelter. The company have bought a number of boats and from the mines of the northern districts ores can be shipped across Lake Pend d'Oreille at a cost of 50 cents per ton.

OWYHEE COUNTY.

At De Lamar, says the Nugget, the De Lamar Co. is taking out 180 tons of ore per day, which is handled by their concentrating mill.

Electric drills have been installed at the Alta-Vista mine, near Silver City.

Manager A. G. Stephens says a strike was made in the group of the Traders' M. Co. on a drift driven from the main workings of the mine, opening a 5-foot vein of free milling gold ore which assays \$30 per ton.

SHOSHONE COUNTY.

L. W. Stedman, manager of the Paragon mine at Murray, says the shaft is down 80 feet. The machinery for the hoist and pumps has been installed. They will sink 300 feet and then run a crosscut for 145 feet, at which point it is expected the lead will be cut.

The Sterling M. Co., owning a group of seven claims on Lake gulch, south of Osburn, filed articles of incorporation last week; A. Murphy, J. Presley, W. W. Woods, M. Presley of Wallace and W. H. Myers of Mullan.

The sampling works below Wallace report that the tonnage sampled during January amounted to 13,485 tons, which exceeds that of previous months by 3000 tons. Further additions will be constructed and then the plant will be able to treat 15,000 tons per month.

A strike is reported made on the Sparrenberg group on Big creek, near Mullan. The ledge was cut by the tunnel at 300 feet and shows 3 feet of ore carrying 10%

copper, 12 ounces silver and \$5 in gold.

The Springfield mine, on Stevens peak, has resumed. There are a number of other properties that will start up this month, among which is the Flinn group, adjoining the Morning mine.

Another shoot of concentrating ore, thought to be running out from the main ledge, was cut on the Humming Bird silver-lead group, near Burke, last week. The property is north of the Tiger-Poor-man, the mouth of the tunnel being on the ground of the latter. The vein has been exposed in the upper workings. The tunnel is in 1500 feet.
